Abstract
Modification of serine and threonine residues in proteins by O-linked β-N-acetylglucosamine (O-GlcNAc) glycosylation is a feature of many cellular responses to the nutritional state and to stress. O-GlcNAc modification is reversibly regulated by O-linked β-N-acetylglucosamine transferase (OGT) and β-D-N-acetylglucosaminase (O-GlcNAcase). O-GlcNAc modification of proteins is dependent on the concentration of uridine 5’-diphospho-N-acetylgalosaminose (UDP-GlcNAc), which is a substrate of OGT and is synthesized via the hexosamine biosynthetic pathway. Immunoblot analysis using the O-GlcNAc-specific antibody CTD110.6 has indicated that glucose deprivation increases protein O-GlcNAcylation in some cancer cells. The mechanism of this paradoxical phenomenon has remained unclear. Here we show that the increased glycosylation induced by glucose deprivation and detected by CTD110.6 antibodies is actually modified by N-GlcNAc2, rather than by O-GlcNAc. We found that this induced glycosylation was not regulated by OGT and O-GlcNAcase, unlike typical O-GlcNAcylation, and it was inhibited by treatment with tunicamycin, an N-glycosylation inhibitor. Proteomics analysis showed that proteins modified by this induced glycosylation were N-GlcNAc2-modified glycoproteins. Furthermore, CTD110.6 antibodies reacted with N-GlcNAc2-modified glycoproteins produced by a yeast strain with a ts-mutant of ALG1 that could not add a mannos residue to dolichol-PP-GlcNAc2. Our results demonstrated that N-GlcNAc2-modified glycoproteins were induced under glucose deprivation and that they cross-reacted with the O-GlcNAc-specific antibody CTD110.6. We therefore propose that the glycosylation status of proteins previously classified as O-GlcNAc-modified proteins according to their reactivity with CTD110.6 antibodies must be re-examined. We also suggest that the repression of mature N-linked glycoproteins due to increased levels of N-GlcNAc2-modified proteins is a newly recognized pathway for effective use of sugar under stress and deprivation conditions. Further research is needed to clarify the physiological and pathological roles of N-GlcNAc2-modified proteins.

Introduction
We previously screened proteins as tumor markers for bladder cancer by proteomic analysis of cancerous and health tissues and identified some proteins, calreticulin et al, as markers [1–3]. We next attempted to screen for proteins that were key molecules in metastasis and invasiveness by proteomic markers [1–3]. We next attempted to screen for proteins that were key molecules in metastasis and invasiveness by proteomic markers [1–3]. deprivation. Our results demonstrated that N-GlcNAc$_2$-modified glycoproteins were induced under glucose deprivation and that they cross-reacted with the O-GlcNAc-specific antibody CTD110.6.

**Results**

When T24 human bladder cancer cells were subjected to glucose deprivation, the expression of proteins detected by the O-GlcNAc specific antibody CTD110.6 increased more than 5-fold (Figure 1b), as previously reported [9–12]. The expression of basal proteins that reacted with CTD110.6 antibodies in high-glucose medium ($25 \text{ mM glucose}$) decreased $3 \text{ h}$ after glucose deprivation initiated by incubation of the cells in medium with $0 \text{ mM glucose}$, but the signals returned to the original basal levels $6 \text{ h}$ after glucose deprivation was initiated. Expression of the newly induced proteins, which reacted with CTD110.6 antibodies only under glucose deprivation conditions, detected at the $6 \text{ h}$ time point, continued to increase until $24 \text{ h}$ after the treatment, become major part of proteins that reacted with CTD110.6 antibodies $24 \text{ h}$ after the treatment (Figure 1b). These results suggested that two kinds of proteins, the basal proteins and the induced proteins, were produced under glucose deprivation conditions.

We next examined the effects of treating the cells with siRNA specific for OGT and with PUGNAc, an inhibitor of O-GlcNAcase, on expression of proteins that reacted with CTD110.6 antibodies under glucose deprivation (Figure 1c). In the high-glucose medium, expression of the basal proteins increased following treatment with PUGNAc, and the signal clearly decreased following knockdown of OGT with siRNA, as expected. When the cells were incubated in glucose deprivation medium, the responses of basal protein expression levels to treatment with PUGNAc and knockdown with siRNA were similar to the high-glucose medium. However, the induced protein expression levels did not increase following treatment with PUGNAc and their levels did not decrease following siRNA knockdown, unlike the basal proteins. The induced proteins also prevented the reactivity with CTD110.6 antibodies upon addition of $10 \text{ mM GlcNAc}$, like the basal proteins (Figure S1), but they did not react with another O-GlcNAc specific antibody, RL-2, unlike the basal proteins (Figure S2). Then the induced proteins did not react clearly with the Click-It O-GlcNAc detection system, though the basal proteins reacted strongly with this system (Figure S3). These results suggested that the induced proteins differed from the typical O-GlcNAc-modified proteins, which included the basal proteins.

The induced proteins were next analyzed by LC/MS/MS. Six proteins were identified, as shown in Figure 2a and Table S1. Two of the six proteins, Nup88 and HSP70, are common O-GlcNAc-modified proteins [3], and they may constitute some of the basal proteins. The other four proteins (ORP150, Laminin $\beta_3$, Mac2BP, and CD98HC) are glycoproteins with $\alpha$-linked sugars, and they had not been identified previously as O-GlcNAc-modified proteins.

We carried out the validations of the four proteins identified by their reactivity with CTD110.6 antibodies following glucose deprivation of T24 cells by immunoblot (Figure 2b) and immunoprecipitation analysis (Figure 2c). Immunoblot analysis using anti-ORP150 antibodies showed a decrease in the glycosylated form, GRP170, in the high-glucose medium, while levels of the lower molecular weight form, corresponding to non-glycosylated ORP150, increased under glucose deprivation. Immunoblot analysis with anti-Laminin $\beta_3$ antibodies showed that Laminin $\beta_3$ also shifted to the lower molecular weight form in glucose deprivation medium. The bands seen for the lower molecular weight forms of ORP150 and Laminin $\beta_3$ corresponded to the 120 kDa bands previously identified as proteins based on their reaction with CTD110.6 antibodies under glucose deprivation. Immunoblot analysis with anti-CD98HC antibodies showed that glycosylation decreased a decrease in the 70–100 kDa Glycosylated form of CD98HC, while an approximately 55 kDa low molecular weight form was induced by glucose deprivation. Immunoblot analysis with anti-Mac2BP antibodies showed that the 70 and 90 kDa. Glycosylated forms of Mac2BP decreased and the approximately 55 kDa low molecular weight form was induced by glucose deprivation. The bands corresponding to the lower molecular weight forms of CD98HC and Mac2BP also matched the 55 kDa bands previously identified as induced proteins based on their reaction with CTD110.6 antibodies under glucose deprivation. Immunoblot analysis following the time course of glucose deprivation responses showed that the levels of the lower molecular weight forms of the four proteins were clearly increased at $6 \text{ h}$ after the treatment, i.e. at the same time that an increase was previously noted for proteins identified by their reaction with CTD110.6 antibodies (Figure 1b). The immunoprecipitation analysis showed that CTD110.6 antibodies reacted with all four of the lower molecular weight forms that were immunoprecipitated by their specific antibodies, respectively, but not with the mature glycosylated forms. Knockdown of ORP150 with siRNA specifically decreased the expression of the 120 kDa ORP150 protein, which was previously identified using the CTD110.6 antibodies under glucose deprivation (Figure S4). These results demonstrated that the lower molecular weight forms of ORP150, Laminin $\beta_3$, CD98HC, and Mac2BP were induced by glucose deprivation, and that CTD110.6 antibodies also reacted with them under glucose deprivation.

We next examined the effects of tunicamycin, which inhibits N-glycosylation, on expression of the induced proteins (Figure 3a). Tunicamycin treatment increased the expression of basal proteins in high-glucose medium with PUGNAc, as previously described [13]. These results were reasonable, as the pool of UDP-GlcNAc was increased by the inhibition of tunicamycin, so more was available for O-GlcNAcylation. When the cells were incubated in glucose deprivation medium, tunicamycin treatment increased expression of the basal proteins, similar to the response in the high-glucose conditions with PUGNAc. However, expression of the induced proteins disappeared following tunicamycin treatment, unlike the basal proteins. ORP150, Laminin $\beta_3$, CD98HC, and Mac2BP were detected as their naked forms following tunicamycin treatment in both high glucose medium and in glucose deprivation...
The molecular weights of these proteins, as detected by CTD110.6 antibodies following glucose deprivation, were slightly higher than the bands produced following tunicamycin treatment. These tunicamycin effects were observed also in HepG2 (Figure S5) cells and Neuro-2a cells (Figure S6). When the supernatants derived from T24 cells incubated in glucose deprivation medium were treated with Peptide-N-glycosidase F (PNGaseF), which removes all N-glycans from peptides, the bands corresponding to the induced proteins disappeared, although the bands corresponding to the basal proteins did not change (Figure 3c). These results suggested that the induced proteins contained N-linked sugars.

The induced proteins were analyzed by LC/MS/MS in order to further characterize the sugar residues. FLAG-tagged Mac2BP proteins that were over-expressed in 293T cells were concentrated by α-FLAG beads and analyzed by LC/MS/MS, and peptides containing residues modified with GlcNAc2 were found (Figure 3e). The Mac2BP protein sequence contains seven potential N-linked glycosylation sites (N-X-S/T), and N-GlcNAc2 modification was found at five of these sites (Table S2). This result suggested that CTD110.6 antibodies reacted with N-GlcNAc2-modified proteins induced by glucose deprivation.

The existence of N-GlcNAc2-modified proteins has been reported in the yeast ts-mutant K57-6C [14]. This mutant could not add a mannose residue to dolichol-PP-GlcNAc2, as indicated by a loss of ALG1 activity and secretion of N-GlcNAc2-modified exoglucanase following a temperature shift from 25 to 37°C. N-GlcNAc2-modified exoglucanase protein was detected in the yeast culture medium at 37°C by CTD110.6 antibodies (Figure 4a). This signal decreased following tunicamycin treatment of the

doi:10.1371/journal.pone.0018959.g002
37°C culture and it disappeared following PNGaseF treatment of the medium supernatant. These results suggested that CTD110.6 antibodies reacted with the N-GlcNAc2-modified proteins that were induced by the loss of ALG1 activity.

In yeast, the expression of ALG1 is decreased when the carbon source is depleted [15]. However, in T24 cells, the ALG1 band shifted to a slightly higher molecular weight and this shifted band appeared 3 h after glucose deprivation, before the production of N-GlcNAc2-modified proteins was observed (Figure 4b). This suggested that the ALG1 enzyme activity may have been lost. We examined the effects of siRNA specific for ALG1 on the production of N-GlcNAc2-modified proteins (Figure 4c). Under high-glucose medium conditions, the expression of proteins reacted with the O-GlcNAc specific antibody CTD110.6 and the expression of N-GlcNAc2-modified ORP150 hardly increased. However, under glucose deprivation, the expression of proteins reacted with the O-GlcNAc specific antibody CTD110.6 and the expression of N-GlcNAc2-modified proteins under glucose deprivation. The slight effects of siRNA may have been due to a loss of ALG1 enzyme activity caused by modification of ALG1 under glucose deprivation. The partial knock down by siRNA of ALG1 in the high-glucose medium may have caused incomplete inhibition of N-GlcNAc2-modified protein production.

Discussion

The experiments described here clearly indicate that N-GlcNAc2-modified proteins induced under glucose deprivation cross-reacted with the antibody CTD110.6, indicating that this antibody is not actually specific for O-GlcNAc-modified proteins. A schematic summary of all of the experimental results and the hypothesis is presented in Figure 4d. Previous reports have demonstrated the specificity of CTD110.6 antibodies for O-linked derivatives, but their possible specificity for N-linked derivatives containing N-GlcNAc was not evaluated [16]. N-GlcNAc may mimic S/T and thus ‘deceive’ CTD110.6 antibodies as it attaches the second GlcNAc with an O-type linkage. Previous paradoxical reports that glucose deprivation increased protein O-GlcNAcylation in some cancer cells may now be explained by the present study. Our results (Figure 3a, 3b, and Figure S5, S6) suggest that N-GlcNAc2-modified proteins, with which CTD110.6 antibodies reacted under glucose deprivation, are produced by T24 cells as well as by some cancerous cells. Therefore, we proposed that the proteins previously classified as O-GlcNAc-modified proteins according to their reactivity with CTD110.6 antibodies must be re-examined to determine whether they are actually O-GlcNAc- or N-GlcNAc2-modified proteins. The O-GlcNAc specific antibody, RL-2, is not N-GlcNAc2-modified proteins (Figure S2), so RL-2 antibodies may be more specific for O-GlcNAc-modified proteins than CTD110.6 antibodies. Our work has demonstrated that production of N-GlcNAc2-modified proteins will be induced by inhibiting the addition of a mannose residue to dolichol-PP-GlcNAc2 using the yeast Alg1 ts-mutant. In nature, Plasmodium falciparum lacks the Alg1 gene and produces N-GlcNAc2-modified proteins [17]. Congenital Disorders of Glycosylation (CDG) is N-glycosylation disorder induced by mutations in genes in dolichol-linked oligosaccharide biosynthetic pathway [18]. Type Ik patients had mutations of the Alg1 gene and accumulated dolichol-PP-GlcNAc2 [19]. This suggested that these patients produced N-GlcNAc2-modified proteins, similar to the phenomenon observed for the yeast Alg1 ts-mutant. Type Ia, the largest group of CDG patients, had mutations of the Phosphomannomutase 2 (PM2M) gene, which encodes a key enzyme of GDP-mannose synthesis [18]. GDP-mannose is a substrate for ALG1, so inhibition of PM2M enzyme activity will accumulate dolichol-PP-GlcNAc2 and induce N-GlcNAc2-modified proteins. Glucose deprivation will inhibit dolichol-linked oligosaccharide biosynthesis like the defect of CDG patients. Our digital expression analysis for the time course of glucose deprivation by next-generation sequencing showed that the expression level of Serum and Glucocorticoid-regulated kinase (Sgk1), which inhibits PMM2 enzyme activity [20], was up-regulated tenfold by glucose deprivation (data in preparation). This suggests that the synthesis of GDP-mannose was inhibited by glucose deprivation. It is likely that inactivation of both ALG1 and GDP-mannose synthesis was induced under glucose deprivation and that this contributed to the production of N-GlcNAc2-modified proteins. Therefore, N-GlcNAc2-modified proteins may not be produced in high-glucose medium only through inhibition by Alg1 siRNA. The addition of glucosamine under low glucose conditions induced the typical O-GlcNAc-modified proteins but not N-GlcNAc2-modified proteins [9]. An adequate supply of sugars such as glucose and glucosamine will overcome inhibition of GDP-mannose synthesis and will not induce the production of N-GlcNAc2-modified proteins. The production of N-GlcNAc2-modified proteins in T24 and some cancer cell lines may require the deprivation of sugar. We suggest that the repression of mature N-linked glycoproteins due to increased levels of N-GlcNAc2-modified proteins is a newly recognized pathway for effective use of sugar under stress and deprivation conditions. Further research is needed to clarify the physiological and pathological roles of N-GlcNAc2-modified proteins, and the results of these studies will be applicable across a wide range of fields.

Materials and Methods

Cell lines and cell culture conditions

The human bladder cancer cell line, T24 [21] and human embryonic kidney cell line, 293T [22] were usually cultured in the high-glucose version of Dulbecco’s modified Eagle’s medium (DMEM, Nacalai Tesque, Kyoto, Japan), which contained 25 mM glucose and 1 mM sodium pyruvate, supplemented with 10% fetal calf serum (FCS), penicillin [100 U/ml], and streptomycin [100 μg/ml] at 37°C in a humidified 5% CO2 atmosphere. In the experimental culture, cells were seeded in high-glucose medium and then treated with or without transfection of plasmid DNA or small interference RNA (siRNA) at day 1. The culture medium was then replaced on day 2 with fresh high-glucose medium.

medium (25 mM glucose) or with energy deprivation medium, which was depleted of glucose and sodium pyruvate (0 mM glucose, Invitrogen, Carlsbad, CA), and supernatants were collected on day 3. The treatments with PUGNAc (100 μM) and tunicamycin (2 μg/ml) were carried out when the medium was replaced on day 2. \textit{Saccharomyces cerevisiae} strain K57-6C (MATα, alg1-1, ura3-52) was purchased from ATCC. Yeast cells were maintained in YEPD medium. For the production of external exoglucanase, cells were grown in liquid minimal medium supplemented with uracil plus adenine at 26 and 37°C as described [14].

**Plasmids and transfection**

We amplified a human gene for Mac2BP from T24 cells by PCR, using a pair of human Mac2BP-specific primers: MACS1 (5’-AGGGACACGGCCATGACCCCT-3’, nucleotide 170–199) and MACA2 (5’-GTCACACGGTAGGGTGGTC-3’, nucleotide 1914–1993), which corresponded to the nucleotide sequence of the human Mac2BP gene (ENST00000262776). The amplified PCR fragments were cloned into the EcoRI/blunt site of the pCR3.1-FLAG-CT expression vector [23]. The pCR3.1-FLAG-CT vector was constructed by a synthesized FLAG tag cassette introduced into the EcoRI-PstI/blunt sites of the pCR3.1 expression vector, and a stop codon at the C-terminus of the FLAG tag sequence was introduced by this joining. DNA sequencing of the PCR products was performed by the dideoxy chain termination method using an ABI PRISM 3130xl Genetic Analyzer (Applied Biosystems, Foster City, CA, USA). Plasmids were prepared using PureLink HiPure Plasmid DNA Purification Kits (Invitrogen). Transfection of plasmids was carried out in 90-mm dishes using Lipofectamine 2000 (Invitrogen). Cells were transfected with RNA duplexes using DharmaFect (Dharmacon, Inc. Lafayette, CO). The effects of treatment with siRNA specific for Alg1 on the expression of proteins that reacted with CTD110.6 antibodies under glucose deprivation. The left panel shows an immunoblot for CTD110.6, anti-ALG1, anti-ORP150 and anti-α-tubulin antibodies. The right panel shows a quantitative analysis of reactivity with the CTD110.6 antibody and with ALG1 in three experiments, all normalized to the anti-α-tubulin signal for untreated samples in high-glucose medium. A schematic summary of all of the experimental results and the hypothesis.

**Immunoblotting**

Cells were lysed in Laemmli-SDS buffer, subjected to SDS-polyacrylamide gel electrophoresis, and electro-transferred to membranes filters (Immu-no-Blot PVDF membranes, Bio-Rad Laboratories, Richmond, CA). The filters were incubated with a primary antibody in TBS-T (10 mM Tris-HCl, pH 7.6, 0.15 mM sodium chloride, 0.1% Tween20) containing 2% bovine serum albumin (BSA) overnight and incubated for 1 hour in horseradish peroxidase-conjugated anti-mouse, anti-rabbit (GE Healthcare, Buckinghamshire, UK), or anti-mouse IgM (Sigma-Aldrich) diluted 1:5,000 in TBS-T containing 2% BSA. Immunoreactivity was detected using the ECL system (GE Healthcare) with LAS4000 (Fujifilm, Tokyo, Japan) and quantified with Multi gauge (Fujifilm), using an anti-α-tubulin antibody as an internal control. All quantification analyses were performed in triplicate.

**Identification of the proteins by LC/MS/MS analyses**

T24 cells were lysed in Brij lysis buffer containing 20 mM Tris-HCl (pH 7.4), 150 mM NaCl, 1% Brij 98 (Sigma-Aldrich), a protease inhibitor cocktail (Nakalai Tesque), O-GlCNACase inhibitor, O-(2-acetamide-2-deoxy-D-glucopyranosilidene)amino N-phenylcarbamate (PUGNAc; Toronto Research Chemicals, Ontario, Canada), and a phosphatase inhibitor cocktail (Sigma-Aldrich) and were centrifuged for 30 minutes at 10,000 × g at 4°C. The supernatant was incubated with the specific antibody at 4°C for 1 hour. The immunocomplexes were bound to protein-G sepharose for 1 hour at 4°C and washed five times with TBS-T. The proteins bound to the resin were eluted by adding 2 × Laemmli-SDS sample buffer, to a final concentration of 62.5 mM Tris-HCl (pH 6.8), 10% glycerol, 5% 2-mercaptoethanol, 2% sodium dodecyl sulfate (SDS), and 0.01% bromophenol blue, and the samples were boiled for 5 minutes. After centrifugation at 10,000 × g for 2 minutes, the supernatants were analyzed by immunoblotting.

Table S1 Proteins that were induced by glucose deprivation of T24 cells and identified by LC/MS/MS analysis. The probability score, P, is from a new scoring algorithm in BioWorks that is based on the probability that the peptide is a random match to the spectral data. Values of p<0.001 were considered statistically significant. The final score, Sf, indicates how good the protein and peptide match is between the experimental MS/MS data and the theoretical data. The Sf score combines various scores into one final score. Values of Sf >0.40 were considered statistically significant. (TIF)

Table S2 The N-GlcNAc2-peptides from Mac2BP proteins that were induced in T24 cells under glucose deprivation and identified by LC/MS/MS analysis. The probability score, P, is from a new scoring algorithm in BioWorks that is based on the probability that the peptide is a random match to the spectral data. The final score, Sf, indicates how good the protein and peptide match is between the experimental MS/MS data and the theoretical data. The Sf score combines various scores into one final score. Each peptide score was derived using the maximum amount of data available. (TIF)

Acknowledgments

We thank Mr. Noboru Urushiyama (Central Research Laboratory, Shiga University of Medical Science) for assistance in LC/MS/MS. We also thank many fellow researchers of Shiga University of Medical Science and the other institutions for their support and encouragement.
