t-Class semigroups of integral domains

By S. Kabbaj and A. Mimouni at Dhahran

to Marco Fontana on the occasion of his sixtieth birthday

Abstract. The $t$-class semigroup of an integral domain is the semigroup of the isomorphy classes of the $t$-ideals with the operation induced by ideal $t$-multiplication. This paper investigates ring-theoretic properties of an integral domain that reflect reciprocally in the Clifford or Boolean property of its $t$-class semigroup. Contexts (including Lipman and Sally-Vasconcelos stability) that suit best $t$-multiplication are studied in an attempt to generalize well-known developments on class semigroups. We prove that a Pr"ufer $v$-multiplication domain (PVMD) is of Krull type (in the sense of Griffin [24]) if and only if its $t$-class semigroup is Clifford. This extends Bazzoni and Salce’s results on valuation domains [11] and Pr"ufer domains [7, 8, 9, 10].

1. Introduction

The class semigroup of an integral domain $R$, denoted $S(R)$, is the semigroup of nonzero fractional ideals modulo its subsemigroup of nonzero principal ideals [11, 45]. We define the $t$-class semigroup of $R$, denoted $S_t(R)$, to be the semigroup of fractional $t$-ideals modulo its subsemigroup of nonzero principal ideals, that is, the semigroup of the isomorphy classes of the $t$-ideals of $R$ with the operation induced by $t$-multiplication. One may regard $S_t(R)$ as the $t$-analogue of $S(R)$, exactly, as the class group $\text{Cl}(R)$ is the $t$-analogue of the Picard group $\text{Pic}(R)$. We have $\text{Pic}(R) \subseteq \text{Cl}(R) \subseteq S_t(R) \subseteq S(R)$. The first and third containments turn into equality in the class of Pr"ufer domains as the second does so in the class of Krull domains. More details on the $t$-operation are provided in the next section.

A commutative semigroup $S$ is said to be Clifford if every element $x$ of $S$ is (von Neumann) regular, i.e., there exists $a \in S$ such that $x^2a = x$. The importance of a Clifford semigroup $S$ resides in its ability to stand as a disjoint union of subgroups $G_e$, where $e$ ranges over the set of idempotent elements of $S$, and $G_e$ is the largest subgroup of $S$ with identity equal to $e$ (Cf. [30]). The semigroup $S$ is said to be Boolean if for each $x \in S$, $x = x^2$.

Divisibility properties of $R$ are often reflected in group or semigroup-theoretic properties of $\text{Cl}(R)$ or $S(R)$. If $R$ is a Pr"ufer domain, $\text{Cl}(R)$ equals its ideal class group, and then $R$ is a B"ezout domain if and only if $\text{Cl}(R) = 0$. If $R$ is a Krull domain, $\text{Cl}(R)$ equals its usual divisor class group, and then $R$ is a UFD if and only if $\text{Cl}(R) = 0$. So an integral domain $R$ is a UFD if and only if every $t$-ideal of $R$ is principal. Trivially, Dedekind domains (resp., PIDs) have Clifford (resp., Boolean) class semigroup. In 1994, Zanardo and Zannier proved that all orders in quadratic fields have Clifford class semigroup [45]. They also showed that the ring of all entire functions in the complex plane (which is B"ezout) fails to have this property. In 1996, Bazzoni and Salce investigated the structure of $S(V)$ for any arbitrary valuation domain $V$, stating that $S(V)$ is always Clifford [11]. In [7, 8, 9], Bazzoni examined the case of Pr"ufer domains of finite character, showing that these, too, have Clifford class semigroup. In 2001, she completely resolved
the problem for the class of integrally closed domains by proving that “R is an integrally closed domain with Clifford class semigroup if and only if R is a Prüfer domain of finite character” [10], Theorem 4.5. It is worth recalling that, in the series of papers [39, 40, 41], Olberding undertook an extensive study of (Lipman and Sally-Vasconcelos) stability conditions which prepared the ground to address the correlation between stability and the theory of class semigroups.

A domain R is called a PVMD (Prüfer v-multiplication domain) if the v-finite v-ideals form a group under the t-multiplication; equivalently, if R_M is a valuation domain for each t-maximal ideal M of R. Ideal t-multiplication converts ring notions such as PID, Dedekind, Bézout (of finite character), Prüfer (of finite character), and integrality to UFD, Krull, GCD (of finite t-character), PVMD (of finite t-character), and pseudo-integrality, respectively. Recall at this point that the PVMDs of finite t-character (i.e., each proper t-ideal is contained in only finitely many t-maximal ideals) are exactly the Krull-type rings introduced and studied by Griffin in 1967-68 [23, 24]. Also pseudo-integrality (which should be termed t-integrality) was introduced and studied in 1991 by D. F. Anderson, Houston and Zafrullah [4]. We’ll provide more details about this property which turned to be crucial for our study.

This paper examines ring-theoretic properties of an integral domain which reciprocally reflect in semigroup-theoretic properties of its t-class semigroup. Notions and contexts that suit best t-multiplication are studied in an attempt to parallel analogous developments and generalize well-known results on class semigroups. Recall from [10, 32] that an integral domain R is Clifford regular (resp., Boole regular) if S(R) is a Clifford (resp., Boolean) semigroup. A first correlation between regularity and stability conditions can be sought through Lipman stability. Indeed, R is called an L-stable domain if ∪_{n≥1} (I^n : I^n) = (I : I) for every nonzero ideal I of R [1]. Lipman introduced the notion of stability in the specific setting of one-dimensional commutative semi-local Noetherian rings in order to give a characterization of Arf rings; in this context, L-stability coincides with Boole regularity [37]. By analogy, we call an integral domain R Clifford (resp., Boole) t-regular if S_t(R) is a Clifford (resp., Boolean) semigroup. Clearly, a Boole t-regular domain is Clifford t-regular.

Section 2 establishes t-analogues of basic results on t-regularity. We notice that a Krull domain (resp., UFD) is Clifford (resp., Boole) t-regular. These two classes of domains serve as a starting ground for t-regularity (as Dedekind domains and PIDs do for regularity). We show that t-regularity stands as a default measure for some classes of Krull-like domains. For instance, it measures how far a t-almost Dedekind domain [33] is from being a Krull domain or a UFD. In particular, we’ll see that “UFD = Krull + Boole t-regular.” While an integrally closed Clifford regular domain is Prüfer [45], an integrally closed Clifford t-regular domain need not be a PVMD; an example is provided in this regard (Cf. Example 2.8). As a prelude to this, our main theorem of this section (Theorem 2.8) investigates the transfer of t-regularity to pseudo-valuation domains; namely, a PVD R is always Clifford t-regular; moreover, R is Boole t-regular if and only if it is issued from a Boole regular valuation domain.

Section 3 seeks a satisfactory t-analogue for Bazzoni’s theorem on Prüfer domains of finite character [10], Theorem 4.5 (quoted above). From [4], the pseudo-integral closure of a domain R is defined as R = ∪(I_t : I_t), where I ranges over the
S. Kabbaj and A. Mimouni, t-Class semigroups

set of finitely generated ideals of $R$; and $\tilde{R}$ is said to be pseudo-integrally closed if $R = \tilde{R}$. Clearly $R' \subseteq \tilde{R} \subseteq \bar{R}$, where $R'$ and $\bar{R}$ are respectively the integral closure and the complete integral closure of $R$. In view of Example 2.8 (mentioned above), one has to elevate the “integrally closed” assumption in regularity results to “pseudo-integrally closed.” In this vein, we conjecture that “a pseudo-integrally closed domain is Clifford $t$-regular if and only if it is a Krull-type domain.” Our main theorem of this section (Theorem 3.2) asserts that “a PVMD is Clifford $t$-regular if and only if it is a Krull-type domain.” It recovers Bazzoni’s theorem and also reveals the fact that in the class of PVMDs, Clifford $t$-regularity coincides with the finite $t$-character condition. Moreover, we are able to validate the conjecture in a large class of integral domains (Corollary 3.12).

Section 4 is devoted to generating examples. We treat the possible transfer of the PVMD notion endowed with the finite $t$-character condition to pullbacks and polynomial rings. Original families of integral domains with Clifford $t$-class semigroup stem from our results.

All rings considered in this paper are integral domains. For the convenience of the reader, Figure 1 displays a diagram of implications summarizing the relations between the main classes of integrally closed domains that provide a suitable environment for our study. It also places ($t$-)regularity in a ring-theoretic perspective.

![Figure 1. A ring-theoretic perspective for ($t$-)regularity](image-url)
2. Basic results on $t$-regularity

Let $R$ be a domain with quotient field $K$. We first review some terminology related to the $v$- and $t$-operations. For a nonzero fractional ideal $I$ of $R$, let $I^{-1}$ denote $(R : I) = \{ x \in K \mid xI \subseteq R \}$. The $v$- and $t$-closures of $I$ are defined, respectively, by $I_v = (I^{-1})^{-1}$ and $I_t = \cup J \subseteq R$, where $J$ ranges over the set of finitely generated subideals of $I$. The (nonzero) ideal $I$ is said to be divisorial or a $v$-ideal if $I_v = I$, and a $t$-ideal if $I_t = I$. Under the ideal $t$-multiplication $(I,J) \mapsto (IJ)_t$, the set $F_t(R)$ of fractional $t$-ideals of $R$ is a semigroup with unit $R$. An invertible element for this operation is called a $t$-invertible $t$-ideal of $R$. So that the set $Inv_t(R)$ of $t$-invertible $t$-ideals of $R$ is a group with unit $R$. For more basic details about star operations, we refer the reader to [22], Sections 32 and 34. Let $F(R)$, $Inv(R)$, and $P(R)$ denote the sets of nonzero, invertible, and nonzero principal fractional ideals of $R$, respectively. Under this notation, the ($t$-)class groups and semigroups are defined as follows: $Pic(R) = Inv(R)/P(R)$, $Cl(R) = Inv(R)/P(R)$, $\mathcal{S}(R) = F(R)/P(R)$, and $\mathcal{S}_t(R) = F_t(R)/P(R)$.

Recall two basic properties of the $t$-operation which will be used (in different forms) throughout the paper. For any two nonzero ideals $I$ and $J$ of a domain $R$, we have $(IJ)_t = (I,J)_t = (IJ)_t = (IJ)_t$. Also one can easily check that $(I_t : J) = (I_t : J_t)$. In particular, we have $I^{-1} = (R : I) = (R : I_t)$ and, if $I$ is a $t$-ideal, $(I : I^2) = (I : (I^2)_t)$. Actually, these properties hold for any star operation.

Throughout, we shall use $qf(R)$ to denote the quotient field of a domain $R$ and $\overline{T}$ to denote the isomorphy class of an ideal $I$ of $R$ in $\mathcal{S}_t(R)$.

Our first result displays necessary and/or sufficient ideal-theoretic conditions for the isomorphy class of an ideal to be regular in the $t$-class semigroup.

**Lemma 2.1.** Let $I$ be a $t$-ideal of a domain $R$. Then:

1. $\overline{T}$ is regular in $\mathcal{S}_t(R)$ if and only if $I = (I^2(I : I^2))_t$.
2. If $I$ is $t$-invertible, then $\overline{T}$ is regular in $\mathcal{S}_t(R)$.

**Proof.** (1) Assume $\overline{T}$ is regular in $\mathcal{S}_t(R)$. Then there exist a fractional $t$-ideal $J$ of $R$ and $0 \neq c \in qf(R)$ such that $I = c(JI^2)_t = (cJI^2)_t$. We may denote $cJ$ by $J$, that is, $I = (JI^2)_t$. Since $JI^2 \subseteq (JI^2)_t \subseteq I$, $J \subseteq (I : I^2)$. So $I = (JI^2)_t \subseteq (I^2(I : I^2))_t \subseteq I$ and hence $I = (I^2(I : I^2))_t$. The converse is trivial.

(2) Assume $(II^{-1}) = R$. Then $R \subseteq (I : I) \subseteq (II^{-1} : II^{-1}) \subseteq ((II^{-1})_t = (II^{-1})_t = R$. So $I = I^2 = (II^{-1})_t = I^{-1}$. Hence $(I^2(I : I^2))_t = (II^{-1})_t = (II^{-1})_t = I$. By (1), $\overline{T}$ is regular in $\mathcal{S}_t(R)$.

Next, we show that Krull domains (resp., UFDs) are Clifford (resp., Boole) $t$-regular. Further, we identify $t$-regularity as a default condition for some classes of Krull-like domains towards the Krull (or UFD) property. Recall at this point that a domain $R$ is Krull if and only if every $t$-ideal of $R$ is $t$-invertible.

**Proposition 2.2.** (1) Any Krull domain is Clifford $t$-regular.
2. A domain $R$ is a UFD if and only if $R$ is Krull and Boole $t$-regular.
Proof. (1) Follows from Lemma [2.12].

(2) Clearly, a UFD is Boole t-regular. We need only prove the “if” assertion.
Assume $R$ is Krull and Boole t-regular and let $I$ be a t-ideal of $R$. There exists $0 \neq c \in \text{qf}(R)$ such that $(I^2)_t = cI$. Then $(I : I^2) = (I : (I^2)_t) = (I : cI) = c^{-1}(I : I)$. $R$ is completely integrally closed, then $(I : I) = R$, so that $(I : I^2) = (R : I) = I^{-1}$. Therefore $I^{-1} = c^{-1}R$, and hence $I^{-1} = c^{-1}I$. Since $I$ is t-invertible, $R = (I^{-1})_t = (c^{-1}I)_t = c^{-1}I$, hence $I = cR$. It follows that $\text{Cl}(R) = S_t(R) = 0$, i.e., $R$ is a UFD. 

Recall from [33] that a domain $R$ is said to be t-almost Dedekind if $R_M$ is a rank-one DVR for each t-maximal ideal $M$ of $R$. This notion falls strictly between the classes of Krull domains and PVMDs. Our next result shows that t-regularity measures how far a t-almost Dedekind domain or completely integrally closed domain is from being Krull or a UFD. A domain $R$ is said to be strongly t-discrete if it has no t-idempotent t-prime ideals, i.e., for every t-prime ideal $P$ of $R$, $(P^2)_t \subsetneq P$ (Cf. [15]).

**Proposition 2.3.** Let $R$ be a domain. The following statements are equivalent:
(i) $R$ is Krull (resp., a UFD);
(ii) $R$ is t-almost Dedekind and Clifford (resp., Boole) t-regular;
(iii) $R$ is strongly t-discrete, completely integrally closed, and Clifford (resp., Boole) t-regular.

Proof. (i) $\implies$ (ii) Straightforward.

(ii) $\implies$ (i) Suppose there exists a t-ideal $I$ of $R$ which is not t-invertible. Then $J = (I^{-1})_t$ is a proper trace t-ideal of $R$ with $J^{-1} = (J : J)$. Further, $R$ is completely integrally closed since $R = \bigcap R_M$, where $M$ ranges over the t-maximal ideals of $R$. [33], Proposition 2.9. Therefore $J^{-1} = (J : J) = R$, so that $J^2(J : J^2) = J^2((J : J) : J) = J^2J^{-1} = J^2$. Now, $J$ is regular in $S_t(R)$, then $J = (J^2(J : J^2))_t = (J^2)_t$. By induction, we get $J = (J^n)_t$, for each $n \geq 1$. By [33], Proposition 2.54, $J = \bigcap_{n \geq 1} (J^n)_t = (0)$, the desired contradiction.

(i) $\implies$ (iii) Let $P$ be a t-prime ideal of $R$. Since $R$ is Krull, $(PP^{-1})_t = R$. Suppose $P$ is t-idempotent, i.e., $(P^2)_t = P$. Then $((P^2)_tP^{-1})_t = (PP^{-1})_t = R$. Hence $P = ((PP^{-1})P)_t = (P^2P^{-1})_t = (P^2)_t = R$, absurd.

(iii) $\implies$ (i) Suppose there is a t-ideal $I$ of $R$ such that $J = (I^{-1})_t \subsetneq R$. Here too we have $J^{-1} = (J : J) = R$. Let $M$ be a t-maximal ideal of $R$ containing $J$. Necessarily, $(M : M) = M^{-1} = R$. Therefore $(M : M^2) = (M : M) = R$. So $M^2(M : M^2)_t = (M^2)_t$ and hence $M$ is t-idempotent, absurd.

The Boolean statements follow readily from the Clifford statements combined with Proposition [2.2], completing the proof. 

Notice that the ring of all entire functions in the complex plane is (Bézout) strongly (t-)discrete [18], Corollary 8.1.6, and completely integrally closed, but it is not (t-)almost Dedekind (since it has an infinite Krull dimension). Also the “strongly t-discrete” assumption in (iii) is not superfluous, since a non-discrete rank-one valuation domain is completely integrally closed and Clifford (t-)regular [11], but it is not Krull.
Proposition 2.4. Let $R$ be an integrally closed domain and $X$ an indeterminate over $R$. Then $R$ is Clifford (resp., Boole) $t$-regular if and only if so is $R[X]$.

Proof. Assume that $R$ is Clifford $t$-regular and let $J$ be a $t$-ideal of $R[X]$ with $I = J \cap R$. If $I \neq 0$, then $I$ is a $t$-ideal of $R$ and hence $J = I[X]$. If $I = (0)$, then $J = fA[X]$ for some $f \in R[X]$ and $A$ a fractional $t$-ideal of $R$. So that $J^2(J : J^2)$ equals $(I^2(I : I^2))[X]$ or $f(A^2(A : A^2))[X]$. In both cases, $(J^2(J : J^2))_t = J$ by Proposition 2.3(1) (which ensures that the $t$-operation is stable under ideal extension). Therefore $J$ is regular in $S = R[X]$. Conversely, if $J$ is a $t$-ideal of $R$, consider the $t$-ideal $I[X]$ of $R[X]$ and apply the same techniques backward. Similar arguments as above lead to the conclusion for the Boolean statement. \[\square\]

The next result establishes the transfer of $t$-regularity to two types of overrings.

Proposition 2.5. Let $R$ be a Clifford (resp., Boole) $t$-regular domain. Then:

1. $R_S$ is Clifford (resp., Boole) $t$-regular, for any multiplicative subset $S$ of $R$.
2. $(I : I_v)$ is Clifford (resp., Boole) $t$-regular, for any nonzero ideal $I$ of $R$.

For the proof, we need the following lemma.

Lemma 2.6. Let $R$ be a domain, $I$ a fractional ideal of $R$, and $S$ a multiplicative subset of $R$. Then $I_t \subseteq (IR_S)_{t_1}$, where $t_1$ denotes the $t$-operation with respect to $R_S$.

Proof. Let $x \in I_t$. Then there exists a finitely generated ideal $A$ of $R$ such that $A \subseteq I$ and $x(R : A) \subseteq R$. Hence $x(R : A)R_S \subseteq (I)S$. Therefore $x(I)S = x((I)S) : (I)S = (I)$. Since $2$ is a $t$-ideal of $R$, it follows that $R_S$ is Clifford (resp., Boole) $t$-regular.

(1) If $J$ is a $t$-ideal of $R_S$, then $I = J \cap R$ is a $t$-ideal of $R$ by Lemma 2.6. Since $R$ is Clifford (resp., Boole) $t$-regular, then $I = (I^2(I : I^2))_t$ (resp., $(I^2)_t = (I)_t$) for some nonzero $c \in qf(R)$. Hence $J = IR_S = (I^2(I : I^2))_tR_S \subseteq ((I^2(I : I^2))_{t_1}) \subseteq (J^2(J : J^2))_{t_1} \subseteq J$ (resp., $cJ = cIR_S = (I^2)_tR_S \subseteq ((I^2)_t)_{t_1} \subseteq J$). Therefore $J = (J^2(J : J^2))_{t_1}$ (resp., $(J^2)_t = cJ$).

(2) Let $I$ be a nonzero ideal of $R$ and set $T = (I_v : I_v)$. Since $T = (I^2)^{-1} = ((I^{-1}(I^{-1}) = (I(-1))_{v : (I^{-1})_{v}}$, without loss of generality, we may assume that $I$ is a trace $v$-ideal of $R$, that is $T = (I^{-1})$. Also denote by $v_1$ and $t_1$ the $v$- and $t$-operations with respect to $T$. Let $J$ be a nonzero ideal of $T$. Then $J$ is a fractional ideal of $R$ and we claim that $J_t \subseteq J_{t_1}$. Indeed, let $x \in J_t$. Then there exists a finitely generated (fractional) ideal $A$ of $R$ such that $A \subseteq J$ and $x(R : A) \subseteq R$. Let $z \in (T : AT)$. Then $zA \subseteq I \subseteq R$, hence $zI \subseteq (R : A)$, whence $zxI \subseteq x(R : A) \subseteq R$ and $xI \subseteq T = T$. Therefore $x(T : AT) \subseteq T$, and hence $x \in ((T) : (AT))_t = (AT)_{t_1} \subseteq J_{t_1}$. Consequently, if $J$ is a $t$-ideal of $T$, then it’s a $t$-ideal of $R$. Since $R$ is Clifford (resp., Boole) $t$-regular, then $J = (J^2(J : J^2))_{t_1} \subseteq (J^2(J : J^2))_{t_1} \subseteq J$ (resp., $cJ = (J^2)_t \subseteq (J^2)_t \subseteq cJ$, since $J^2 \subseteq (J^2)_{t_1} = cJ$, for some nonzero $c \in qf(R) = qf(T)$). Hence $J = (J^2(J : J^2))_{t_1}$ (resp., $(J^2)_t = cJ$) and therefore $T$ is Clifford (resp., Boole) $t$-regular. \[\square\]
We close this section with an investigation of the integrally closed setting. In this vein, recall Zanardo-Zannier’s crucial result that an integrally closed Clifford regular domain is necessarily Prüfer [45]. In [22], we stated an analogue for Boole regularity, that is, an integrally closed Boole regular domain is Bézout. Next, we show that an integrally closed Clifford (or Boole) t-regular domain need not be a PVMD, the natural context for t-regularity. Our family of such examples stems from the following theorem on the inheritance of t-regularity by PVMDs (i.e., pseudo-valuation domains). We refer the reader to [25] for the definition and the main properties of PVMDs.

**Theorem 2.7.** Let R be a PVD. Then:

1. R is Clifford t-regular.
2. R is Boole t-regular if and only if its associated valuation overring is Boole regular.

**Proof.** (1) We may assume that R is not a valuation domain. Proposition 2.6 of [3] characterizes PVMDs in terms of pullbacks. The aforementioned proposition states that R is a PVD if and only if \( R = \phi^{-1}(k) \) for some subfield k of \( K = V/M \), where V is the associated valuation overring of R, M its maximal ideal and \( \phi \) the canonical homomorphism from V onto K. Now, let I be a t-ideal of R. If I is an ideal of V, we are done (since V is Clifford regular). If I is not an ideal of V, then \( I = c\phi^{-1}(W) \), where \( 0 \neq c \in M \) and W is a k-vector space such that \( k \subseteq W \subseteq K \) (Cf. [6], Theorem 2.1(n)). Assume \( k \subseteq W \). Then \( (k : W) = (0) \). Hence \( I^{-1} = (R : I) = (\phi^{-1}(k) : c\phi^{-1}(W)) = c^{-1}\phi^{-1}(k : W) = c^{-1}M \) by Proposition 6. Since R is a PVD which is not a valuation domain, by [27], Proposition 4.3, R is a TV-domain (i.e., the t- and v-operations coincide in R). Hence \( I = I_t = I_v = (R : c^{-1}M) = cM^{-1} = cV \) is an ideal of V, a contradiction. Therefore \( k = W \) and then \( I = cR \) is a principal ideal of R. So \( T \) is regular in \( S_t(R) \), as desired.

(2) Assume that R is Boole t-regular. By Proposition 2.6, \( V = (M : M) = (M_v : M_v) \) is Boole regular (the t-operation on V is trivial). Conversely, assume that V is Boole regular. Similar arguments as above lead to the conclusion. □

Contrast this result with [22], Theorem 5.1, which asserts that a PVD R associated to a valuation (resp., strongly discrete valuation) domain \( (V, M) \) is Clifford (resp., Boole) regular if and only if \( [V/M : R/M] = 2 \).

**Example 2.8.** There exists an integrally closed Boole (hence Clifford) t-regular domain which is not a PVMD. Indeed, let \( k \) be a field and let X and Y be two indeterminates over k. Let \( R = k + M \) be the PVD associated to the rank-one DVR \( V = k(X)[[Y]] = k(X) + M \), where M = YV. Clearly, R is integrally closed and, by Theorem 2.7, R is Boole t-regular. However, R is not a PVMD by [17], Theorem 4.1.

3. Clifford t-regularity

Recall from [24] that a Krull-type domain is a PVMD with finite t-character (i.e., each nonzero nonunit is contained in only finitely many t-maximal ideals). Also a domain R is said to be pseudo-integrally closed if \( R = \overline{R} = \cup(I_t : I_t) \), where \( I \) ranges over the set of finitely generated ideals of R [4]. This section seeks a t-analogue for Bazzoni’s theorem that “an integrally closed domain R is Clifford...
regular if and only if $R$ is a Prüfer domain of finite character” \[10\]. Theorem 4.5. In view of Example 2.8 one has to elevate the “integrally closed” assumption to “pseudo-integrally closed.” Accordingly, we claim the following:

**Conjecture 3.1.** A pseudo-integrally closed domain $R$ is Clifford t-regular if and only if $R$ is a Krull-type domain.

This is still elusively open. Yet, our main result (Theorem 3.2) of this section recovers Bazzoni’s theorem and validates this conjecture in large classes of (pseudo-integrally closed) domains.

**Theorem 3.2.** A PVMD is Clifford t-regular if and only if it is a Krull-type domain (i.e., in a PVMD, Clifford t-regularity coincides with the finite $t$-character condition).

The proof of the theorem involves several preliminary results, some of which are of independent interest. Experts of $t$-operation may skip the proofs of Lemmas 3.8, 3.9 and 3.10 which are similar in form to their respective analogues for the trivial operation.

The following notation, connected with the $t$-ideal structure of a PVMD, will be of use in the sequel. Assume $R$ is a PVMD and let $I$ be a $t$-ideal of $R$ and $x$ a nonzero nonunit element of $R$. We shall use $\text{Max}_t(R)$ to denote the set of maximal $t$-ideals of $R$. Set $\text{Max}_t(R, I) = \{ M \in \text{Max}_t(R) \mid I \subseteq M \}$, $\text{Max}_t(R, x) = \text{Max}_t(R, xR)$, and $\mathcal{T}_t(R) = \{ M \in \text{Max}_t(R) \mid R_M \nsubseteq \bigcap_{M \in N} R_N, N \in \text{Max}_t(R) \}$. Finally, given $M$ and $N$ two $t$-maximal ideals of $R$, we denote by $M \wedge N$ the largest prime ideal of $R$ contained in $M \cap N$. Note that prime ideals of $R$ contained in a $t$-maximal ideal are necessarily $t$-ideals and form a chain.

**Lemma 3.3.** Let $R$ be a PVMD and $I$ a fractional ideal of $R$. Then for every $t$-prime ideal $P$ of $R$, $I_P R_P = IR_P$.

*Proof.* Here $R_P$ is a valuation domain (where the $t$- and trivial operations coincide), so Lemma 2.6 leads to the conclusion. \(\square\)

**Lemma 3.4.** Let $R$ be a PVMD which is Clifford $t$-regular and $I$ a nonzero fractional ideal of $R$. Then $I$ is $t$-invertible if and only if $I$ is $t$-locally principal.

*Proof.* Suppose $I$ is $t$-locally principal and set $J = (II^1)_t$. Let $M \in \text{Max}_t(R)$. Then $IR_M = aR_M$ for some nonzero $a \in I$. By Lemma 3.3, $I_t : (I_t : I) \subseteq (I_t : I_t : I_t R_M) = (IR_M : IR_M) = (aR_M : aR_M) = R_M$. Therefore $R \subseteq (I_t : I_t) \subseteq \bigcap_{M \in \text{Max}_t(R)} R_M = R$. So $(I_t : I_t^2) = ((I_t : I_t) : I_t) = (R : I_t) = I_t^{-1}$. Since $R$ is Clifford $t$-regular, then $I_t = (I_t^2 (I_t : I_t^2)) = (I_t^2 I_t^{-1})_t = (IJ)_t$. By Lemma 3.3 $aR_M = IR_M = I_t R_M = (I_t) R_M = IJR_M = aJR_M$. It follows that $R_M = JR_M$ for every $M \in \text{Max}_t(R)$, which forces $J$ to equal $R$, as desired.

Conversely, assume that $I$ is $t$-invertible. Then there is a finitely generated ideal $J$ of $R$ such that $J \subseteq I$ and $I_t = J_t$. Hence for each $M \in \text{Max}_t(R)$, $IR_M = I_t R_M = J_t R_M = JR_M = aR_M$ for some $a \in J$, since $R_M$ is a valuation domain. \(\square\)

**Lemma 3.5.** Let $R$ be a PVMD which is Clifford $t$-regular and let $P \subseteq Q$ be two $t$-prime ideals of $R$. Then there exists a finitely generated ideal $I$ of $R$ such that $P \subseteq I_t \subseteq Q$.

*Proof.* Let $x \in Q \setminus P$ and set $J = xR + P$. We claim that $J$ is $t$-invertible. Indeed, let $M$ be a $t$-maximal ideal of $R$. If $J \not\subseteq M$, then $JR_M = R_M$. If $J \subseteq M$, then
Lemma 3.6. Let $R$ be a PVMD which is Clifford $t$-regular and $P$ a $t$-prime ideal of $R$. Then $E(P) = (P : P)$ is a PVMD which is Clifford $t$-regular and $P$ is a $t$-maximal ideal of $E(P)$.

Proof. If $P \in \text{Max}_t(R)$, then $E(P) = R$. We may then assume that $P \notin \text{Max}_t(R)$. By [20], Proposition 1.2 and Lemma 2.4, $E(P) = P^{-1}$ and $P$ is a $t$-prime ideal of $E(P)$. Further $E(P) = P^{-1}$ is $t$-linked over $R$, so $E(P)$ is a PVMD [33]. Let $t_1$ and $v_1$ denote the $t$- and $v$- operations with respect to $E(P)$ and let $J$ be a nonzero fractional ideal of $E(P)$. Clearly $J$ is a fractional ideal of $R$ and we claim that $J_1 \subseteq J_{t_1}$. Indeed, let $x \in J_1$. Then there is a finitely generated subideal $I$ of $J$ such that $x \in I$. So $xI^{-1} \subseteq R$. Let $z \in (E(P) : IE(P)) = (P^{-1} : IP^{-1})$. Then $zIP^{-1} \subseteq P^{-1}$. So $zIP \subseteq P \subseteq R$. Then $zP \subseteq I^{-1}$. So $xzP \subseteq xI^{-1} \subseteq R$. Hence $xz \in P^{-1} = E(P)$. So $x(E(P) : IE(P)) \subseteq E(P)$ and therefore $x \in (IE(P))_{t_1} \subseteq J_{t_1}$. Now, let $J$ be a $t$-ideal of $E(P)$. By the above claim $J$ is a $t$-ideal of $R$. Since $R$ is Clifford $t$-regular, then $J = (J^2(J : J^2))_{t_1} \subseteq (J^2(J : J^2))_{t_1} \subseteq J$ and therefore $J = (J^2(J : J^2))_{t_1}$. It follows that $E(P)$ is Clifford $t$-regular. To complete the proof, we need to show that $P$ is a $t$-maximal ideal of $E(P)$. Deny. Then there is a $t$-maximal ideal $Q$ of $E(P)$ such that $P \subseteq Q$. By Lemma 3.5 there is a finitely generated ideal $J$ of $E(P)$ such that $P \subseteq J_{t_1} \subseteq Q$. On the other hand, since $P$ is a non-$t$-maximal $t$-prime ideal of $E(P)$, by [20], Proposition 1.2, $(E(P) : P) = (P : P) = E(P)$. It follows that $E(P) = P_{v_1} \subseteq (J_{t_1})_{v_1} = J_{v_1} = J_{t_1} \subseteq Q$, the desired contradiction.

Lemma 3.7. Let $R$ be a PVMD which is Clifford $t$-regular and $Q$ a $t$-prime ideal of $R$. Suppose there is a nonzero prime ideal $P$ of $R$ such that $P \subseteq Q$ and $\text{ht}(Q/P) = 1$. Then there exists a finitely generated subideal $I$ of $Q$ such that $\text{Max}_t(R, I) = \text{Max}_t(R, Q)$.

Proof. By [33], Corollary 2.47, $P$ is a $t$-prime ideal of $R$. By [20], Proposition 1.2 and Lemma 2.4, $E(P) = P^{-1}$ and $P$ is a $t$-prime ideal of $E(P)$. Therefore $E(Q) = (Q : Q) \subseteq Q^{-1} \subseteq P^{-1} = E(P)$, and hence $P$ is a prime ideal of $E(Q)$. By Lemma 3.6 $E(Q)$ is a PVMD which is Clifford $t$-regular and $Q$ is a $t$-maximal ideal of $E(Q)$. Thus $P$ is a $t$-prime ideal of $E(Q)$. By Lemma 3.5 there is a finitely generated subideal $J = \sum_{1 \leq i \leq n} a_i E(Q)$ of $Q$ such that $P \subseteq J_{t_1} \subseteq Q$. We claim that $\text{Max}_t(E(Q), J) = \{Q\}$. Indeed, if there is a $t$-maximal ideal $N$ of $E(Q)$ such that $J \subseteq N$, then $P \subseteq J_{t_1} \subseteq N$. So $P \subseteq J_{t_1} \subseteq Q \cap N \subseteq Q$, a contradiction since $\text{ht}(Q/P) = 1$. Now set $I = \sum_{1 \leq i \leq n} a_i R$. Clearly $I \subseteq Q$ and $IE(Q) = J$. We claim that $\text{Max}_t(R, I) = \text{Max}_t(R, Q)$. Let $N \in \text{Max}_t(R, I)$. If $Q \not\subseteq N$, then $R \subseteq E(Q) \subseteq R_N$. Hence $E(Q)_{R_N} = R_N$. So $R_N$ is $t$-linked over $E(Q)$. Since $R_N$ is a valuation domain, then $NR_N$ is a $t$-prime ideal of $R_N$. Hence $M = NR_N \cap E(Q)$ is a $t$-prime ideal of $E(Q)$. Since $I \subseteq N$, then $I \subseteq M$. Hence $J = IE(Q) \subseteq M$. Necessarily $M \subseteq Q$ since $\text{Max}_t(E(Q), J) = \{Q\}$. So $N = NR_N \cap R = NR_N \cap E(Q) \cap R = M \cap R \subseteq Q \cap R = Q$, which is absurd. Hence $Q \subseteq N$ and therefore $\text{Max}_t(R, I) \subseteq \text{Max}_t(R, Q)$. The reverse inclusion is trivial.
Lemma 3.8. Let $R$ be a PVMD which is Clifford $t$-regular and $M$ a $t$-maximal ideal of $R$. If $M \in \mathcal{T}_t(R)$, then there exists a finitely generated subideal $I$ of $M$ with $\text{Max}_t(R, I) = \{M\}$.

Proof. Assume that $M \in \mathcal{T}_t(R)$. Let $x \in (\bigcap_{M \neq N \in \text{Max}_i(R)} R_N) \setminus R_M$. Since $R_M$ is a valuation domain, then $x^{-1} \in MR_M$. Set $I = x^{-1}R \cap R$. We claim that $I$ is $t$-invertible. By Lemma 3.4, it suffices to check that $I$ is $t$-locally principal. Let $Q$ be a $t$-maximal ideal of $R$. If $Q \neq M$, then $I \not\subseteq Q$. Indeed, since $Q \neq M$, then $x \in R_Q$. Hence $IR_Q = (x^{-1}R \cap R)R_Q = x^{-1}R_Q \cap R_Q = R_Q$. So $I \not\subseteq Q$. Then $M$ is the unique $t$-maximal ideal of $R$ that contains $I$ and $IR_M = x^{-1}RM$, as desired. Hence $I$ is $t$-invertible. So there is a finitely generated subideal $J$ of $I$ such that $I = J$, and clearly $\text{Max}_t(R, J) = \{M\}$. □

Lemma 3.9. Let $R$ be a PVMD which is Clifford $t$-regular. Then every nonzero nonunit element of $R$ belongs to a finite number of $t$-maximal ideals in $\mathcal{T}_t(R)$.

Proof. Let $x$ be a nonzero nonunit element of $R$ and let $\{M_\alpha\}_{\alpha \in \Omega}$ be the set of all $t$-maximal ideals of $\mathcal{T}_t(R)$ that contain $x$. For each $\alpha \in \Omega$, let $A_\alpha$ be a finitely generated subideal of $M_\alpha$ such that $\text{Max}_t(R, A_\alpha) = \{M_\alpha\}$ (Lemma 3.3). Without loss of generality, we may assume that $x \in A_\alpha$ (otherwise, we consider $B_\alpha = xR + A_\alpha$). Let $B = \sum_{\alpha \in \Omega} (A_\alpha)^{-1}$. Clearly, $B^{-1} \subseteq R$, for each $\alpha \in \Omega$. Then $xB \subseteq R$ so that $B$ is a fractional ideal of $R$. We claim that $B$ is $t$-locally principal. Indeed, let $N$ be a $t$-maximal ideal of $R$. We envisage two cases. Case 1: $N \neq M_\alpha$ for each $\alpha \in \Omega$. Since $A_\alpha$ is finitely generated, $(A_\alpha)^{-1}R_N = (A_\alpha R_N)^{-1} = R_N$. So $BR_N = R_N$. Case 2: $N = M_\alpha$ for some $\alpha \in \Omega$. Then $(A_\beta)^{-1}R_N = (A_\beta R_N)^{-1} = R_N$, for each $\beta \neq \alpha$ in $\Omega$. Hence $BR_N = (A_\alpha)^{-1}R_N = (A_\alpha R_N)^{-1} = a^{-1}R_N$ where $A_\alpha R_N = a R_N$ (since $R_N$ is a valuation domain). It follows that $B$ is $t$-invertible (Lemma 3.4) and hence there is a finitely generated subideal $J$ of $B$ such that $J_\alpha = J_1 = J_2 = \ldots$. So $B^{-1} = J^{-1}$. Since $J$ is finitely generated, then there are $a_1, \ldots, a_r$ such that $J \subseteq \sum_{1 \leq i \leq r} (A_\alpha_i)^{-1}$. Therefore $B^{-1} = J^{-1} = (\sum_{1 \leq i \leq r} (A_\alpha_i)^{-1})^{-1} = \bigcap_{1 \leq i \leq r} (A_\alpha_i)^{-1} = \bigcap_{1 \leq i \leq r} (A_\alpha_i)$. Consequently, for each $\alpha \in \Omega$, we have $\cap_{1 \leq i \leq r} (A_\alpha_i) = (A_\alpha_i)^{-1} = (A_\alpha_i)$. So there is $a_\alpha$ such that $(A_\alpha_i) \subseteq M_\alpha$, hence $M_\alpha = M_\alpha$, whence $\alpha = a_i$. Therefore $\Omega = \{a_1, \ldots, a_r\}$, as desired. □

Lemma 3.10. Let $R$ be a PVMD which is Clifford $t$-regular and $M$ a $t$-maximal ideal of $R$. Then $M \in \mathcal{T}_t(R)$ if and only if $M \not\subseteq \bigcup_N M \cap N$ where $N$ ranges over $\text{Max}_t(R) \setminus \{M\}$.

Proof. Let $M \in \mathcal{T}_t(R)$ and let $A = \sum_{1 \leq i \leq r} a_i R$ be a finitely generated subideal of $M$ such that $\text{Max}_t(R, A) = \{M\}$ (Lemma 3.3). Suppose that $M = \bigcup_N M \cap N$, where $N$ ranges over $\text{Max}_t(R) \setminus \{M\}$. Then for each $a_i \in A$, there is a $t$-maximal ideal $N_i \neq M$ such that $a_i \in M \cap N_i$. Since $M \cap N_i = \bigcup_{i = 1, \ldots, r}$ is a chain, let $M \cap N_j$ be the largest one for some $j \in \{1, \ldots, r\}$. So $A \subseteq N_j$ and then $N_j \in \text{Max}_t(R, A) = \{M\}$, absurd.

Conversely, let $x \in M \setminus \bigcup_N M \cap N$. Then, for each $t$-maximal ideal $N \neq M$, $x^{-1} \in R_N$ (since $R_N$ is a valuation domain), hence $x^{-1} \in \bigcap_{M \neq N \in \text{Max}_t(R)} R_N$. Since $x^{-1} \not\in R_M$, then $M \in \mathcal{T}_t(R)$, as desired. □

The following basic facts provide some background to the theorem and will be of use in its proof.
• **Fact 1.** For each ideal $I$ of $R$, we have $I_t = \bigcap_{M \in \Max_t(R)} IR_M$ [33], Theorem 2.9.

• **Fact 2.** Let $R$ be a Prüfer domain, $I$ an ideal of $R$, and $A$ and $B$ $R$-submodules of $qf(R)$. Then $I(A \cap B) = IA \cap IB$ [7], Lemma 2.6.

• **Fact 3.** For a $t$-ideal $I$ of a domain $R$, let $\overline{M}(R, I) = \{ M \in \Max_t(R) | I \not\subseteq M \}$ and $C_t(I) = \bigcap_{M \in \overline{M}(R, I)} R_M$ where $M$ ranges over $\overline{M}(R, I)$. Then $(C_t(I) : I) = C_t(I)$. Indeed, it is clear that $C_t(I) \subseteq (C_t(I) : I)$. Conversely, let $x \in C_t(I)$. For each $M \in \overline{M}(R, I)$, let $a \in I \setminus M$. Since $xI \subseteq C_t(I) \subseteq R_M$, then $xa \in R_M$. So $x = \frac{xa}{a} \in R_M$. Hence $x \in C_t(I)$ and therefore $(C_t(I) : I) = C_t(I)$.

• **Fact 4.** For each $t$-ideal $I$ of a domain $R$ with finite $t$-character, there exists a nonzero finitely generated subideal $J$ of $I$ such that $\Max_t(R, I) = \Max_t(R, J)$. The proof apes that of [7], Lemma 2.13, by replacing “maximal ideals” with “$t$-maximal ideals.”

**Proof of Theorem 3.2.** Assume $R$ is a PVMD which is Clifford $t$-regular and let $0 \neq x \in R$. We must show that $\Max_t(R, x)$ is finite. Suppose by way of contradiction that $\Max_t(R, x)$ is infinite. By Lemma 3.9 there is $M \in \Max_t(R, x) \setminus \overline{T}_t(R)$. By Lemma 3.10 $M = \bigcup_N M \cap N$ where $N$ ranges over $\Max_t(R) \setminus \{ M \}$. Since $R_M$ is a valuation domain, $N$ may range over $\Max_t(R, x)$, so that $\{ P_\alpha \}_{\alpha \in \Omega} = \{ M \cap N : M \neq N \in \Max_t(R, x) \}$ is an infinite totally ordered set. For each $\alpha \in \Omega$, we have $0 \not\subseteq \{ x \} \subseteq P_\alpha = M \cap N_\alpha \subseteq N_\alpha$ for some $N_\alpha \in \Max_t(R, x)$. By [33], Theorem 11, there exist distinct prime ideals $P'_\alpha$ and $Q_\alpha$ such that $0 \not\subseteq P_\alpha \subseteq P'_\alpha \subseteq Q_\alpha \subseteq N_\alpha$ with $\height(Q_\alpha/P'_\alpha) = 1$.

**Claim 1.** For every $\alpha \neq \beta$, $Q_\alpha$ and $Q_\beta$ are incomparable.

We may assume $P_\alpha \not\subseteq P_\beta$. Suppose that $Q_\alpha \subseteq Q_\beta$. Then $Q_\alpha$ and $P_\beta$ are comparable. If $Q_\alpha \subseteq P_\beta$, then $P_\alpha \subseteq Q_\alpha \subseteq M \cap N_\alpha = P_\alpha$, absurd. If $P_\beta \subseteq Q_\alpha$, then $P_\beta \subseteq M \cap N_\alpha = P_\alpha \subseteq P_\beta$, absurd. Now, if $Q_\beta \subseteq Q_\alpha$, then $P_\beta \subseteq M \cap N_\alpha = P_\alpha$, which is absurd too. This proves the claim.

Since $P_\alpha \not\subseteq Q_\alpha$, then $Q_\alpha \not\subseteq M$. For each $\alpha$, let $a_\alpha \in Q_\alpha \setminus M$ and consider the ideal $J_\alpha = P_\alpha + a_\alpha R$.

**Claim 2.** $J_\alpha$ is $t$-invertible.

By Lemma 3.4, it suffices to check that $J_\alpha$ is $t$-locally principal. Let $N$ be a $t$-maximal ideal of $R$. Assume w.l.o.g. that $J_\alpha \subseteq N$. Since $R_N$ is a valuation domain and $a_\alpha \not\in P_\alpha$, then $P_\alpha R_N \not\subseteq a_\alpha R_N$. Hence $J_\alpha R_N = a_\alpha R_N$, as desired. Therefore there is a finitely generated subideal $F_\alpha$ of $J_\alpha$ such that $(F_\alpha)_t = (F_\alpha)_l = (J_\alpha)_t$.

Moreover, by Lemma 3.1, there is a finitely generated subideal $I_\alpha$ of $Q_\alpha$ such that $\Max_t(R, I_\alpha) = \Max_t(R, Q_\alpha)$. Consider the finitely generated ideal given by $A_\alpha = F_\alpha + I_\alpha$. Since $I_\alpha \subseteq A_\alpha \subseteq Q_\alpha$, then $\Max_t(R, A_\alpha) = \Max_t(R, Q_\alpha)$. Finally, let $B = \sum_{\alpha \in \Omega} (A_\alpha)^{-1}$.

**Claim 3.** $B$ is a fractional ideal of $R$ which is $t$-invertible.

Indeed, for each $\alpha$, we have $(x) \subseteq P_\alpha = (P_\alpha)_t \subseteq (J_\alpha)_t = (F_\alpha)_t \subseteq (A_\alpha)_t$. So $x(A_\alpha)^{-1} \subseteq (A_\alpha)_t (A_\alpha)^{-1} = (A_\alpha)_t ((A_\alpha)_t)^{-1} \subseteq R$. Hence $xB \subseteq R$ and therefore $B$ is a fractional ideal of $R$. Now let $N$ be a $t$-maximal ideal of $R$. **Case 1:** $A_\alpha \not\subseteq N$ for each $\alpha \in \Omega$. Since $A_\alpha$ is finitely generated, then $(A_\alpha)^{-1} R_N =$
(A_\alpha R_N)^{-1} = R_N$. Hence $BR_N = R_N$. **Case 2:** $A_\alpha \subseteq N$ for some $\alpha \in \Omega$. Since $\text{Max}_i(R, A_\alpha) = \text{Max}_i(R, Q_\alpha)$, then for each $\beta \neq \alpha, A_\beta \not\subseteq N$. Otherwise, $N \in \text{Max}_i(R, A_\beta) = \text{Max}_i(R, Q_\beta)$. Then $Q_\alpha$ and $Q_\beta$ are comparable since both are included in $N$, absurd by the first claim. Thus $N$ contains exactly one $A_\alpha$. So $BR_N = (A_\alpha)^{-1}R_N = (A_\alpha R_N)^{-1} = a^{-1}R_N$ where $aA_\alpha R_N = aR_N$ since $A_\alpha R_N$ is a finitely generated ideal of the valuation domain $R_N$. It follows that $B$ is $t$-locally principal and therefore $t$-invertible (Lemma 3.4).

Consequently, there is a finitely generated subideal $L$ of $B$ such that $L = L_t = B_t = B_\alpha$. Then exist $\alpha_1, \ldots, \alpha_r$ such that $L \subseteq \bigcap_{1 \leq i \leq r} (A_{\alpha_i})^{-1} \subseteq B$. Therefore $B^{-1} = L^{-1} = \left( \bigcap_{1 \leq i \leq r} (A_{\alpha_i})^{-1} \right)^{-1} = \left( \bigcap_{1 \leq i \leq r} (A_{\alpha_i})_v \right) = \left( \bigcap_{1 \leq i \leq r} (A_{\alpha_i})_t \right)$. Now, let $\alpha \in \Omega \setminus \{ \alpha_1, \ldots, \alpha_r \}$. Then $\bigcap_{1 \leq i \leq r} (A_{\alpha_i})_v = B^{-1} \subseteq (A_{\alpha_t})_v = (A_{\alpha_t})_t \subseteq Q_\alpha \subseteq N_\alpha$. So there is $i \in \{ 1, \ldots, r \}$ such that $(A_{\alpha_i})_t \subseteq N_\alpha$. Hence $N_\alpha \in \text{Max}_i(R, A_{\alpha_i}) = \text{Max}(R, Q_{\alpha_i})$ and then $Q_\alpha \subseteq N_\alpha$. This forces $Q_\alpha$ and $Q_{\alpha}$, to be comparable, the desired contradiction. Thus $\text{Max}_i(R, x)$ is finite.

Next, we prove the converse of the theorem. Assume $R$ is a Krull-type domain. Let $I$ be a $t$-ideal of $R$, $\text{Max}_i(R, I) = \{ M_1, \ldots, M_n \}$ and $J = I^2 : I^3$. We wish to show that $I = J_t$. By Fact 1, it suffices to show that $IR_M = JR_M$ for each $t$-maximal ideal of $R$. Let $M \in \text{Max}_i(R)$ and $J \not\subseteq M$ (since $I^2 \subseteq J$). So $IR_M = JR_M = R_M$. Assume $I \not\subseteq M$. Mutatis Mutandis, we may assume that $M = M_1$. One can easily check via Fact 1 that $(I : I) = (I^2 : I^3) \cap C(I)$. By Fact 3, $(I : I^2) = (\prod_{i=1}^n (1R_M : I^2R_M)) \cap C(I) = (1R_M : I^2R_M) \cap (I^2R_M) \cap C(I)$. Let $A = (IR_{M_1} : I^2R_{M_1})$ and $B = (\prod_{i=2}^n (IR_{M_i} : I^2R_{M_i}))$. We have $JR_{M_1} = I^2R_{M_1}(AR_{M_1} \cap BR_{M_1} \cap C(I)R_{M_1})$. By applying Fact 2 in the valuation domain $R_{M_1}$, we obtain $JR_{M_1} = (I^2R_{M_1}AR_{M_1}) \cap (I^2R_{M_1}BR_{M_1}) \cap (I^2R_{M_1}C(I)R_{M_1})$.

On one hand, $I^2R_{M_1}AR_{M_1} = IR_{M_1}$ since $R_{M_1}$ is Clifford regular [11]. Further, we claim that $I^2R_{M_1}BR_{M_1} \supseteq IR_{M_1}$. Indeed, $I^2R_{M_1}BR_{M_1} = \bigcap_{i=2}^n (I^2R_{M_i})R_{M_1} = \bigcap_{i=2}^n (I^2(1R_M : I^2R_M))R_{M_1} = \bigcap_{i=2}^n (I^2R_M(1R_M : I^2R_M))R_{M_1} = \bigcap_{i=2}^n I^2R_{M_1}R_{M_1} \supseteq IR_{M_1}$, as claimed; the first equality is due to Fact 2 and the last equality holds because $R_{M_1}$ is Clifford regular.

On the other hand, $C(I)R_{M_1}$ is an overring of $R_{M_1}$ and hence $C(I)R_{M_1} = R_P$ for some $t$-prime ideal $P$ of $R$ contained in $M_1$. We claim that $I \not\subseteq P$. Indeed, by Fact 4, there exists a nonzero finitely generated ideal $L$ with $L \subseteq J_t \subseteq I$ and $\text{Max}_i(R, L) = \text{Max}_i(R, J_t) = \text{Max}_i(R, I)$. So $C(I) = C(J) = C(L)$. Since $R$ is integrally closed, $(L : L^2) = ((L : L) : L) = (R : L) = L^{-1}$. Furthermore it is easily seen that $L^{-1} \subseteq C(L)$. So $L^2(L : L^2) \subseteq L^2C(L) = L^2C(I)$. Since $R_{M_1}$ is Clifford regular, we get $LR_{M_1} = L^2R_{M_1}R_{M_1} = L^2(L : L^2)R_{M_1} \subseteq L^2C(I)R_{M_1} = L^2R_P$. It results that $LR_P \subseteq L^2R_P$ and hence $LR_P = L^2R_P$. By [35], Theorem 76, $LR_P = R_P$. Hence $L \not\subseteq P$ and thus $I \not\subseteq P$. This proves our claim.

Now, using the above claims, we obtain $JR_{M_1} = I^2R_{M_1}AR_{M_1} \cap I^2R_{M_1}C(I)R_{M_1} = IR_{M_1} \cap I^2R_P = IR_{M_1} \cap R_P = IR_{M_1}$. Consequently, $I = J_t$, as desired. This completes the proof of the theorem.

Since in a Prüfer domain the $t$-operation coincides with the trivial operation, we recover Bazzoni’s theorem (mentioned above) as a consequence of Theorem 3.2. Recall at this point Zanardo-Zannier’s result that “an integrally closed Clifford regular domain is Prüfer” [44]. Also it is worthwhile noticing that during the proof
of Theorem 3.2 we made use of Bazzoni-Salce result that “a valuation domain is Clifford regular” [11].

**Corollary 3.11** (Bazzoni [10], Theorem 4.5). An integrally closed domain $R$ is Clifford regular if and only if $R$ is a Prüfer domain of finite character.

The next result solves Conjecture 3.1 for the context of strongly $t$-discrete domains.

**Corollary 3.12.** Assume $R$ is a strongly $t$-discrete domain. Then $R$ is a pseudo-integrally closed Clifford $t$-regular domain if and only if $R$ is a Krull-type domain.

**Proof.** In view of Theorem 3.2, we only need to prove the “only if” assertion. Precisely, it remains to show that $R$ is a PVMD. Let $I$ be a finitely generated ideal of $R$. If $I_1 = R$, then $I^{-1} = R$ and therefore $(II^{-1})_t = R$, as desired. Assume that $I_t$ is a proper $t$-ideal of $R$. Suppose by way of contradiction that $I$ is not $t$-invertible. Let $M$ be a $t$-maximal ideal of $R$ containing $J = (II^{-1})_t$. Since $R$ is pseudo-integrally closed, $(I_t : I_t) = R$. Hence $(I_t : (I_t)^2) = ((I_t : I_t) : I_t) = (R : I_t) = I^{-1}$. Further $R$ is Clifford $t$-regular, then $I_t = ((I_t)^2(1 : (I_t)^2)) = (R 1^{-1}) = (IJ)_t$. Therefore $R \subseteq J^{-1} = (J : J) \subseteq (IJ : JJ) \subseteq ((IJ)_t : (IJ)_t) = (I_t : I_t) = R$. Consequently, $J^{-1} = (J : J) = R$. Hence $R \subseteq M^{-1} \subseteq J^{-1} = R$, whence $M^{-1} = (M : M) = R$. So $(M : M^2) = ((M : M) : M) = (R : M) = R$. Since $R$ is Clifford $t$-regular, then $M = (M^2(M : M^2)) = (M^2)_t$, and hence $M$ is $t$-idempotent. This contrasts with the hypothesis that $R$ is strongly $t$-discrete. It follows that $I$ is $t$-invertible and thus $R$ is a PVMD.

4. Examples

This section is motivated by an attempt to generating original families of integral domains with Clifford $t$-class semigroup. Next, we announce our first result of this section. It provides necessary and sufficient conditions for a pullback to inherit the Krull type notion.

**Proposition 4.1.** Let $T$ be an integral domain, $M$ a maximal ideal of $T$, $K$ its residue field, $\phi : T \rightarrow K$ the canonical surjection, and $D$ a proper subring of $K$. Let $R = \phi^{-1}(D)$ be the pullback issued from the following diagram of canonical homomorphisms:

\[
\begin{array}{ccc}
R & \rightarrow & D \\
\downarrow & & \downarrow \\
T & \xrightarrow{\phi} & K = T/M \\
\end{array}
\]

Then $R$ is a Krull-type domain if and only if $D$ is a semilocal Bézout domain with $\text{qf}(D) = K$ and $T$ is a Krull-type domain such that $T_M$ is a valuation domain.

**Proof.** By [17], Theorem 4.1, $R$ is a PVMD if and only if so are $T$ and $D$, $\text{qf}(D) = K$, and $T_M$ is a valuation domain. Now notice that $T = S^{-1}R$, where $S = \phi^{-1}(D \setminus \{0\})$. Moreover, by [33], Corollary 2.47, $P$ is a $t$-prime ideal of $R$ if and only if $PT$ is a $t$-prime ideal of $T$, for every prime ideal $P$ of $R$ saturated with respect to $S$. Also, by [17], Proposition 1.8, $q$ is a $t$-maximal ideal of $D$ if and only if $\phi^{-1}(q)$ is a $t$-maximal ideal of $T$, for every prime ideal $q$ of $D$. Finally, if $A$ is a domain with only a finite number of maximal $t$-ideals, then each maximal ideal of $A$ is a $t$-ideal. Using the above four facts, we can easily see that $R$ has finite $t$-character if and only if $D$ is a semilocal Bézout domain and $T$ has finite $t$-character.
The next result investigates the transfer of the finite $t$-character condition to polynomial rings.

**Proposition 4.2.** Let $R$ be an integrally closed domain and $X$ an indeterminate over $R$. Then $R$ has finite $t$-character if and only if so does $R[X]$.

**Proof.** Assume that $R$ has finite $t$-character and let $f$ be a nonzero nonunit element of $R[X]$ and \{${Q_\alpha}$\}$_{\alpha \in \Omega}$ the set of all $t$-maximal ideals of $R[X]$ containing $f$. Set $\Omega_1 = \{\alpha \in \Omega \mid Q_\alpha \cap R = 0\}$ and $\Omega_2 = \{\alpha \in \Omega \mid q_\alpha = Q_\alpha \cap R \neq 0\}$. Assume $\alpha \in \Omega_1$ and let $K = qf(R)$ and $S = R \setminus \{0\}$. Then $S^{-1}Q_\alpha$ is a maximal ideal of $K[X]$. Further $f$ is not a unit in $K[X]$ since $Q_\alpha \cap R = 0$. Now $K[X]$ is of finite character (since a PID), then $\{S^{-1}Q_\alpha\}_{\alpha \in \Omega_1}$ is finite (and so is $\Omega_1$). Assume $\alpha \in \Omega_2$. By \[33\], Lemma 2.32, $q_\alpha$ is a $t$-prime ideal of $R$ with $Q_\alpha = q_\alpha[X]$. We claim that $q_\alpha$ is $t$-maximal in $R$. Deny. Then $q_\alpha \subset M_\alpha$ for some $M_\alpha \in \text{Max}_t(R)$. So $Q_\alpha = q_\alpha[X] \subset M_\alpha[X]$ and so $M_\alpha[X]$ is a $t$-prime ideal of $R[X]$. Now let $a$ denote the leading coefficient of $f$. Clearly, $0 \neq a \in q_\alpha$ (since $Q_\alpha = q_\alpha[X]$). Therefore $\{\{q_\alpha\}_{\alpha \in \Omega_2}$ is finite (and so is $\Omega_2$) since $R$ has finite $t$-character. Consequently, $\Omega$ is finite, as desired. The converse lies on the fact that the extension of a $t$-maximal ideal of $R$ is $t$-maximal in $R[X]$. \[ \square \]

Notice at this point that (as in Example 2.8) one can build numerous examples of non-PVMD Clifford (or Boole) $t$-regular domains through Propositions 2.4 or 2.5 combined with Theorem 2.7. Next, we provide new families of Clifford $t$-regular domains originating from the class of PVMDs via a combination of Theorems 3.2 and Propositions 1.11 & 1.12.

**Example 4.3.** For each integer $n \geq 2$, there exists a PVMD $R_n$ subject to the following conditions:

1. $\text{dim}(R_n) = n$.
2. $R_n$ is Clifford $t$-regular.
3. $R_n$ is not Clifford regular.
4. $R_n$ is not Krull.

Let $V_0$ be a rank-one valuation domain with $K = qf(V_0)$. Let $V = K + N$ be a rank-one non strongly discrete valuation domain (Cf. \[14\], Remark 6(b)). We take $R_n = V[X_1, \ldots, X_n-1]$. For $n \geq 4$, the classical $D + M$ construction provides more examples. Indeed, consider an increasing sequence of valuation domains $V = V_1 \subset V_2 \subset \ldots \subset V_{n-2}$ such that, for each $i \in \{2, \ldots, n-2\}$, $\text{dim}(V_i) = i$ and $V_i/M_i = V/N = K$, where $M_i$ denotes the maximal ideal of $V_i$. Set $T = V_{n-2}[X]$ and $M = (M_{n-2}, X)$. Therefore $R_n = V_0 + M$ is the desired example.
