Key words: Triterpenoid, alkaloid, Melochia umbellata, antimicrobial, anti-HCV.

ABSTRACT
Two triterpenoid and alkaloid compounds have been isolated, namely, 3-acetyl-12-en-28-oic acid and (R)-N-trans-feruloyloctopamine from Melochia umbellata (Houtt.) Stapf var Visenia. Both of these compounds were tested as an antimicrobial and anti-HCV activity. Isolation has been done by maceration, fractionation, and purification. The molecular structure was determined by IR spectroscopy and nuclear magnetic resonance (NMR) 1,2D (¹H-NMR, ¹³C-NMR, HSQC, and HMBC). Antimicrobial assay of 3-acetyl-12-en-28-oic acid showed a zone of inhibition in the criteria of moderate to active against Escherichia coli (8.4 mm), Salmonella typhi (11.2 mm), Staphylococcus aureus (10.8 mm), and Candida albicans (8.5 mm), as well as compounds (R)-N-trans-feruloyloctopamine that is against E. coli (7.0 mm), S. typhi (10.55 mm), S. aureus (9.1 mm), and C. albicans (7.9 mm). Anti-HCV tests on the two compounds showed IC₅₀ values of 52.07 and 45.02 µg/ml, respectively. The results of these tests indicate that the two compounds are potential as an antibiotic candidate.

INTRODUCTION
Microbial infections, such as bacteria, fungi, and viruses, are a cause of morbidity and mortality worldwide (Ndhlala et al., 2013). Some diseases caused by microbial infections include tuberculosis, typhus, diphtheria, cholera, dysentery, and pneumonia (Wagner et al., 2017). While viral infections can cause various diseases, like hepatitis C, it is also a worrying global problem (Emanuelli et al., 2014), infecting nearly 170 million people worldwide (Mustopa et al., 2012; Tumewu et al., 2016). Hepatitis C virus is a member of the genus Hepacivirus and the family Flaviviridae (Adianti et al., 2014). This disease is difficult to cure because there are no specific drugs or vaccines, such as hepatitis A and B (Mustopa et al., 2012), with increasing cases (Hsueh et al., 2016). HCV can cause acute liver disease and cirrhosis liver which can potentially lead to liver cancer (Mustopa et al., 2012).

Increased resistance to antibiotic and anti-HCV drugs requires the search for new antibiotic and anti-HCV drugs. Plants are a source of secondary metabolites with diverse molecular structures that can be used as drug candidates or lead compounds in the discovery and development of new drugs (Gupta et al., 2014; Li et al., 2013). Melochia is a genus of the Malvaceae family, spread from India to Southeast Asia and Papua New Guinea. Currently, the genus Melochia is reported to consist of 65 species (Machado and Sazimab, 2008). Melochia umbellata (Houtt.) Stapf is one of the species of medicinal plants of the genus Melochia on Sulawesi Island (Indonesia). This species consists of two varieties, namely, degrabrata and visenia variety. Some studies on this species show a variety of chemicals, such as flavonoids, terpenoids, coumarin, alkaloids, and quinones.

Some compounds and bioactivity of M. umbellata (Houtt.) var Degrabrata have been reported, such as stigmast-5,22-dien-3O-β-D-glucopyranoside against Aspergillus niger (Ridhay et al., 2012), and 3-acetyl-12-olean-28-oic acid active against Bacillus subtilis and C. albicans (Usman et al., 2014). 6,6′-dimethoxy-4,4′-dihydroxy-3′, 2′-furano-isoflavan compounds (Erwin et al., 2010),

methyl b-(p-hydroxyphenyl) acrylic (Soekamto et al., 2008), and walterion C exhibit anticancer activity (Erwin et al., 2014). The leaf extract of M. umbellata (Houtt.) Stapf var degrabrata can protect inflammation of the liver (Raflizar and Sihombing, 2009), antioxidant activity, and moderate cytotoxic activity against HepG2 liver cancer cells (Arung et al., 2009).

The finding of the phenol alkaloid (R)-N-trans-feluroyloctopamine (2) compound from the plant M. umbellata (Houtt.) Stapf var Visenia has been reported previously (Nusan et al., 2019). In this paper together with a compound of 3-acetyl-12-en-28-oic acid, the activity of both compounds as antimicrobial and anti-HCV will be reported. The molecular structure of (R)-N-trans-feluroyloctopamine (2) is shown in Figure 1.

MATERIALS AND METHODS

A liquid vacuum chromatography equipment, press column chromatography, gravity column chromatography, thin-layer chromatography, and chromototron were used for isolation; Fisher John melting point apparatus was used to determine the melting point of the compounds. The Fourier-transform infrared spectroscopy (FTIR) 8,501 Shimadzu and 1H-NMR Agilent 500 were used in spectroscopy.

Materials

Materials used in this study are a sample of the root timber of M. umbellata (Houtt.) Stapf var. Visenia. The sample was determined by Keragaman Flora Indonesia, Makassar (Indonesia). The organic solvent used quality p.a and technical that is n-hexane, chloroform, ethyl acetate, acetone and methanol, silica gel Merck (7,730, 7,733, and 7,734), and cerium sulfate solution 2%.

Isolation and spectroscopic analysis

The extraction is done by the total maceration method. First, the root timber powder M. umbellata (Houtt.) Stapf var Visenia was macerated using methanol and then partitioned liquid–liquid using a solvent: n-hexane, chloroform, ethyl acetate, acetone and methanol, silica gel Merck (7,730, 7,733, and 7,734), and cerium sulfate solution 2%. The extract was evaporated until it is dried. Furthermore, the MHA media was added to the test bacteria using a micropipette, agar media that had been added to the test bacteria vortex, poured into a sterile petri dish, and shaken so that the bacteria mixed evenly with the MHA media. The media is allowed to stand in aseptic laminar until it is frozen. Each disc paper was placed in a cup using sterile tweezers and incubated at 37°C for 18–24 hours. The antibacterial activity can be seen by observing the zone of inhibition formed around the disc paper. After finding out the diameter of the inhibition zone formed on the petri dish, the width of the inhibition zone formed using the calipers was measured. The amount of the inhibition zone is measured by reducing the inhibition zone formed on the test petri dish with the diameter of the disc paper.

The antifungal assay is carried out with the same procedure as an antibacterial assay, but using PDA media.

Analysis of anti-HCV activities

Seeding was performed in 48 wells with a cell density of $5.4 \times 10^{4}$, 24-hour incubation. After incubation add JFH1a virus titer $6.9 \times 10^{6}$ with m.o.i 0.1 and the sample in each well is 100 μl from each dilution. In this study, concentrations of test materials were made 100, 50, 25, 12.5, 6.2, 3.1, and 1.56 μg/ml. Furthermore, 48 hours of incubation were carried out and supernatant from each concentration was taken to calculate the titer. The calculation of infected cell titer is done using the same method, namely, on a multiwell plate 96 well. Next, it was incubated for 48 hours and was fixed for further staining using DAB thermo staining. Infected cells show a brown color. The inhibition percentage of virus infectivity by the samples was calculated by comparing to the control using SPSS probit analysis, and IC_{50} values were determined.

RESULTS AND DISCUSSION

Isolation

The plants bark powder of M. umbellata var. Visenia plants (10 kg) were extracted by maceration with methanol 1 × 24 hours (three times). The methanol extract was concentrated by a low-pressure rotary evaporator and methanol extract (116.26 g) was obtained. The methanol extract was partitioned with liquid–liquid extraction using solvents with increasing polarity; n-hexane, chloroform, and ethyl acetate. At the root timber obtained n-hexane extract as much as 10.24 g, chloroform extract 41.28 g, and ethyl acetate 11.1 g.

Extract n-hexane as much as 10.0 g was fractionated using a vacuum liquid chromatography method using n-hexane eluent (100%), n-hexane: ethyl acetate in stages from a ratio of 19:1 to 1:9, ethyl acetate (100%), and methanol (100%), obtained

Figure 1. The molecular structure of (R)-N-trans-feluroyloctopamine (2).
4 fractions (A–D), namely, fraction A (0.23 g), fraction B (4.89 g), fraction C (2.60 g), and fraction D (0.57 g). The profile spot of n-hexan extract is shown in Figure 2.

Fraction C as much as 2.00 g was carried out press column chromatography using eluent n-hexane: ethyl acetate with a ratio 9.5:0.5, 9:1, 8:2, 3:7, and 1:1, resulting in six subfractions (Ca-Cf) namely, subfraction of Ca (0.41 g), subfraction of C.b (0.81 g), subfraction of C.c (0.26 g), subfraction of C.d (0.19 g), subfraction of C.e (0.21 g), and subfraction of C.f (0.20 g). Furthermore, as much as 200 mg of subfraction C.b was fractionated by the chromatotron method using eluent n-hexane: chloroform with a ratio of 7:3, resulting in five sub-subfractions namely, C.b1 (0.003 g), C.b2 (0.004 g), C.b3 (0.012 g), C.b4 (0.033 g), and C.b5 (0.057 g). The Cb.5 is fractionated again by the gravity column chromatography method using eluent n-hexane: diisoprophyl ether with a ratio of 8:2, resulting in three sub-subfractions, namely, C.b51 (7.0 mg), C.b52 (11 mg), and C.b53 (17 mg). The C.b51 in the form of a white crystal weighing 7.0 mg in thin layer chromatography analysis showed a single stain reinforced by sharp melting point intervals, indicating that the compound was pure (1). The profile spot of compound (1) is shown in Figure 3.

Elucidation structure (1)

Compound (1) formed white crystals with melting point 280°C–282°C. The IR Spectrum Compound (1) shows the absorption at wave number 3,217.27 cm⁻¹ for OH, strong and sharp absorption at 1,728.22 cm⁻¹ and 1,681.63 cm⁻¹ for the carbonyl group (C=O) for esters and carboxylic acids and 1,251.80 cm⁻¹ for C-O ester single bonds and 1,028.06 cm⁻¹ for C-O carboxylic acid single bonds. The strong and sharp absorption band at 2,943.37 cm⁻¹ as a C-H bond of aliphatic reinforced by absorption band at 1,463.97 cm⁻¹ which is the C-H bending of the CH₂ group. The IR Spectrum of compound (1) is shown in Figure 4.

The ¹H-NMR spectrum shows the presence of proton signals in the chemical shift at δ₁ 5.28 ppm as signal of 1H (H-12) and 8 signals of 3H that is δ₁ 0.87 ppm (H-23), δ₁ 0.86 ppm (H-24), δ₁ 0.95 ppm (H-25), δ₁ 0.75 ppm (H-26), δ₁ 1.14 ppm (H-27), δ₁ 0.91 ppm (H-29), δ₁ 0.94 ppm (H-30), and δ₁ 2.05 ppm (H-32).

The ¹³C-NMR spectrum showed 32 carbon signals in the chemical shift between δc 15.37 ppm to 183.43 ppm. In the aliphatic region, 28 carbons were found, including one signal of a hydroxyl methine carbon at δc 80.91 ppm (C-3). In the alkene region, signal = CH-alkene was found at δc 122.54 ppm (C-12) and signal = C-quadernier at δc 143.58 ppm (C-13). Whereas in the carbonyl group region found a carbonyl group at δc 183.43 ppm (C-28) which was identified as the carboxylic acid and carbonyl group at δc 171.00 ppm (C-1′) which was identified as the ester.

Based on the HSQC spectrum, it can be explained that in the aliphatic carbon region there are 22 correlations, with details of 8 methyls (CH₃), 10 methylenes (CH₂), and 4 methines (CH). In the alkene region, one methine (=CH) was identified at δc 122.54 ppm (C-12). The quaternary carbon was found in the alkene region at δc 143.58 ppm (C-13), carbonyl groups at δc 171.00 ppm (C-28) as the ester, and carbonyl groups at δc 183.43 ppm (C-1′) as the carboxylic acid. The molecular formula for this compound is C₃₂H₅₀O₄, which has a DBE value of 8, with the details of 1 DBE for the alkene double bond (C-12/C-13), 2 DBE for the double bond on the carbonyl ester and carboxylate. Therefore, the
remaining 5 DBE must be 5 rings. Thus this compound is a 5-ring cyclic compound, which having one alkene bond at C-12,13, and substituent of methyl, hydroxyl, carboxylic, and ester. Based on these characteristics, this compound is recommended to be the skeleton of a pentacyclic triterpenoid.

The HMBC data of the compound of (1) showed that protons at δ_h 0.87 ppm (H-23) correlated distance with quaternary carbon at δ_c 37.68 ppm (C-4), methoxy carbon at δ_c 80.91 ppm (C-3), methyl carbon at δ_c 55.28 ppm (C-5), and methyl carbon at δ_c 16.65 ppm (C-24). These HMBC correlations explain that the two methyl groups that is at δ_c 28.027 ppm (C-23) and δ_c 16.65 ppm (C-24) ppm both of which have geminal positions as substituents bound to the quartener carbon at δ_c 37.68 ppm (C-4) at the ring A of the pentacyclic triterpenoid skeleton.

Methyl protons at δ_h 1.14 ppm (H-27) correlate distance with quaternary carbon at δ_c 143.58 pm (C-13), methylene carbon at δ_c 27.65 ppm (C-15), quartener carbon at δ_c 39.27 ppm (C-8), and carbon quartener at δ_c 41.55 ppm (C-14). Methyl protons at δ_h 0.76 ppm (H-26) correlate distance with quartener carbon at δ_c 39.27 ppm (C-8), quartener carbon at δ_c 41.55 ppm (C-14), methylene carbon at δ_c 32.43 ppm (C-7), and methyl carbon at δ_c 47.54 ppm (C-9), while methyl proton at δ_c 0.94 ppm (H-25) correlates remotely with carbon methine at δ_c 47.54 ppm (C-9), carbon methylene at δ_c 38.06 ppm (C-1), and quartener carbon at δ_c 36.97 ppm (C-10). This HMBC correlation data explains that the methyl group at δ_c 25.88 ppm (C-27) is a substituent bound to the quartener carbon atom at δ_c 41.55 ppm (C-14), the methyl group 17.15 ppm (C-26) as a substituent bound to quartener carbon at δ_c 39.27 ppm (C-8), and methyl group at δ_c 15.37 ppm (C-25) as substituents bound to carbon quartener at δ_c 36.97 ppm (C-10).

Methyl protons at δ_h 0.91 ppm (C-29) correlate distance with methyl carbon at δ_c 23.56 ppm (C-30), while methyl protons at δ_h 0.94 ppm (C-30) correlate distance with quartener carbon at δ_c 30.66 ppm (C-20) and secondary carbon atom at δ_c 45.83 ppm. This HMBC data explains that both methyl are substituents with geminal positions that are bound to quartener carbon atoms at δ_c 30.66 ppm (C-20), showing this compound is typical for ß-amyrin. The proton methane at δ_h 2.82 ppm (H-18) correlates distance with carbon methine C-sp^3 at δ_c 122.54 ppm and C-sp^2 quartener carbon at δ_c 143.58 ppm supporting these two C-sp^2 as vinyl groups, respectively, in C-12 and C-13, confirm this compound as oleane. Besides, the distance correlation between methyl protons at δ_h 2.82 ppm (H-18) and quartener carbon at δ_c 183.43 ppm (C-28) confirms that the carboxyl group is a substituent bound to C-17, which is common in oleane containing carboxyl group.

Searching literature shows that compound (1) is a known oleane, as well as that found in M. umbellata (Houtt.) Stapf var Degabrata that is compound of 3-acetyl-12-oleanen-28-oic acid (Usman et al., 2014). Data interpretation of ^1H-NMR, ^13C-NMR, HSQC, and HMBC data is presented in Table 1, while the correlation of HSQC, HMBC, and the molecular structure of compound (1) is shown in Figure 5.

**Biogenesis of (R)-N-trans-feruloyloctopamine (2)**

The biosynthesis of compounds (R)-N-trans-feruloyloctopamine in plants is generally thought to originate from condensation and reduction of octopamine and ferulic acid. The two compounds are derived from a shikimate acid pathway starting from the condensation of erythrose-4P and PEP to produce 3-deoxy-D-arabino-heptulosonic acid 7-phosphate (DAHP). DAHP through a series of reactions, like aldol condensation, which involving several enzymes as catalysts, forming shikimic acid (Dewick, 2002; Parthasarathy et al., 2018). Through shikimic acid condensation and PEP, chorismic acid is formed, which then undergoes a series of rearrangement reactions to form prephenic acid (Dewick, 2002). Prephenic aminotransferase is an enzyme whose role is to convert prephenic acid into arogenic acid. Arogenate is the exclusive precursor of Phe/Tyr in many plants (Lewis and Yamamoto, 1990).

Pathways to the aromatic amino acids L-phenylalanine and L-tyrosine via prephenic acid may vary according to the organism, and often more than one route may operate in a particular species according to the enzyme activities that are available (Dewick, 2002). In arogenic acid 2 new biogenesis pathways are formed, one dehydrogenates to form tyrosine and the other to form phenylalanine. Arogenate dehydratase is an enzyme that plays a role in the metabolism of L-phenylalanine, while arogenate dehydrogenase is a role in the metabolism of L-tyrosine. All enzymes synthesizing Phe/Tyr have been found in the chloroplast, some evidence suggests that a dual pathway may exist in the cytosolic (Lewis and Yamamoto, 1990).

Phenylalanine undergoes a deamination reaction to form cinnamic acid, which then undergoes a hydroxylation reaction to form p-coumaric acid. Ferulic acid undergoes oxygenation to form trans-cafeic acid (cafeoyl), then undergo methylation to form ferulic acid (Dewick, 2002). In other pathways, phenylalanine can undergo oxygenation to form tyrosin (Dewick, 2002; Parthasarathy et al., 2018). Tyrosine can also form a pathway to produce p-coumaric acid and its derivatives (Dewick, 2002). In another pathway, tyrosine decarboxylase converts L-Tyrosine to Tyramine, and tyramine is metabolized by the Tyramine β-hydroxylase to Octopamine (D’Andrea et al., 2019; Farooqui, 2012; Parthasarathy et al., 2018).

In the final, octopamine (p-octopamine) condenses with ferulic acid to form (R)-N-trans-feruloyloctopamine. This condensation reaction is stereospecific in which a trans product is formed, followed by a reduction reaction in the form of the elimination of the OH group in ferulic acid. The organic reactions between octopamine and ferulic acid and other compounds in this group have been proven by a series of synthesis experiments of several researchers (Firdaus et al., 2018). However, it still needs to be understood that the biosynthesis of organic compounds in nature may be more complicated and not really the same as the synthesis process in the laboratory. The biogenesis pathway for compounds (R)-N-trans-feruloyloctopamine is shown in Figure 6.

**Antimicrobial and anti-HCV assay**

The results of the antimicrobial assay of compounds isolated against *E. coli, S. typhi, S. aureus, and C. albicans* are presented in Table 2.

A compound with an inhibition zone diameter of less than 5 mm is categorized as weak, inhibitory zones between >5 and 10 mm are categorized as a medium, inhibitory zones >10–20 mm are categorized as strong, and inhibitory zones >20
mm are categorized as very strong (Claude et al., 2014). Table 2 shows that compound (1) and Compound (2) are categorized as having moderate-to-strong inhibition against E. coli, S. typhi, S. aureus, and C. albicans. The antibacterial test data above shows the tendency of the two compounds as found in many antibiotic compounds, which have relatively stronger antibacterial activity against Gram-positive bacteria (E. coli dan S. typhi) than Gram-negative bacteria (S. aureus), perhaps is related to the cell wall layer of Gram-positive bacteria that are not as thick as and complex as Gram-negative bacteria.

The results of the anti-HCV assay 3-acetyl-12-oleanen-28-oic acid (1) and (R)-N-trans-feruloyloctopamine (2) against JFH1a virus showed IC$_{50}$ values of 52.07 and 45.02 μg/ml, respectively. A compound is said to be active as anti-HCV if the IC$_{50}$ value is less than 30 μg/ml (Versiaty et al., 2014), and can be categorized as very active if the IC$_{50}$ value is less than

*Usman et al. (2014)
Melochia umbellata (Houtt.) Stapf var Visenia is one of the Paliasa species, in the province of South Sulawesi (Indonesia) used traditionally as an anti-liver drug in the form of extracts, but currently unknown active compounds as anti-liver (anti-hepatitis) activities (Raflizar and Sihombing, 2009; Noor et al., 2004). The results of the antihepatitis C test on the two compounds (1,2) specifically showed that they were not responsible for the anti-liver activity of M. umbellata (Houtt.) Stapf var Visenia extract based on the IC\textsubscript{50} values above, but it was suspected that both, specifically the compound (2) with IC\textsubscript{50} values close to moderate, it contributes with other active compounds (unknown) to the antiliver activity of these plant extracts.

CONCLUSION

Has been isolated from the root timber of M. umbellata (Houtt.) stapf var visenia (Paliasa), a pentacyclic triterpenoid compound that is 3-acetyl-12-oleanen-28-oic acid. Compounds 3-acetyl-12-oleanen-28-oic acid and (R)-N-trans-feruloyloctopamine are potential as antibiotic candidates.
