Abstract

This work develops central limit theorems for cross-validation and consistent estimators of its asymptotic variance under weak stability conditions on the learning algorithm. Together, these results provide practical, asymptotically-exact confidence intervals for $k$-fold test error and valid, powerful hypothesis tests of whether one learning algorithm has smaller $k$-fold test error than another. These results are also the first of their kind for the popular choice of leave-one-out cross-validation. In our real-data experiments with diverse learning algorithms, the resulting intervals and tests outperform the most popular alternative methods from the literature.

1 Introduction

Cross-validation (CV) [48, 25] is a de facto standard for estimating the test error of a prediction rule. By partitioning a dataset into $k$ equal-sized validation sets, fitting a prediction rule with each validation set held out, evaluating each prediction rule on its corresponding held-out set, and averaging the $k$ error estimates, CV produces an unbiased estimate of the test error with lower variance than a single train-validation split could provide. However, these properties alone are insufficient for high-stakes applications in which the uncertainty of an error estimate impacts decision-making. In predictive cancer prognosis and mortality prediction for instance, scientists and clinicians rely on test error confidence intervals based on CV and other repeated sample splitting estimators to avoid spurious findings and improve reproducibility [41, 44]. Unfortunately, the confidence intervals most often used have no correctness guarantees and can be severely misleading [29]. The difficulty comes from the dependence across the $k$ averaged error estimates: if the estimates were independent, one could derive an asymptotically exact confidence interval for test error using a standard central limit theorem. However, the error estimates are seldom independent, due to the overlap amongst training sets and between different training and validation sets. Thus, new tools are needed to develop valid, informative confidence intervals based on CV.

The same uncertainty considerations are relevant when comparing two machine learning methods: before selecting a prediction rule for deployment, one would like to be confident that its test error is better than a baseline or an available alternative. The standard practice amongst both method developers and consumers is to conduct a formal hypothesis test for a difference in test error between two prediction rules [21, 37, 42, 13, 18]. Unfortunately, the most popular tests from the literature like the cross-validated $t$-test of [21], the repeated train-validation $t$-test of [42], and the $5 \times 2$ CV test of [21] have no correctness guarantees and hence can produce misleading conclusions. The difficulty parallels that of the confidence interval setting: standard tests assume independence and do not appropriately account for the dependencies across CV error estimates. Therefore, new tools are also needed to develop valid, powerful tests for test error improvement based on CV.

Our contributions To meet these needs, we characterize the asymptotic distribution of CV error and develop consistent estimates of its variance under weak stability conditions on the learning al-

∗Equal contribution
algorithm. Together, these results provide practical, asymptotically-exact confidence intervals for test error as well as valid and powerful hypothesis tests of whether one learning algorithm has smaller test error than another. In more detail, we prove in Section 2 that k-fold CV error is asymptotically normal around its test error under an abstract asymptotic linearity condition. We then give in Section 3 two different stability conditions that hold for large classes of learning algorithms and losses and individually imply the asymptotic linearity condition. In Section 4, we propose two estimators of the asymptotic variance of CV and prove them to be consistent under similar stability conditions; our second estimator accommodates any choice of k and appears to be the first consistent variance estimator for leave-one-out CV. To validate our theory in Section 5, we apply our intervals and tests to a diverse collection of classification and regression methods on particle physics and flight delay data and observe consistent improvements in width and power over the most popular alternative methods from the literature.

1.1 Related work

Despite the ubiquity of CV, we are only aware of three prior efforts to characterize the precise distribution of cross-validation error. The cross-validation CLT of Dudoit and van der Laan [22] requires considerably stronger assumptions than our own and is not paired with the consistent estimate of variance needed to construct a valid confidence interval or test. LeDell et al. [35] derive both a CLT and a consistent estimate of variance for CV, but these only apply to the area under the ROC curve (AUC) performance measure. Finally, in very recent work, Austern and Zhou [5] derive a CLT and a consistent estimate of variance for CV under more stringent assumptions than our own. We compare our results with each of these works in detail in Section 3.3. We note also that another work [36] aims to test the difference in test error between two learning algorithms using cross-validation but only proves the validity of their procedure for a single train-validation split rather than for CV.

Many other works have studied the problem of bounding or estimating the variance of the cross-validation error [11, 42, 9, 38, 30, 33, 16, 2, 3], but none have established the consistency of their variance estimators. Among these, Kale et al. [30], Kumar et al. [33], Celisse and Guedj [16] introduce relevant notions of algorithmic stability to which we link our results in Section 3.1.

1.2 Notation

Let $\rightarrow$, $\xrightarrow{p}$, and $\xrightarrow{L^q}$ for $q > 0$, denote convergence in distribution, in probability, and in $L^q$ norm (i.e., $X_n \xrightarrow{L^q} X \iff E[|X_n - X|^q] \rightarrow 0$), respectively. For each $m, n \in \mathbb{N}$ with $m \leq n$, we define the set $[n] \triangleq \{1, \ldots, n\}$ and the vector $m:n \triangleq (m, \ldots, n)$. When considering independent random elements $(X, Y)$, we use $E_X$ and $\text{Var}_X$ to indicate expectation and variance only over $X$, respectively; that is, $E_X[f(X, Y)] = E[f(X, Y) \mid Y]$ and $\text{Var}_X(f(X, Y)) = \text{Var}(f(X, Y) \mid Y)$ for any measurable function $f$. We will refer to the Euclidean norm of a vector as the $l^2$ norm in the context of $l^2$ regularization.

2 A Central Limit Theorem for Cross-validation

In this section, we present a new central limit theorem for k-fold cross-validation. Throughout, any asymptotic statement will take $n \rightarrow \infty$, and while we allow the number of folds $k_n$ to depend on the sample size $n$ (e.g., $k_n = n$ for leave-one-out cross-validation), we will write $k$ in place of $k_n$ to simplify our notation. We will also present our main results assuming that $k$ evenly divides $n$, but we address the indivisible setting in the appendix.

Hereafter, we will refer to a sequence $(Z_i)_{i \geq 1}$ of random datapoints taking values in a set $\mathcal{Z}$. Notably, $(Z_i)_{i \geq 1}$ need not be independent or identically distributed. We let $Z_{1:n}$ designate the first $n$ points, and, for any vector $B$ of indices in $[n]$, we let $Z_B$ denote the subvector of $Z_{1:n}$ corresponding to ordered indices in $B$. We will also refer to train-validation splits $(B, B')$. These are vectors of indices in $[n]$ representing the ordered points assigned to the training set and validation set. As is typical in CV, we will assume that $B$ and $B'$ partition $[n]$, so that every datapoint is either in the training or validation set.

\footnote{We keep track of index order to support asymmetric learning algorithms like stochastic gradient descent.}
Given a scalar loss function \( h_n(Z_i, Z_B) \) and a set of \( k \) train-validation splits \( \{(B_j, B'_j)\}_{j=1}^k \) with validation indices \( \{B'_j\}_{j=1}^k \), partitioning \([n]\) into \( k \) folds, we will use the \( k \)-fold cross-validation error

\[
\hat{R}_n = \frac{1}{n} \sum_{j=1}^k \sum_{i \in B'_j} h_n(Z_i, Z_{B_j})
\]

to draw inferences about the \( k \)-fold test error

\[
R_n = \frac{1}{n} \sum_{j=1}^k \sum_{i \in B'_j} \mathbb{E}[h_n(Z_i, Z_{B_j}) \mid Z_{B_j}]. \tag{2.1}
\]

A prototypical example of \( h_n \) is squared error or 0-1 loss,

\[
h_n(Z_i, Z_B) = (Y_i - \hat{f}(X_i; Z_B))^2 \quad \text{or} \quad h_n(Z_i, Z_B) = \mathbb{1}[Y_i \neq \hat{f}(X_i; Z_B)],
\]

composed with an algorithm for fitting a prediction rule \( \hat{f}(\cdot; Z_B) \) to training data \( Z_B \) and predicting the response value of a test point \( Z_i = (X_i, Y_i) \). In this setting, the \( k \)-fold test error is a standard inferential target \([11, 22, 30, 33, 5]\) and represents the average test error of the \( k \) prediction rules \( \hat{f}(\cdot; Z_{B_j}) \). When comparing the performance of two algorithms in Sections 4 and 5, we will choose \( h_n \) to be the difference between the losses of two prediction rules.

### 2.1 Asymptotic linearity of cross-validation

The key to our central limit theorem is establishing that the \( k \)-fold CV error asymptotically behaves like the \( k \)-fold test error plus an average of functions applied to single datapoints. The following proposition provides a convenient characterization of this asymptotic linearity property.

**Proposition 1** (Asymptotic linearity of \( k \)-fold CV). For any sequence of datapoints \( (Z_i)_{i \geq 1} \),

\[
\frac{\sqrt{n}}{\sigma_n} (\hat{R}_n - R_n) - \frac{1}{\sigma_n \sqrt{n}} \sum_{i=1}^n (\hat{h}_n(Z_i) - \mathbb{E} [\hat{h}_n(Z_i)]) \overset{p}{\to} 0 \quad \text{(resp. } L^q \text{)}
\]

for a function \( \hat{h}_n \) with \( \sigma_n^2 \equiv \frac{1}{n} \text{Var}(\sum_{i=1}^n \hat{h}_n(Z_i)) \) if and only if

\[
\frac{1}{\sigma_n \sqrt{n}} \sum_{j=1}^k \sum_{i \in B'_j} \left( h_n(Z_i, Z_{B_j}) - \mathbb{E}[h_n(Z_i, Z_{B_j}) \mid Z_{B_j}] \right) \overset{p}{\to} 0, \tag{2.2}
\]

where the parenthetical convergence indicates that the same statement holds when both convergences in probability are replaced with convergences in \( L^q \) for the same \( q > 0 \).

Typically, one will choose \( \hat{h}_n(z) = \mathbb{E}[h_n(z, Z_{1:n(1-1/k)})] \) in Proposition 1. With this choice, we see that the difference of differences in (2.2) is small whenever \( h_n(Z_i, Z_{B_j}) \) is close to either its expectation given \( Z_i \) or its expectation given \( Z_{B_j} \), but it need not be close to both. As the asymptotic linearity condition (2.2) is still quite abstract, we devote all of Section 3 to establishing sufficient conditions for (2.2) that are interpretable, broadly applicable, and simple to verify. Proposition 1 follows from a more general asymptotic linearity characterization for repeated sample-splitting estimators proved in Appendix A.

### 2.2 From asymptotic linearity to asymptotic normality

So far, we have assumed nothing about the dependencies amongst the datapoints \( Z_i \). If we additionally assume that the datapoints are i.i.d., the average \( \frac{1}{\sigma_n \sqrt{n}} \sum_{i=1}^n (\hat{h}_n(Z_i) - \mathbb{E} [\hat{h}_n(Z_i)]) \) converges to a standard normal under a mild integrability condition, and we obtain the following central limit theorem for CV.

**Theorem 1** (Asymptotic normality of \( k \)-fold CV with i.i.d. data). Under the notation of Proposition 1, suppose that the datapoints \( (Z_i)_{i \geq 1} \) are i.i.d. copies of a random element \( Z_0 \) and that the sequence of \( (\hat{h}_n(Z_0) - \mathbb{E}[\hat{h}_n(Z_0)])^2/\sigma_n^2 \) with \( \sigma_n^2 = \text{Var}(\hat{h}_n(Z_0)) \) is uniformly integrable. If the asymptotic linearity condition (2.2) holds in probability then

\[
\frac{\sqrt{n}}{\sigma_n} (\hat{R}_n - R_n) \overset{d}{\to} \mathcal{N}(0, 1).
\]
Theorem 1 is a special case of a more general result, proved in Appendix B, that applies when the datapoints are independent but not necessarily identically distributed. A simple sufficient condition for the required uniform integrability is that \( \sup_n \mathbb{E}[|h_n(Z_0) - \mathbb{E}[h_n(Z_0)]|/\sigma_n|^\alpha] < \infty \) for some \( \alpha > 2 \). This holds, for example, whenever \( h_n(Z_0) \) has uniformly bounded \( \alpha \) moments (e.g., the 0-1 loss has all moments uniformly bounded) and does not converge to a degenerate distribution. We now turn our attention to the asymptotic linearity condition.

## 3 Sufficient Conditions for Asymptotic Linearity

In this section, we detail practical sufficient conditions for ensuring the asymptotic linearity condition (2.2).

### 3.1 Asymptotic linearity from loss stability

Our first result relates the asymptotic linearity of CV to a specific notion of algorithmic stability, termed loss stability.

**Definition 1** (Mean-square stability and loss stability). For \( m > 0 \), let \( Z_0, Z_1, \ldots, Z_m \) be i.i.d. test and training points with \( Z_{1:m} \) representing \( Z_1 \) replaced by \( Z_0 \). For any function \( h : Z \times \mathbb{Z}^m \rightarrow \mathbb{R} \), the mean-square stability [30] is defined as

\[
\gamma_{ms}(h) \triangleq \frac{1}{m} \sum_{i=1}^{m} \mathbb{E}[(h(Z_0, Z_{1:m}) - h(Z_0, Z_{1:m}^i))^2]
\]

and the loss stability [33] as \( \gamma_{loss}(h) \triangleq \gamma_{ms}(h') \), where

\[
h'(Z_0, Z_{1:m}) \triangleq h(Z_0, Z_{1:m}) - \mathbb{E}[h(Z_0, Z_{1:m}) | Z_{1:m}].
\]

Kumar et al. [33] introduced loss stability to bound the variance of CV in terms of the variance of a single hold-out set estimate. Here we show that a suitable decay in loss stability is also sufficient for \( L^2 \) asymptotic linearity.

**Theorem 2** (Asymptotic linearity from loss stability). Under the notation of Proposition 1 and Definition 1, suppose that the datapoints \( (Z_i)_{i \geq 1} \) are i.i.d. copies of a random element \( Z_0 \). Then

\[
\mathbb{V}ar\left(\frac{1}{\sqrt{n}} \sum_{j=1}^{k} \sum_{i \in B_j} (h'_n(Z_i, Z_{B_j}) - \mathbb{E}[h'_n(Z_i, Z_{B_j}) | Z_i])\right) \leq \frac{2}{3} n (1 - \frac{1}{k}) \gamma_{loss}(h_n).
\]

Hence the \( L^2 \) asymptotic linearity condition (2.2) holds with \( \hat{h}_n(z) = \mathbb{E}[h_n(z, Z_{1:n}(1 - 1/k))] \) if the loss stability satisfies \( \gamma_{loss}(h_n) = o(\sigma_n^2/n) \).

The proof of Theorem 2 is given in Appendix C. Recall that in a typical learning context, we have \( h_n(Z_0, Z_{1:m}) = \ell(Y_0, f(X_0; Z_{1:m})) \) for a fixed loss \( \ell \), a learned prediction rule \( f(\cdot; Z_{1:m}) \), a test point \( Z_0 = (X_0, Y_0) \), and \( m = n(1 - 1/k) \). When \( f(\cdot; Z_{1:m}) \) converges to an imperfect prediction rule, we will commonly have \( \sigma_n^2 = \mathbb{V}ar[\mathbb{E}[h_n(Z_0, Z_{1:m}) | Z_0]] = \Omega(1) \) so that \( \gamma_{loss}(h_n) = o(1/n) \) loss stability is sufficient. However, Theorem 2 also accommodates the cases of non-convergent \( f(\cdot; Z_{1:m}) \) and of \( f(\cdot; Z_{1:m}) \) converging to a perfect prediction rule, so that \( \sigma_n^2 = o(1) \).

Many learning algorithms are known to enjoy decaying loss stability [14, 24, 28, 16, 4], in part because loss stability is upper-bounded by a variety of algorithmic stability notions studied in the literature. For example, stochastic gradient descent on convex and non-convex objectives [28] and the empirical risk minimization of a strongly convex and Lipschitz objective both have \( O(1/n) \) uniform stability [14], and \( O(1/n) \) uniform stability implies a loss stability of \( O(1/n^2) = o(1/n) \) by [30, Lemma 1] and [33, Lemma 2]. Moreover, ensemble methods like bagging and subbagging preserve the stability of various base algorithms and in some cases even improve it [24]. More generally, for any loss function, loss stability is upper-bounded by mean-square stability [30] and all \( L^q \) stabilities [16] for \( q \geq 2 \). For bounded loss functions such as the 0-1 loss, loss stability is also weaker than hypothesis stability (also called \( L^1 \) stability) [19, 31], weak-hypothesis stability [20], and weak-\( L^1 \) stability [34].

### 3.2 Asymptotic linearity from conditional variance convergence

We can also guarantee asymptotic linearity under weaker moment conditions than Theorem 2 at the expense of stronger requirements on the number of folds \( k \).
Theorem 3 (Asymptotic linearity from conditional variance convergence). Under the notation of Proposition 1, suppose that the datapoints \((Z_i)_{i \geq 1}\) are i.i.d. copies of a random element \(Z_0\). If a function \(h_n\) satisfies

\[
\max(k^{q/2}, k^{1-q/2}) \mathbb{E} \left[ \left( \frac{1}{\sigma_n} \text{Var}_{Z_0} \left( h_n(Z_0, Z_{1:n}(1-1/k)) - \bar{h}_n(Z_0) \right) \right)^{q/2} \right] \to 0
\]

for some \(q \in (0, 2]\), then \(\bar{h}_n\) satisfies the \(L^\gamma\) asymptotic linearity condition (2.2). If a function \(\tilde{h}_n\) satisfies

\[
\mathbb{E} \left[ \min \left( k, \frac{\gamma}{\sigma_n} \sqrt{\text{Var}_{Z_0} \left( h_n(Z_0, Z_{1:n}(1-1/k)) - \bar{h}_n(Z_0) \right)} \right) \right] \to 0.
\]

then \(\tilde{h}_n\) satisfies the in-probability asymptotic linearity condition (2.2).

Remark 1. When \(k = O(1)\), as in 10-fold CV, (3.4) holds if and only if

\[
\frac{1}{\sigma_n} \sqrt{\text{Var}_{Z_0} \left( h_n(Z_0, Z_{1:n}(1-1/k)) - \bar{h}_n(Z_0) \right)} \overset{\mathbb{P}}{\to} 0.
\]

Theorem 3 follows from a more general statement proved in Appendix D. When \(k\) is bounded, as in 10-fold CV, the conditions of Theorem 3 are considerably weaker than those of Theorem 2 (see Appendix E), granting asymptotic linearity whenever the conditional variance converges in probability rather than in \(L^3\). Indeed in Appendix G, we detail a simple learning problem in which the loss stability is finite but Theorems 1 and 3 together provide a valid CLT with convergent variance \(\sigma^2_n\).

### 3.3 Comparison with prior work

Our sufficient conditions for asymptotic normality are significantly less restrictive and more broadly applicable than the three prior distributional characterizations of CV error [22, 35, 5]. In particular, the CLT of Dudoit and van der Laan [22, Thm. 3] assumes a bounded loss function, excludes the popular case of leave-one-out cross-validation, and requires the prediction rule to be loss-consistent for a risk-minimizing prediction rule. Similarly, the CLT of LeDell et al. [35, Thm. 4.1] applies only to AUC loss, requires the prediction rule to be loss-consistent for a deterministic prediction rule, and requires a bounded number of folds.

Moreover, in our notation, the recent CLT of Austern and Zhou [5, Thm. 1] restricts focus to learning algorithms that treat all training points symmetrically, assumes that its variance parameter

\[
\tilde{\sigma}^2_n \triangleq \mathbb{E}[\text{Var}(h_n(Z_0, Z_{1:m}) \mid Z_{1:m})]
\]

converges to a non-zero limit, requires mean-square stability \(\gamma_{ms}(h_n) = o(1/n)\), and places an \(o(1/n^2)\) constraint on the second-order mean-square stability

\[
\mathbb{E}[(h_n(Z_0, Z_{1:m}) - h_n(Z_0, Z_{1:m}^{1,2}))^2] = o(1/n^2),
\]

where \(Z_{1:m}^{1,2}\) represents \(Z_{1:m}\) with \(Z_1, Z_2\) replaced by i.i.d. copies \(Z_1', Z_2'\). Kumar et al. [33] showed that the mean-square stability is always an upper bound for the loss stability required by our Theorem 2, and in Appendices F and G we exhibit two simple learning tasks in which \(\gamma_{loss}(h_n) = O(1/n^2)\) but \(\gamma_{ms}(h_n) = \infty\). Furthermore, when \(k\) is constant, as in 10-fold CV, our conditional variance assumptions in Section 3.2 are weaker still and hold even for algorithms with infinite loss stability (see Appendix G). In addition, our results allow for asymmetric learning algorithms (like stochastic gradient descent), accommodate growing, vanishing, and non-convergent variance parameters \(\sigma^2_n\), and do not require the second-order mean-square stability condition (3.6).

Finally, we note that the asymptotic variance parameter \(\sigma^2_n\) appearing in Theorem 1 is never larger and sometimes smaller than the variance parameter \(\tilde{\sigma}^2_n\) in [5, Thm. 1].

### Proposition 2 (Variance comparison).

Let \(\sigma^2_n = \mathbb{E}[\text{Var}(h_n(Z_0, Z_{1:m}) \mid Z_0)]\) be the variance appearing in Theorem 1, with the choice \(h_n(z) = \mathbb{E}[h_n(z, Z_{1:m})]\), and \(\tilde{\sigma}^2_n = \mathbb{E}[\text{Var}(h_n(Z_0, Z_{1:m}) \mid Z_{1:m})]\) be the variance parameter of [5, Eq. (15)] for \(m = n(1 - 1/k)\). Then

\[
\sigma^2_n \leq \tilde{\sigma}^2_n \leq \sigma^2_n + \frac{\chi^2}{n} \gamma_{loss}(h_n),
\]

and the first inequality is strict whenever \(h(Z_0, Z_{1:m}) - \mathbb{E}[h(Z_0, Z_{1:m}) \mid Z_{1:m}]\) depends on \(Z_{1:m}\).
The proof of Proposition 2 can be found in Appendix H. In Appendix G, we present a simple learning task for which our central limit theorem provably holds with $\sigma_n^2$ converging to a non-zero constant, but the central limit theorem in [5, Eq. (15)] is inapplicable because the variance parameter $\sigma_n^2$ is infinite.

4 Confidence Intervals and Tests for $k$-fold Test Error

A primary application of our central limit theorems is the construction of asymptotically-exact confidence intervals (CIs) for the unknown $k$-fold test error. For example, under the assumptions and notation of Theorem 1, any sample statistic $\tilde{\sigma}$ of the variance parameter (by Theorem 1, any sample statistic $\tilde{\sigma}$ of the variance parameter

$$
C_\alpha = \hat{R}_n \pm q_{1-\alpha/2} \tilde{\sigma}_n / \sqrt{n} \quad \text{satisfying} \quad \lim_{n \to \infty} \mathbb{P}(R_n \in C_\alpha) = 1 - \alpha,
$$

(4.1)

where $q_{1-\alpha/2}$ is the $(1-\alpha/2)$-quantile of a standard normal distribution.

A second, related application of our central limit theorems is testing whether, given a dataset $Z_{1:n}$, a $k$-fold partition $\{B'_j\}_{j=1}^k$, and two algorithms $A_1, A_2$ for fitting prediction rules, $A_2$ has larger $k$-fold test error than $A_1$. In this circumstance, we may define

$$
h_n(z, Z_B) = \ell(Y_0, \hat{f}_1(X_0; Z_B)) - \ell(Y_0, \hat{f}_2(X_0; Z_B))
$$

to be the difference of the loss functions of two prediction rules trained on $Z_B$ and tested on $Z_0 = (X_0, Y_0)$. Our aim is to test whether $A_1$ improves upon $A_2$ on the fold partition, that is to test the null $H_0 : R_n \geq 0$ against the alternative hypothesis $H_1 : R_n < 0$. Under the assumptions and notation of Theorem 1, an asymptotically-exact level-$\alpha$ test is given by

$$
\text{REJECT } H_0 \iff \hat{R}_n < q_\alpha \tilde{\sigma}_n / \sqrt{n}
$$

(4.2)

where $q_\alpha$ is the $\alpha$-quantile of a standard normal distribution and $\tilde{\sigma}_n$ is any variance estimator satisfying relative error consistency, $\tilde{\sigma}_n^2 / \sigma_n^2 \xrightarrow{L^1} 1$. Fortunately, our next theorem describes how to compute such a consistent estimate of $\sigma_n^2$ under weak conditions.

Theorem 4 (Consistent within-fold estimate of asymptotic variance). Under the notation of Theorem 1 with $m = n(1 - 1/k)$, $h_n(z) = \mathbb{E}[h_n(z, Z_{1:m})]$, and $k < n$, define the within-fold variance estimator

$$
\hat{\sigma}_{n,\text{in}}^2 \equiv \frac{1}{k} \sum_{j=1}^{k} \frac{1}{(n/k) - 1} \sum_{i \in B'_j} \left( h_n(Z_i, Z_B) - \frac{1}{k} \sum_{i' \in B'_j} h_n(Z_{i'}, Z_B) \right)^2.
$$

Suppose $(Z_i)_{i \geq 1}$ are i.i.d. copies of a random element $Z_0$. Then $\hat{\sigma}_{n,\text{in}}^2 / \sigma_n^2 \xrightarrow{L^1} 1$ whenever $\gamma_{\text{loss}}(h_n) = o(\sigma_n^2 / n)$ and the sequence of $(\hat{h}_n(Z_0) - \mathbb{E}[\hat{h}_n(Z_0)]) / \sigma_n^2$ is uniformly integrable.

Moreover, $\hat{\sigma}_{n,\text{in}}^2 / \sigma_n^2 \xrightarrow{L^1} 1$ whenever $\mathbb{E}[(\hat{h}_n(Z_0) - \mathbb{E}[\hat{h}_n(Z_0)]) / \sigma_n^4] = o(n)$ and the fourth-moment loss stability $\gamma_4(h_n) \equiv \frac{1}{m} \sum_{i=1}^{m} \mathbb{E}[(h_n(Z_0, Z_{1:m}) - h_n(Z_0, Z_{1:m}^i))^4] = o(\sigma_n^4 / n^2)$. Here, $Z_{1:m}^i$ denotes $Z_{1:m}$ with $Z_i$ replaced by an identically distributed copy independent of $Z_{0:m}$.

Theorem 4 follows from explicit error bounds proved in Appendix I. A first notable take-away is that the same two conditions—loss stability $\gamma_{\text{loss}}(h_n) = o(\sigma_n^2 / n)$ and uniform integrability of the sequence of $(\hat{h}_n(Z_0) - \mathbb{E}[\hat{h}_n(Z_0)]) / \sigma_n^2$—grant both a central-limit theorem for CV (by Theorems 1 and 2) and an $L^1$-consistent estimate of $\sigma_n^2$ (by Theorem 4). Moreover, the $L^2$-consistency bound of Appendix I can be viewed as a strengthening of the consistency result of [5, Prop. 1] which analyzes the same variance estimator under more stringent assumptions. In our notation, to establish $L^2$ consistency, [5, Prop. 1] additionally requires $h_n$ symmetric in its training points, convergence of the variance parameter $\sigma_n^2$ (3.5) to a non-zero constant, control over a fourth-moment analogue of mean-square stability $\gamma_4(h_n) = o(\sigma_n^4 / n^2)$ instead of the smaller fourth-moment loss stability $\gamma_4(h_n)$, and the more restrictive fourth-moment condition $\mathbb{E}[(h_n(Z_0, Z_{1:m}) / \sigma_n^4)] = O(1)$. By Proposition 2, their assumptions further imply that $\sigma_n^2$ converges to a non-zero constant. In contrast,

\footnote{The test (4.2) is equivalent to rejecting when the one-sided interval $(-\infty, \hat{R}_n - q_\alpha \tilde{\sigma}_n / \sqrt{n})$ excludes 0.}

\footnote{The result [5, Prop. 1] also assumes a fourth moment second-order stability condition similar to (3.6), but this appears to not be used in the proof.}
Theorem 4 accommodates growing, vanishing, and non-convergent variance parameters $\sigma_n^2$ and a wider variety of learning procedures and losses.

Since Theorem 4 necessarily excludes the case of leave-one-out CV ($k = n$), we propose a second estimator with consistency guarantees for any $k$ and only slightly stronger stability conditions than Theorem 4 when $k = \Omega(n)$. Notably, Austern and Zhou [5] do not provide a consistent variance estimator for $k = n$, and Dudoit and van der Laan [22] do not establish the consistency of any variance estimator.

**Theorem 5** (Consistent all-pairs estimate of asymptotic variance). Under the notation of Theorem 1 with $m = n(1 - 1/k)$, and $\hat{h}_n(z) = \mathbb{E}[h_n(z, Z_{1:m})]$, define the all-pairs variance estimator

$$\hat{\sigma}_{n,\text{out}}^2 = \frac{1}{k} \sum_{j=1}^k \left( \frac{k}{n} \sum_{i \in B'_j} (\hat{h}_n(Z_i, Z_{B_j}) - \hat{R}_n)^2. \right.$$

If $(Z_i)_{i \geq 1}$ are i.i.d. copies of a random element $Z_0$, then $\hat{\sigma}_{n,\text{out}}^2 / \sigma_n^2 \xrightarrow{L^1} 1$ whenever $\gamma_{\text{losa}}(h_n) = o(\sigma_n^2/n)$, $\gamma_{\text{ms}}(h_n) = o(k\sigma_n^2/n)$, and the sequence of $(\hat{h}_n(Z_0) - \mathbb{E}[\hat{h}_n(Z_0)])^2 / \sigma_n^2$ is uniformly integrable.

Theorem 5 follows from an explicit error bound proved in Appendix J and compared with the $L^1$-consistency result of Theorem 4 differs only in the added requirement $\gamma_{\text{ms}}(h_n) = o(k\sigma_n^2/n)$. This mean-square stability condition is especially mild when $k = \Omega(n)$ (as in the case of leave-one-out CV) and ensures that two training sets differing in only $n/k$ points produce prediction rules with comparable test losses.

Importantly, both $\hat{\sigma}_{n,\text{in}}^2$ and $\hat{\sigma}_{n,\text{out}}^2$ can be computed in $O(n)$ time using just the individual datapoint losses $h_n(Z_i, Z_{B_j})$ outputted by a run of $k$-fold cross-validation. Moreover, when $h_n$ is binary, as in the case of 0-1 loss, one can compute $\hat{\sigma}_{n,\text{out}}^2 = \hat{R}_n(1 - \hat{R}_n)$ in $O(1)$ time given access to the overall cross-validation error $\hat{R}_n$ and $\hat{\sigma}_{n,\text{in}}^2 = \frac{1}{k} \sum_{j=1}^k \hat{R}_{n,j} - \hat{R}_n)^2$ in $O(k)$ time given access to the $k$ average fold errors $\hat{R}_{n,j} = \frac{k}{n} \sum_{i \in B'_j} h_n(Z_i, Z_{B_j})$.

5 Numerical Experiments

In this section, we compare our test error confidence intervals (4.1) and tests for algorithm improvement (4.2) with the most popular alternatives from the literature: the hold-out test described in [5, Eq. (17)] based on a single train-validation split, the cross-validated $t$-test of [21], the repeated train-validation $t$-test of [42] (with and without correction), and the 5 $\times$ 2-fold CV test of [21]. These procedures are commonly used and admit both two-sided CIs and one-sided tests, but, unlike our proposals, none except the hold-out method are known to be valid. We use 90-10 train-validation splits for all tests save 5 $\times$ 2-fold CV and report our results using $\hat{\sigma}_{n,\text{out}}^2$ (as $\hat{\sigma}_{n,\text{in}}^2$ results are nearly identical).

Evaluating the quality of CIs and tests requires knowledge of the target test error. In each experiment, we use points subsampled from a large real dataset to form a surrogate ground-truth estimate of the test error. Then, we evaluate the CIs and tests constructed from 500 training sets of sample sizes $n$ ranging from 700 to 11,000 subsampled from the same dataset. Each mean width estimate is displayed with a $\pm 2$ standard error confidence band. The surrounding confidence bands for the coverage, size, and power estimates are $95\%$ Wilson intervals [50], which are known to provide more accurate coverage for binomial proportions than a $\pm 2$ standard error interval [15]. We use the Higgs dataset of [6, 7] to study the classification error of random forest, neural network, and $\ell^2$-penalized logistic regression classifiers and the Kaggle FlightDelays dataset of [1] to study the mean-squared regression error of random forest, neural network, and ridge regression. In each case, we focus on stable settings of these learning algorithms with sufficiently strong $\ell^2$ regularization for

---

6 We exclude McNemar’s test [39] and the difference-of-proportions test which Dietterich [21] found to be less powerful than 5 $\times$ 2-fold CV and the conservative $Z$-test which Nadeau and Bengio [42] found less powerful and more expensive than corrected repeated train-validation splitting.

7 Generalizing the notion of $k$-fold test error (2.1), we define the target test error for each testing procedure to be the average test error of the learned prediction rules; see Appendix K.2 for more details.
the neural network, logistic, and ridge learners and small depths for the random forest trees. Complete experimental details are available in Appendix K.1, and code replicating all experiments can be found at https://github.com/alexandre-bayle/cvci.

5.1 Confidence intervals for test error

In Appendix L.1, we compare the coverage and width of each procedure’s 95% CI for each of the described algorithms, datasets, and training set sizes. Two representative examples—logistic regression classification and random forest regression—are displayed in Fig. 1. While the repeated train-validation CI significantly undercovers in all cases, all remaining CIs have coverage near the 95% target, even for the smallest training set size of \( n = 700 \). The hold-out CI, while valid, is substantially wider and less informative than the other intervals as it is based on only a single train-validation split. Meanwhile, our CLT-based CI delivers the smallest width (and hence greatest precision) for both learning tasks and every dataset size.

5.2 Testing for improved algorithm performance

For convenience, let us write \( \text{Err}(A_1) < \text{Err}(A_2) \) to signify that the test error of \( A_1 \) is smaller than that of \( A_2 \). In Appendix L.2, for each testing procedure, dataset, and pair of algorithms \((A_1, A_2)\), we display the size and power of level \( \alpha = 0.05 \) one-sided tests (4.2) of \( H_1 : \text{Err}(A_1) < \text{Err}(A_2) \). In each case, we report size estimates for experiments with at least 25 replications under the null and power estimates for experiments with at least 25 replications under the alternative. Here, for representative algorithm pairs, we identify the algorithm \( A_1 \) that more often has smaller test error across our simulations and display both the power of the level \( \alpha = 0.05 \) test of \( H_1 : \text{Err}(A_1) < \text{Err}(A_2) \) and the size of the level \( \alpha = 0.05 \) test of \( H_1 : \text{Err}(A_2) < \text{Err}(A_1) \). Fig. 2 displays these results for \((A_1, A_2) = (\ell^2\text{-regularized logistic regression, neural network})\) classification on the left and \((A_1, A_2) = (\text{random forest, ridge})\) regression on the right. The sizes of all testing procedures are below the nominal level of 0.05, and our test is consistently the most powerful for both classification and regression. The hold-out test, while also valid, is significantly less powerful due to its reliance on a single train-validation split.

\[^8\] All widths in Fig. 1 are displayed with \( \pm 2 \) standard error bars, but some are too small to be visible.
Figure 2: Size when testing $H_1: \text{Err}(A_1) < \text{Err}(A_2)$ (top) and power when testing $H_1: \text{Err}(A_2) < \text{Err}(A_1)$ (bottom) of level-0.05 tests for improved test error (see Section 5.2). **Left:** $A_1 = \ell^2$-regularized logistic regression, $A_2 = \text{neural network classification}$. **Right:** $A_1 = \text{random forest}$, $A_2 = \text{ridge regression}$.

5.3 The importance of stability

To illustrate the impact of algorithmic instability on testing procedures, we additionally compare a less stable neural network (with substantially reduced $\ell^2$ regularization strength) and a less stable random forest regressor (with larger-depth trees). In Fig. 12 in Appendix L.3, we observe that the size of every test save the hold-out test rises above the nominal level. In the case of our test, the cause of this size violation is clear. Fig. 14a in Appendix L.3 demonstrates that the variance of $\sqrt{n} \sigma_n (\hat{R}_n - R_n)$ in Theorem 1 is much larger than 1 for this experiment, and Theorem 2 implies this can only occur when the loss stability $\gamma_{\text{loss}}(h_n)$ is large. Meanwhile, the variance of the same quantity is close to 1 for the original stable settings of the neural network and random forest regressors. We suspect that instability is also the cause of the other tests’ size violations; however, it is difficult to be certain, as these alternative tests have no correctness guarantees.

Interestingly, the same destabilized algorithms produce high-quality confidence intervals and relatively stable $h_n$ in the context of single algorithm assessment (see Figs. 13 and 14b in Appendix L.3), as the variance parameter $\sigma_n^2 = \text{Var}(\bar{h}_n(Z_0))$ is significantly larger for single algorithms. This finding highlights an important feature of our results: it suffices for the loss stability to be negligible relative to the noise level $\sigma_n^2/n$.

5.4 Leave-one-out cross-validation

Leave-one-out cross-validation (LOOCV) is often viewed as prohibitive for large datasets, due to the expense of refitting a prediction rule $n$ times. However, for ridge regression, a well-known shortcut based on the Sherman–Morrison–Woodbury formula allows one to carry out LOOCV exactly in the time required to fit a small number of base ridge regressions (see Appendix K.3 for a derivation of this result). Moreover, recent work shows that, for many learning procedures, LOOCV estimates can be efficiently approximated with only $O(1/n^2)$ error [8, 27, 32, 49] (see also [45, 47, 26] for related guarantees). The $O(1/n^2)$ precision of these inexpensive approximations coupled with the LOOCV consistency of $\hat{\sigma}_{n,\text{out}}^2$ (see Theorem 5) allows us to efficiently construct asymptotically-valid CIs and tests for LOOCV, even when $n$ is large. As a simple demonstration, we construct 95% CIs for ridge regression test error based on our LOOCV CLT and compare their coverage and width with
those of the procedures described in Section 5.1. In Fig. 3, we see that, like the 10-fold CV CLT intervals, the LOOCV intervals provide coverage near the nominal level and widths smaller than the popular alternatives from the literature; in fact, the 10-fold CV CLT curves are obscured by the nearly identical LOOCV CLT curves. Complete experimental details can be found in Appendix K.3.

Figure 3: Test error coverage (left) and width (right) of 95% confidence intervals for ridge regression, including leave-one-out CV intervals (see Section 5.4). The CV CLT curves are obscured by the nearly identical LOOCV CLT curves.

6 Conclusion and Future Work

Our central limit theorems and consistent variance estimators provide new, valid tools for testing algorithm improvement and generating test error intervals under algorithmic stability. An important open question is whether practical valid tests and intervals are also available when our stability conditions are violated. Another promising direction for future work is developing analogous tools for the expected test error $E[R_n]$ instead of the $k$-fold test error $R_n$; Austern and Zhou [5] provide significant progress in this direction, but more work, particularly on variance estimation, is needed.

Acknowledgments

We would like to thank Jianqing Fan, Mykhaylo Shkolnikov, Miklos Racz, and Morgane Austern for helpful discussions.

A Proof of Proposition 1: Asymptotic linearity of $k$-fold CV

We first prove a general asymptotic linearity result for repeated sample-splitting estimators. Given a collection $A_n = \{(B_j, B'_j)\}_{j \in [J]}$ of index vector pairs such that for any pair $(B_j, B'_j)$ in $A_n$, $B_j$ and $B'_j$ are disjoint, and a scalar loss function $\rho_{n,j}(Z_{B'_j}, Z_{B_j})$, define the cross-validation error as

$$\hat{R}_n = \frac{1}{J} \sum_{j=1}^{J} \rho_{n,j}(Z_{B'_j}, Z_{B_j})$$

and the multi-fold test error

$$R_n = \frac{1}{J} \sum_{j=1}^{J} \mathbb{E}[\rho_{n,j}(Z_{B'_j}, Z_{B_j}) | Z_{B_j}]$$.

Note that similarly to the number of folds $k$ in cross-validation, $J$ can depend on the sample size $n$, but we write $J$ in place of $J_n$ to simplify our notation.

**Proposition 3** (Asymptotic linearity of CV). For any sequence of datapoints $(Z_i)_{i \geq 1}$, $\frac{\sqrt{n}}{\sigma_n} (\hat{R}_n - R_n) - \frac{\sqrt{n}}{\sigma_n} \sum_{j=1}^{J} (\rho_{n,j}(Z_{B'_j}) - \mathbb{E}[\rho_{n,j}(Z_{B'_j})]) \xrightarrow{p} (\text{resp. } L^q) 0$

for functions $\tilde{\rho}_{n,1}, \ldots, \tilde{\rho}_{n,J}$ with $\sigma_n^2 \triangleq \frac{1}{J} \text{Var}(\sum_{j=1}^{J} \tilde{\rho}_{n,j}(Z_{B'_j}))$ if and only if

$$\frac{\sqrt{n}}{\sigma_n} \sum_{j=1}^{J} \left( \rho_{n,j}(Z_{B'_j}, Z_{B_j}) - \mathbb{E}[\rho_{n,j}(Z_{B'_j}, Z_{B_j}) | Z_{B_j}] \right) - \left( \tilde{\rho}_{n,j}(Z_{B'_j}) - \mathbb{E}[\tilde{\rho}_{n,j}(Z_{B'_j})] \right) \xrightarrow{p} (\text{resp. } L^q) 0$$

where the parenthetical convergence indicates that the same statement holds when both convergences in probability are replaced with convergences in $L^q$ for the same $q > 0$.

**Proof** For each $(B_j, B'_j) \in A_n$, let

$$L_j = \rho_{n,j}(Z_{B'_j}, Z_{B_j}) - \mathbb{E}[\rho_{n,j}(Z_{B'_j}, Z_{B_j}) | Z_{B_j}] - \left( \tilde{\rho}_{n,j}(Z_{B'_j}) - \mathbb{E}[\tilde{\rho}_{n,j}(Z_{B'_j})] \right).$$

Then

$$\frac{\sqrt{n}}{\sigma_n} (\hat{R}_n - R_n) = \frac{\sqrt{n}}{\sigma_n} \sum_{j=1}^{J} (\rho_{n,j}(Z_{B'_j}, Z_{B_j}) - \mathbb{E}[\rho_{n,j}(Z_{B'_j}, Z_{B_j}) | Z_{B_j}])$$

$$= \frac{\sqrt{n}}{\sigma_n} \sum_{j=1}^{J} L_j + \frac{\sqrt{n}}{\sigma_n} \sum_{j=1}^{J} (\tilde{\rho}_{n,j}(Z_{B'_j}) - \mathbb{E}[\tilde{\rho}_{n,j}(Z_{B'_j})]).$$

The result now follows from the assumption that $\frac{\sqrt{n}}{\sigma_n} \sum_{j=1}^{J} L_j \xrightarrow{p} (\text{resp. } L^q) 0$. \hfill \Box

Proposition 1 now follows directly from Proposition 3 with the choices:

- $A_n = \{(B_\ell, i) : \ell \in [k], i \in B'_\ell\}$,
- for all $j \in [J]$, $\rho_{n,j}(Z_i, Z_{B_j}) = h_n(Z_i, Z_{B_j})$ and $\tilde{\rho}_{n,j}(Z_i) = \bar{h}_n(Z_i)$ for the associated $\ell \in [k]$ and $i \in B'_\ell$.

Note that for these choices, we have $J = |A_n| = \sum_{\ell=1}^{k} |B'_\ell| = n$.

B Proof of Theorem 1: Asymptotic normality of $k$-fold CV with i.i.d. data

Theorem 1 follows from the next more general result, which establishes the asymptotic normality of $k$-fold CV with independent (not necessarily identically distributed) data.

**Theorem 6** (Asymptotic normality of $k$-fold CV with independent data). Under the notation of Proposition 1, suppose that the datapoints $(Z_i)_{i \geq 1}$ are independent. If the triangular array $(\bar{h}_n(Z_i) - \mathbb{E}[\bar{h}_n(Z_i)])_{n,i}$ satisfies Lindeberg’s condition,

$$\forall \varepsilon > 0, \frac{1}{\sigma_n \sqrt{n}} \sum_{i=1}^{n} \mathbb{E} \left[ \left( \bar{h}_n(Z_i) - \mathbb{E}[\bar{h}_n(Z_i)] \right)^2 \mathbb{1}[|\bar{h}_n(Z_i) - \mathbb{E}[\bar{h}_n(Z_i)]| > \varepsilon \sqrt{n}] \right] \rightarrow 0,$$ (B.1)

then...
then
\[
\frac{1}{\sigma_n \sqrt{n}} \sum_{i=1}^{n} \left( \hat{h}_n(Z_i) - E[\hat{h}_n(Z_i)] \right) \xrightarrow{d} \mathcal{N}(0,1).
\]

Additionally, if (2.2) holds in probability, then
\[
\frac{X_n}{\sigma_n} \left( \hat{R}_n - R_n \right) \xrightarrow{d} \mathcal{N}(0,1).
\]

**Proof** By independence of the datapoints \((Z_i)_{i \geq 1}\), \((\hat{h}_n(Z_i))_{n,i}\) are independent, and \(n \sigma^2_n = \text{Var} (\sum_{i=1}^{n} \hat{h}_n(Z_i))\). Under Lindeberg’s condition, we get the first convergence result thanks to Lindeberg’s Central Limit Theorem (see [10, Thm. 27.2]). Additionally, if assumption (2.2) holds, we apply Proposition 1 and Slutsky’s theorem to get the second convergence result.

If the \((Z_i)_{i \geq 1}\) are i.i.d., then \(\sigma^2_n = \frac{1}{n} \text{Var} (\sum_{i=1}^{n} \hat{h}_n(Z_i)) = \text{Var}(\hat{h}_n(Z_0))\), and Lindeberg’s condition (B.1) reduces to
\[
\forall \varepsilon > 0, \frac{1}{\sigma_n} \mathbb{E} \left[ (\hat{h}_n(Z_0) - E[\hat{h}_n(Z_0)])^2 \mathbb{I} \left[ |\hat{h}_n(Z_0) - E[\hat{h}_n(Z_0)]| > \varepsilon \sigma_n \sqrt{n} \right] \right] \to 0.
\]

We will show that this follows from the assumed uniform integrability of the sequence \(X_n = (\hat{h}_n(Z_0) - E[\hat{h}_n(Z_0)])^2 / \sigma^2_n\). Indeed, for any \(\varepsilon > 0\) and all \(n\),
\[
\mathbb{E}[X_n \mathbb{I}[X_n > n\varepsilon^2]] \leq \sup_n \mathbb{E}[X_n \mathbb{I}[X_m > n\varepsilon^2]] \to 0,
\]
as \(n \to \infty\) by the uniform integrability of the sequence of \(X_n\). Theorem 1 therefore follows from Theorem 6.

C Proof of Theorem 2: Asymptotic linearity from loss stability

Theorem 2 will follow from the following more general result.

**Theorem 7** (Asymptotic linearity from loss stability). Under the notation of Appendix A, with \(\{ (B_j, B'_j) \}_{j \in [J]} \) a collection of disjoint index vector pairs where \((B'_j)_{j \in [J]}\) is a pairwise disjoint family, and \(\rho_{n,j}(Z_{B_j}, Z_{B'_j}) \triangleq \frac{1}{|B_j|} \sum_{i \in B_j} h_{n,j}(Z_i, Z_{B'_j})\), suppose that the datapoints \((Z_i)_{i \geq 1}\) are i.i.d. copies of a random element \(Z_0\). Define \(\rho'_{n,j}(Z_{B'_j}, Z_{B_j}) \triangleq \rho_{n,j}(Z_i, Z_{B_j}) - E[\rho_{n,j}(Z_i, Z_{B_j}) | Z_{B'_j}]\) and \(\rho''_{n,j}(Z_{B'_j}, Z_{B_j}) \triangleq \rho'_{n,j}(Z_i, Z_{B_j}) - E[\rho'_{n,j}(Z_i, Z_{B_j}) | Z_i]\). Then
\[
\mathbb{E} \left[ \frac{1}{J} \sum_{j=1}^{J} \rho''_{n,j}(Z_{B'_j}, Z_{B_j}) \right]^2 \leq \frac{1}{J} \left( \sum_{j \neq j'} \sqrt{\gamma_{\text{loss}}(h_{n,j}) \gamma_{\text{loss}}(h_{n,j'})} \right) + \sum_{j=1}^{J} \frac{1}{|B_j|^2} \mathbb{E} \left[ |B_j| \gamma_{\text{loss}}(h_{n,j}) \right].
\]

**Proof**

Define \(h'_{n,j}\) and \(h''_{n,j}\) as:
\[
\begin{align*}
    h'_{n,j}(Z_i, Z_{B_j}) &\triangleq h_{n,j}(Z_i, Z_{B_j}) - E[h_{n,j}(Z_i, Z_{B_j}) | Z_{B_j}], \\
    h''_{n,j}(Z_i, Z_{B_j}) &\triangleq h'_{n,j}(Z_i, Z_{B_j}) - E[h'_{n,j}(Z_i, Z_{B_j}) | Z_i].
\end{align*}
\]

Therefore, we have
\[
\rho'_{n,j}(Z_{B'_j}, Z_{B_j}) = \frac{1}{|B_j|} \sum_{i \in B'_j} h'_{n,j}(Z_i, Z_{B_j}) \quad \text{and} \quad \rho''_{n,j}(Z_{B'_j}, Z_{B_j}) = \frac{1}{|B_j|^2} \sum_{i \in B'_j} h''_{n,j}(Z_i, Z_{B_j}).
\]

Thus
\[
\left( \frac{1}{J} \sum_{j=1}^{J} \rho''_{n,j}(Z_{B'_j}, Z_{B_j}) \right)^2 = \frac{1}{J} \sum_{j=1}^{J} \rho''_{n,j}(Z_{B'_j}, Z_{B_j}) \rho''_{n,j}(Z_{B'_j}, Z_{B_j}) = \frac{1}{J} \sum_{j=1}^{J} \frac{1}{|B_j|} \sum_{i \in B'_j} h''_{n,j}(Z_i, Z_{B_j}) h''_{n,j}(Z_i, Z_{B'_j}).
\]

In what follows, \(Z_{B'_j}^{i} \) is \(Z_{B'_j} \) with \(Z_i\) replaced by \(Z'_i\), an i.i.d. copy of \(Z_0\), independent of \((Z_i)_{i \geq 1}\).

Note that if \(i \notin B'_j\), \(Z_{B'_j}^{i}\) is just \(Z_{B'_j}\). We similarly define \(Z_{B'_j}^{i}\).
If \( j \neq j' \), we have \( \mathbb{E}_Z[\sum_{i\in B_j} \sum_{i'\in B_{j'}} h_{n,j}''(Z_i, Z_{B_j}) h_{n,j'}''(Z_{i'}, Z_{B_{j'}})] = 0 \), because (i) \( h_{n,j}''(Z_i, Z_{B_j}) \) and \( h_{n,j'}''(Z_{i'}, Z_{B_{j'}}) \) are conditionally independent given everything but \( Z_i \), and (ii) \( \mathbb{E}_Z[h_{n,j}''(Z_i, Z_{B_j})] = 0 \).

Similarly, if \( j \neq j' \),

\[
\mathbb{E}_Z[\sum_{i\in B_j} \sum_{i'\in B_{j'}} h_{n,j}''(Z_i, Z_{B_j}) h_{n,j'}''(Z_{i'}, Z_{B_{j'}})] = 0,
\]

\[
\mathbb{E}_Z[\sum_{i\in B_j} \sum_{i'\in B_{j'}} h_{n,j}''(Z_i, Z_{B_j}) h_{n,j'}''(Z_{i'}, Z_{B_{j'}})] = 0.
\]

Therefore, if \( j \neq j' \),

\[
\begin{align*}
\mathbb{E}&\left[ \frac{1}{|B_j'|} \frac{1}{|B_{j'}'|} \sum_{i\in B_j} \sum_{i'\in B_{j'}} h_{n,j}''(Z_i, Z_{B_j}) h_{n,j'}''(Z_{i'}, Z_{B_{j'}}) \right] \\
= & \mathbb{E}\left[ \frac{1}{|B_j'|} \frac{1}{|B_{j'}'|} \sum_{i\in B_j} \sum_{i'\in B_{j'}} \left( (h_{n,j}''(Z_i, Z_{B_j}) - h_{n,j}''(Z_i, Z_{B_{j'}})) \right. \\
& \left. \times (h_{n,j'}''(Z_{i'}, Z_{B_{j'}}) - h_{n,j'}''(Z_{i'}, Z_{B_{j'}})) \right) \right] \\
= & \mathbb{E}\left[ \frac{1}{|B_j'|} \frac{1}{|B_{j'}'|} \sum_{i\in B_j} \sum_{i'\in B_{j'}} \mathbb{E}\left[ (h_{n,j}''(Z_i, Z_{B_j}) - h_{n,j}''(Z_i, Z_{B_{j'}}))^2 \right] \\
& \times \mathbb{E}\left[ (h_{n,j'}''(Z_{i'}, Z_{B_{j'}}) - h_{n,j'}''(Z_{i'}, Z_{B_{j'}}))^2 \right] \right]^{1/2} \\
\leq & \left( \mathbb{E}\left[ \frac{1}{|B_j'|} \frac{1}{|B_{j'}'|} \sum_{i\in B_j} \sum_{i'\in B_{j'}} \mathbb{E}\left[ (h_{n,j}''(Z_i, Z_{B_j}) - h_{n,j}''(Z_i, Z_{B_{j'}}))^2 \right] \\
& \times \mathbb{E}\left[ (h_{n,j'}''(Z_{i'}, Z_{B_{j'}}) - h_{n,j'}''(Z_{i'}, Z_{B_{j'}}))^2 \right] \right] \right)^{1/2} \\
= & \left( \mathbb{E}\left[ \frac{1}{|B_j'|} \frac{1}{|B_{j'}'|} \sum_{i'\in B_{j'}} \mathbb{E}\left[ (h_{n,j}''(Z_{i'}, Z_{B_{j'}}) - h_{n,j}''(Z_{i'}, Z_{B_{j'}}))^2 \right] \\
& \times \mathbb{E}\left[ (h_{n,j'}''(Z_{0}, Z_{B_{j'}}) - h_{n,j'}''(Z_{0}, Z_{B_{j'}}))^2 \right] \right] \right)^{1/2} \\
= & \left( \mathbb{E}\left[ \frac{1}{|B_{j'}'|} \sum_{i'\in B_{j'}} \mathbb{E}\left[ (h_{n,j}''(Z_{i'}, Z_{B_{j'}}) - h_{n,j}''(Z_{i'}, Z_{B_{j'}}))^2 \right] \\
& \times \mathbb{E}\left[ (h_{n,j'}''(Z_{0}, Z_{B_{j'}}) - h_{n,j'}''(Z_{0}, Z_{B_{j'}}))^2 \right] \right] \right)^{1/2} \\
= & \sqrt{\gamma_{n}\gamma_{n'}}(\gamma_{n}\gamma_{n'}) = \sqrt{\gamma_{n}\gamma_{n'}} \gamma_{n}\gamma_{n'} = \sqrt{\gamma_{n}\gamma_{n'}} \gamma_{n}\gamma_{n'},
\end{align*}
\]

where we have applied Cauchy–Schwarz inequality and Jensen’s inequality, used that the datapoints are i.i.d. copies of \( Z_0 \) and applied the definitions of mean-square stability and loss stability.

If \( j = j' \) and \( i \neq i' \), then \( \mathbb{E}_Z[h_{n,j}''(Z_i, Z_{B_j}) h_{n,j'}''(Z_{i'}, Z_{B_{j'}})] = 0 \).

If \( j = j' \) and \( i = i' \), then \( \mathbb{E}[h_{n,j}''(Z_i, Z_{B_j})^2] = \mathbb{E}[\text{Var}(h_{n,j}''(Z_i, Z_{B_j}) \mid Z_i)] \).

We now state a conditional application of a version of the Efron–Stein inequality due to Steele [46].

**Lemma 1** (Conditional Efron–Stein inequality). Suppose that, given \( W \), the random vectors \( X_{1:m} \) and \( X_{1:m}' \) are conditionally independent and identically distributed and that the components of \( X_{1:m} \) are conditionally independent given \( W \). Then, for any suitably measurable function \( f \)

\[
\frac{1}{2} \mathbb{E}[(f(X_{1:m}, W) - f(X_{1:m}', W))^2 \mid W] = \text{Var}(f(X_{1:m}, W) \mid W) \\
\leq \frac{1}{2} \sum_{i=1}^m \mathbb{E}[(f(X_{1:m}, W) - f(X_{1:m}', W))^2 \mid W]
\]

where, for each \( i \in [m] \), \( X_{1:m}'_i \) represents \( X_{1:m} \) with \( X_i \) replaced with \( X_i' \).
Using Lemma 1, we get $\mathbb{E}[\operatorname{Var}(h'_{n,j}(Z_i, Z_{B_j}) \mid Z_i)] \leq \frac{1}{2} |B_j| \gamma_{ms}(h'_{n,j}) = \frac{1}{2} |B_j| \gamma_{loss}(h_{n,j})$.

Combining everything, we get

$$\mathbb{E}[\left(\frac{1}{J} \sum_{j=1}^{J} \rho''_{n,j}(Z_{B'_j}, Z_{B_j})\right)^2] \leq \frac{1}{2} \left( \sum_{j \neq j'} \sqrt{\gamma_{loss}(h_{n,j}) \gamma_{loss}(h_{n,j'})} \right)
\quad + \sum_{j=1}^{J} \frac{1}{|B_j|} |B_j| \gamma_{loss}(h_{n,j}).$$

In the case of $k$-fold cross-validation with equal-sized folds and i.i.d. data, the left-hand side of (C.1) becomes

$$\mathbb{E}[\left(\frac{1}{n} \sum_{j=1}^{k} \sum_{i \in B_j} (h'_{n}(Z_i, Z_{B_j}) - \mathbb{E}[h'_{n}(Z_i, Z_{B_j}) | Z_i])\right)^2] \leq \frac{1}{n} \left( \frac{k}{2}(k-1) \gamma_{loss}(h_{n})^2 + k \frac{k}{n} \frac{1}{k} n \gamma_{loss}(h_{n}) \right) = \frac{3}{2} \left(1 - \frac{1}{k}\right) \gamma_{loss}(h_{n}).$$

Hence,

$$\frac{1}{n} \mathbb{E}[\left(\frac{1}{\sqrt{n}} \sum_{j=1}^{k} \sum_{i \in B_j} (h'_{n}(Z_i, Z_{B_j}) - \mathbb{E}[h'_{n}(Z_i, Z_{B_j}) | Z_i])\right) \mid Z_i) \mid Z_i) \leq \frac{3}{2} \left(1 - \frac{1}{k}\right) \gamma_{loss}(h_{n}).$$

We then note that the asymptotic linearity condition (2.2) in $L^2$-norm with the choice $\tilde{h}_n(z) = \mathbb{E}[h_n(z, Z_{1:n(1-1/k)})]$ can be written as

$$\frac{1}{\sigma_n \sqrt{n}} \sum_{j=1}^{k} \sum_{i \in B_j} (h'_{n}(Z_i, Z_{B_j}) - \mathbb{E}[h'_{n}(Z_i, Z_{B_j}) | Z_i]) \stackrel{L^2}{\to} 0,$$

which is implied by (3.2) when $\gamma_{loss}(h_{n}) = o(\sigma_n^2/n)$. Therefore, Theorem 2 follows from Theorem 7.

\section{Proof of Theorem 3: Asymptotic linearity from conditional variance convergence}

Theorem 3 will follow from the following more general statement.

\textbf{Theorem 8} (Asymptotic linearity from conditional variance convergence). \textit{Under the notation of Proposition 1, suppose that the datapoints $(Z_i)_{i \geq 1}$ are i.i.d. copies of a random element $Z_0$. If a function $h_n$ satisfies

$$\max(k^{-1}, 1) \sum_{j=1}^{k} \mathbb{E}\left[ \left( \frac{|B_j|}{n \sigma_n^2} \operatorname{Var}_{Z_0}(h_n(Z_0, Z_{B_j}) - \tilde{h}_n(Z_0)) \right)^{q/2} \right] \to 0,$$

for some $q \in (0, 2]$, then $h_n$ satisfies the $L^2$ asymptotic linearity condition (2.2). If a function $\tilde{h}_n$ satisfies

$$\sum_{j=1}^{k} \mathbb{E}\left[ \min\left( \frac{1}{|B_j|} \sqrt{\operatorname{Var}_{Z_0}(h_n(Z_0, Z_{B_j}) - \tilde{h}_n(Z_0))} \right) \right] \to 0,$$

then $\tilde{h}_n$ satisfies the in-probability asymptotic linearity condition (2.2).}

\textbf{Proof} In the notation of Proposition 1, for each $j \in [k]$, let

$$L_j = \frac{1}{|B_j|} \sum_{i \in B_j} (h_n(Z_i, Z_{B_j}) - \tilde{h}_n(Z_i)) - \mathbb{E}_{Z_0}[h_n(Z_0, Z_{B_j}) - \tilde{h}_n(Z_0)].$$
We first note that for any non-decreasing concave $\psi$ satisfying the triangle inequality, we have

$$
\mathbb{E} \left[ \psi \left( \frac{1}{\sigma_n \sqrt{n}} \sum_{j=1}^{k} |B_j'| |L_j| \right) \right] \leq \mathbb{E} \left[ \psi \left( \frac{1}{\sigma_n \sqrt{n}} \sum_{j=1}^{k} |B_j'| |L_j| \right) \right] \\
\leq \sum_{j=1}^{k} \mathbb{E} \left[ \psi \left( \frac{1}{\sigma_n \sqrt{n}} |B_j'| |L_j| \right) \right] \\
= \sum_{j=1}^{k} \mathbb{E} \left[ Z_{B_j} \left[ \psi \left( \frac{1}{\sigma_n \sqrt{n}} |B_j'| |L_j| \right) \right] \right] \\
\leq \sum_{j=1}^{k} \mathbb{E} \left[ \psi \left( \frac{1}{\sigma_n \sqrt{n}} |B_j'| |\mathbb{E} Z_{B_j} | L_j| \right) \right] \\
\leq \sum_{j=1}^{k} \mathbb{E} \left[ \psi \left( \frac{1}{\sigma_n \sqrt{n}} |B_j'| \sqrt{\text{Var} Z_{B_j}} (L_j) \right) \right] \\
= \sum_{j=1}^{k} \mathbb{E} \left[ \psi \left( \frac{1}{\sigma_n \sqrt{n}} \sqrt{\text{Var} Z_{B_j} (h_n(Z_0, Z_{B_j}) - \bar{h}_n(Z_0))} \right) \right],
$$

where we have applied the triangle inequality twice, the tower property once, and Jensen’s inequality twice. The advertised $L^q$ result for $q \in (0, 1]$ now follows by taking $\psi(x) = x^q$, and the in-probability result follows by taking $\psi(x) = \min(1, x)$ and invoking the following lemma.

**Lemma 2.** For any sequence of random variables $(X_n)_{n \geq 1}$, $X_n \xrightarrow{p} 0$ if and only if $\mathbb{E}[\psi(|X_n|)] \to 0$, where $\psi(x) = \min(1, x)$.

**Proof** If $X_n \xrightarrow{p} 0$, then as $X_n \xrightarrow{d} 0$ and $\psi$ is bounded and continuous for nonnegative $x$, $\mathbb{E}[\psi(|X_n|)] \to 0$. Now suppose $\mathbb{E}[\psi(|X_n|)] \to 0$. Since $\psi$ is nonnegative and non-decreasing for nonnegative $x$, we have $\mathbb{P}(|X_n| > \epsilon) \leq \mathbb{E}[\psi(|X_n|)]/\psi(\epsilon) \to 0$ for every $\epsilon > 0$ by Markov’s inequality. Hence, $X_n \xrightarrow{p} 0$.

Now fix any $q \in (1, 2]$, and note that as $x \mapsto x^q$ is non-decreasing and convex on the nonnegative reals, we have

$$
\mathbb{E} \left[ \frac{1}{\sigma_n \sqrt{n}} \sum_{j=1}^{k} |B_j'| |L_j| \right]^q \leq \mathbb{E} \left[ \left( \frac{1}{\sigma_n \sqrt{n}} \sum_{j=1}^{k} |B_j'| |L_j| \right)^q \right] \\
\leq \frac{k^q}{k} \sum_{j=1}^{k} \mathbb{E} \left[ \left( \frac{1}{\sigma_n \sqrt{n}} |B_j'| |L_j| \right)^q \right] \\
= k^{q-1} \mathbb{E} \left[ \sum_{j=1}^{k} \mathbb{E} Z_{B_j} \left[ \left( \frac{1}{\sigma_n \sqrt{n}} |B_j'|^2 |L_j| \right)^{q/2} \right] \right] \\
\leq k^{q-1} \mathbb{E} \left[ \sum_{j=1}^{k} \left( \frac{|B_j'|^2}{\sigma_n} \text{Var} Z_{B_j} (L_j) \right)^{q/2} \right] \\
= k^{q-1} \mathbb{E} \left[ \sum_{j=1}^{k} \left( \frac{|B_j'|^2}{\sigma_n} \text{Var} Z_{B_j} (h_n(Z_0, Z_{B_j}) - \bar{h}_n(Z_0)) \right)^{q/2} \right],
$$

where we have applied the triangle inequality, Jensen’s inequality using the convexity of $x \mapsto x^q$, the tower property, and Jensen’s inequality using the concavity of $x \mapsto x^{q/2}$. Hence, the $L^q$ result for $q \in (1, 2]$ follows from our convergence assumption.

Theorem 3 then follows from Theorem 8 by replacing $|B_j'|$ with $\frac{2}{k}$ and $Z_{B_j}$ with $Z_{1:n(1-1/k)}$ since folds are equal-sized and the $Z_i$’s are i.i.d.
E Conditional Variance Convergence from Loss Stability

We show that the quantity appearing in (3.3) is controlled by the loss stability, for any $q \in (0, 2]$. Note however that (3.3) can be satisfied even in a case where the loss stability is infinite (see Appendix G).

**Proposition 4** (Conditional variance convergence from loss stability). Suppose that $k$ divides $n$ evenly. Under the notation of Theorem 3 with $h_n(z) = E[h_n(z, Z; 1:n(1-1/k))]$, 

$$
\mathbb{E} \left[ \left( \frac{1}{\sigma_n^2} \text{Var}_{Z_0} \left( h_n(Z_0, Z; 1:n(1-1/k)) - \tilde{h}_n(Z_0) \right) \right)^{q/2} \right] \leq \left( \frac{1}{\sigma_n^2} \frac{1}{2} n(1-1/k) \gamma_{\text{loss}}(h_n) \right)^{q/2},
$$

for any $q \in (0, 2]$. Consequently, the condition (3.3) is verified whenever $\gamma_{\text{loss}}(h_n) = o\left( \frac{\sigma_n^2}{n(1-1/k) \max(k, k^{1/2/q-1})} \right)$.

**Remark 2.** If $k = O(1)$, this loss stability assumption simplifies to $\gamma_{\text{loss}}(h_n) = o\left( \frac{\sigma_n^2}{n} \right)$ for any $q \in (0, 2]$.

**Proof** Write $m = n(1-1/k)$. Then

$$
\text{Var}_{Z_0}(h_n(Z_0, Z; 1:m) - \mathbb{E}[h_n(Z_0, Z; 1:m) | Z_0]) = \text{Var}_{Z_0}(h'_n(Z_0, Z; 1:m) - \mathbb{E}[h'_n(Z_0, Z; 1:m) | Z_0]),}
$$

since the difference $h_n(Z_0, Z; 1:m) - h'_n(Z_0, Z; 1:m) = \mathbb{E}[h_n(Z_0, Z; 1:m) | Z_1:m]$ is a $Z_1:m$-measurable function. For $0 < q \leq 2$, using Jensen’s inequality,

$$
\mathbb{E} \left[ \left( \text{Var}_{Z_0}(h'_n(Z_0, Z; 1:m) - \mathbb{E}[h'_n(Z_0, Z; 1:m) | Z_0]) \right)^{q/2} \right] \leq \mathbb{E}[\text{Var}_{Z_0}(h'_n(Z_0, Z; 1:m) - \mathbb{E}[h'_n(Z_0, Z; 1:m) | Z_0])^{q/2}].
$$

We can bound it using loss stability.

$$
\text{Var}_{Z_0}(h'_n(Z_0, Z; 1:m) - \mathbb{E}[h'_n(Z_0, Z; 1:m) | Z_0]) = \mathbb{E}_{Z_0} \left[ \left( h'_n(Z_0, Z; 1:m) - \mathbb{E}[h'_n(Z_0, Z; 1:m) | Z_0) \right) - \left( \mathbb{E}[h'_n(Z_0, Z; 1:m) | Z_1:m] - \mathbb{E}[h'_n(Z_0, Z; 1:m)]) \right) \right]^2 = \mathbb{E}[\left( \mathbb{E}[h'_n(Z_0, Z; 1:m) - \mathbb{E}[h'_n(Z_0, Z; 1:m) | Z_0] \right)^2 | Z_1:m],
$$

so that

$$
\mathbb{E}[\text{Var}_{Z_0}(h'_n(Z_0, Z; 1:m) - \mathbb{E}[h'_n(Z_0, Z; 1:m) | Z_0])] = \mathbb{E}[\left[ \mathbb{E}[h'_n(Z_0, Z; 1:m) - \mathbb{E}[h'_n(Z_0, Z; 1:m) | Z_0] \right]^2 | Z_0) = \mathbb{E}[\text{Var}(h'_n(Z_0, Z; 1:m) | Z_0)] \leq \frac{1}{2} m \gamma_{\text{loss}}(h_n),
$$

where the last inequality comes from Lemma 1. Consequently,

$$
\mathbb{E} \left[ \left( \frac{1}{\sigma_n^2} \text{Var}_{Z_0}(h_n(Z_0, Z; 1:m) - \mathbb{E}[h_n(Z_0, Z; 1:m) | Z_0]) \right)^{q/2} \right] \leq \left( \frac{1}{\sigma_n^2} \frac{1}{2} m \gamma_{\text{loss}}(h_n) \right)^{q/2}.
$$

\[ \square \]

F Excess Loss of Sample Mean: $o\left( \frac{\sigma_n^2}{n} \right)$ loss stability, constant $\sigma_n^2 \in (0, \infty)$, infinite mean-square stability

Here we present a very simple learning task in which (i) the CLT conditions of Theorems 1 and 2 hold and (ii) mean-square stability (3.1) is infinite.

**Example 1** (Excess loss of sample mean: $o\left( \frac{\sigma_n^2}{n} \right)$ loss stability, constant $\sigma_n^2 \in (0, \infty)$, infinite mean-square stability). Suppose $(Z_i)_{i \geq 1}$ are independent and identically distributed copies of a random element $Z_0$ with $E[Z_0] = 0$ and $E[Z_0^2] < \infty$. Consider $k$-fold cross-validation of the excess loss of the sample mean relative to a constant prediction rule:

$$
h_n(z, D) = (z - \hat{f}(D))^2 - (z - a)^2 \quad \text{where} \quad \hat{f}(D) = \frac{1}{|\mathcal{D}|} \sum_{D_0 \in \mathcal{D}} Z_0 \quad \text{and} \quad a \neq 0.
$$
The variance parameter of Theorem 1 $\sigma_n^2 = \text{Var}(\tilde{h}_n(Z_0)) = 4a^2\text{Var}(Z_0)$ when $\tilde{h}_n(z) = \mathbb{E}[h_n(z, Z_{1:n}(1-1/k))]$, and the loss stability $\gamma_{\text{loss}}(h_n) = \frac{n\text{Var}(Z_0)^2}{\sigma_n^2 \text{(1-1/k)}} = o(\sigma_n^2/n)$. Consequently, Theorem 2 implies asymptotic linearity. The uniform integrability condition of Theorem 1 also holds. Together, these results imply that the CLT of Theorem 1 is applicable. However, whenever $Z_0$ does not have a fourth moment, the mean-square stability (3.1) is infinite.

**Proof** Introduce the shorthand $m = n(1-1/k)$, fix any $\mathcal{D}$ with $|\mathcal{D}| = m$, and suppose $\mathcal{D}z_0$ is formed by swapping $z_0'$ for an independent point $z_0''$ in $\mathcal{D}$. For any $z$ we have

$$(z - \hat{f}(\mathcal{D}))^2 - (z - \hat{f}(\mathcal{D}z_0))^2 = (\hat{f}(\mathcal{D}) - \hat{f}(\mathcal{D}z_0))(2z - \hat{f}(\mathcal{D}) - \hat{f}(\mathcal{D}z_0)) = \frac{1}{m}(Z_0'' - Z_0')(2z - \frac{1}{m}(Z_0'' + Z_0') - 2(\hat{f}(\mathcal{D}) - \frac{1}{m}Z_0')) = \frac{2}{m}(Z_0'' - Z_0')(z - (\hat{f}(\mathcal{D}) - \frac{1}{m}Z_0')) - \frac{1}{m^2}(Z_0''^2 - Z_0'^2).$$

Hence, the mean-square stability equals

$$\mathbb{E}[(Z_0 - \hat{f}(\mathcal{D}))^2 - (Z_0 - \hat{f}(\mathcal{D}z_0))^2] = \frac{1}{m}\mathbb{E}[(Z_0''^2 - Z_0'^2)^2] + \frac{4}{m^2}\mathbb{E}[(Z_0'' - Z_0')^2]\mathbb{E}[(Z_0 - (\hat{f}(\mathcal{D}) - \frac{1}{m}Z_0'))^2] = \frac{1}{m}\mathbb{E}[(Z_0'' - Z_0')^2] + \frac{4}{m^2}\mathbb{E}[(Z_0'' - Z_0')^2]\mathbb{E}[(Z_0 - (\hat{f}(\mathcal{D}) - \frac{1}{m}Z_0'))^2] \geq \frac{2}{m^2}\mathbb{E}[(Z_0'' - Z_0')^2]$$

since $\mathbb{E}[Z_0] = 0$, and $Z_0, Z_0', Z_0''$, $\hat{f}(\mathcal{D}) - \frac{1}{m}Z_0'$ are mutually independent.

Moreover, the loss stability equals

$$\mathbb{E}[(Z_0 - \hat{f}(\mathcal{D}))^2 - (Z_0 - \hat{f}(\mathcal{D}z_0))^2] = \frac{1}{m^2}\mathbb{E}[(Z_0'' - Z_0')^2]\mathbb{E}[(Z_0 - (\hat{f}(\mathcal{D}) - \frac{1}{m}Z_0'))^2] = \frac{1}{m}\mathbb{E}[(Z_0'' - Z_0')^2]\mathbb{E}[(Z_0 - (\hat{f}(\mathcal{D}) - \frac{1}{m}Z_0'))^2] = \frac{2}{m^2}\mathbb{E}((Z_0'' - Z_0')^2)^2.$$ 

Finally, for any $z$, $\mathbb{E}[(z - \hat{f}(\mathcal{D}))^2 - (z - a)^2] = \frac{1}{m}\mathbb{E}[\text{Var}(Z_0)] + 2za - a^2$. Consequently, for $\tilde{h}_n(Z_0) = \mathbb{E}[h_n(Z_0, \mathcal{D}) | Z_0]$, we get the following equalities:

$$\sigma_n^2 = \text{Var}(\tilde{h}_n(Z_0)) = 4a^2\text{Var}(Z_0), \quad \text{and} \quad \frac{(\tilde{h}_n(Z_0) - \mathbb{E}[\tilde{h}_n(Z_0)])^2}{\sigma_n^2} = Z_0^2/\text{Var}(Z_0).$$

The distribution of $Z_0^2/\text{Var}(Z_0)$ does not depend on $n$ and is integrable, so the sequence of $(\tilde{h}_n(Z_0) - \mathbb{E}[\tilde{h}_n(Z_0)])^2/\sigma_n^2$ is uniformly integrable. \hfill \square

**G** Loss of Surrogate Mean: constant $\sigma_n^2 \in (0, \infty)$, infinite $\bar{\sigma}_n^2$, vanishing conditional variance

The following example details a simple task in which (i) the CLT conditions of Theorem 1 and Theorem 3 hold and (ii) mean-square stability, $\sigma_n^2$, and loss stability are infinite.

**Example 2** (Loss of surrogate mean: constant $\sigma_n^2 \in (0, \infty)$, infinite $\bar{\sigma}_n^2$, vanishing conditional variance). Suppose $(Z_1)_{i \geq 1}$ are independent and identically distributed copies of a random element $Z_0 = (X_0, Y_0)$ with $Z_i = (X_i, Y_i)$ and $\mathbb{E}[X_0] = \mathbb{E}[Y_0]$. Consider $k$-fold cross-validation of the following prediction rule under squared error loss:

$$h_n((x, y), \mathcal{D}) = (y - \hat{f}(\mathcal{D}))^2 \quad \text{where} \quad \hat{f}(\mathcal{D}) \equiv \frac{1}{|\mathcal{D}|} \sum_{(x_0, y_0) \in \mathcal{D}} X_0.$$ 

The loss stability $\gamma_{\text{loss}}(h_n) = \frac{8\text{Var}(X_0)\text{Var}(Y_0)}{n^2(1-1/k)^2}$. The variance parameter of Theorem 1

$$\sigma_n^2 = \text{Var}(\tilde{h}_n(Z_0)) = \text{Var}((Y_0 - \mathbb{E}[Y_0])^2),$$

(G.1)
when \( \tilde{h}_n(z) = \mathbb{E}[h_n(z, Z_{1:n(1-1/k)})] \). Hence, if \( \mathbb{E}[X_0^2], \mathbb{E}[Y_0'] < \infty \), then \( \gamma_{\text{loss}}(h_n) = o(\sigma_n^2/n) \) and Theorem 2 implies asymptotic linearity. The uniform integrability condition of Theorem 1 also holds. Together, these results imply that the CLT of Theorem 1 is applicable.

If \( X_0 \) has no fourth moment, then the mean-square stability (3.1) is infinite.

If \( X_0 \) has no second moment, then the loss stability and the \([5, \text{Theorem 1}]\) variance parameter

\[
\hat{\sigma}^2_n = \mathbb{E}[\text{Var}(h_n(Z_0, Z_{1:n(1-1/k)}) \mid Z_{1:n(1-1/k)})] = \text{Var}((Y_0 - \mathbb{E}[Y_0])^2) + \frac{8\text{Var}(X_0)\text{Var}(Y_0)}{n(1-1/k)}
\]

are infinite. However,

\[
\sqrt{k}\mathbb{E}\left[\sqrt{\frac{1}{\sigma_n^2} \text{Var}_{Z_0}(h_n(Z_0, Z_{1:n(1-1/k)}) - \hat{h}_n(Z_0))}\right] = 2\sqrt{k}\sqrt{\frac{\text{Var}(Y_0)}{\text{Var}(X_0)}}\mathbb{E}[\hat{f}(Z_{1:n(1-1/k)}) - \mathbb{E}[X_0]].
\]

Hence, if \( \mathbb{E}[Y_0^4] < \infty \) and \( k = O(1) \), \( L^1 \) asymptotic linearity follows from Theorem 3, the uniform integrability condition of Theorem 1 still holds, and the CLT of Theorem 1 holds with the finite variance parameter \((G.1)\).

**Proof** Without loss of generality, we will assume \( \mathbb{E}[X_0] = \mathbb{E}[Y_0] = 0 \); the formulas in the general case are obtained by replacing \( X_0 \) with \( X_0 - \mathbb{E}[X_0] \) and similarly for \( Y_0 \). Introduce the shorthand \( m = n(1 - 1/k) \), fix any \( D \) with \( |D| = m \), and suppose \( D^{Z_0'} \) is formed by swapping \( Z_0' \) for an independent point \( Z_0'' \) in \( D \). For any \( z = (x, y) \) we have

\[
(y - \hat{f}(D))^2 - (y - \hat{f}(D^{Z_0''}))^2 = (\hat{f}(D) - \hat{f}(D^{Z_0''}))(2y - \hat{f}(D) - \hat{f}(D^{Z_0''}))
\]

\[
= \frac{1}{m}(X_0'' - X_0')(2y - \hat{f}(D) - \hat{f}(D^{Z_0''}))
\]

\[
= \frac{1}{m}(X_0'' - X_0')(2y - \frac{1}{m}(X_0'' + X_0') - 2(\hat{f}(D) - \frac{1}{m}X_0''))
\]

\[
= \frac{1}{m}(X_0'' - X_0')(y - (\hat{f}(D) - \frac{1}{m}X_0'')) - \frac{1}{mt}(X_0''^2 - X_0'^2).
\]

Hence, the mean-square equality holds

\[
\mathbb{E}[(Y_0 - \hat{f}(D))^2 - (Y_0 - \hat{f}(D^{Z_0''}))^2] = \frac{1}{m^2}\mathbb{E}[(X_0'' - X_0')^2] + \frac{1}{m^2}\mathbb{E}[(X_0'' - X_0')^2]\mathbb{E}[(Y_0 - (\hat{f}(D) - \frac{1}{m}X_0'')^2)]
\]

\[
- \frac{4}{m^2}\mathbb{E}[(X_0'' - X_0')(X_0''^2 - X_0'^2)]\mathbb{E}[(Y_0 - (\hat{f}(D) - \frac{1}{m}X_0''))^2]
\]

\[
= \frac{1}{m^2}\mathbb{E}[(X_0'' - X_0')^2] + \frac{1}{m^2}\mathbb{E}[(X_0'' - X_0')^2]\mathbb{E}[(Y_0 - (\hat{f}(D) - \frac{1}{m}X_0''))^2]
\]

\[
\geq \frac{2}{m^2}\text{Var}((X_0 - \mathbb{E}[X_0])^2)
\]

since \( \mathbb{E}[Y_0] = 0 \), and \( Z_0, Z_0', Z_0'', \hat{f}(D) - \frac{1}{m}X_0'' \) are mutually independent.

Moreover, the loss stability equals

\[
\mathbb{E}[(Y_0 - \hat{f}(D))^2 - (Y_0 - \hat{f}(D^{Z_0''}))^2] - \mathbb{E}_Y[(Y_0 - \hat{f}(D))^2] - (Y_0 - \hat{f}(D^{Z_0''}))^2]
\]

\[
= \frac{4}{m^2}\mathbb{E}[(X_0'' - X_0')^2]\mathbb{E}[(Y_0 - \mathbb{E}[Y_0])^2] = \frac{8}{m^2}\text{Var}(X_0)\text{Var}(Y_0).
\]

Next note that, for any \( y, y' \),

\[
\mathbb{E}[(y - \hat{f}(D))^2 - (y' - \hat{f}(D))^2] = (y - y')(y + y' - 2\mathbb{E}[^{\hat{f}(D)})]
\]

\[
= (y^2 - y'^2) - 2(y - y')\mathbb{E}[\hat{f}(D)] = y^2 - y'^2
\]

since \( \mathbb{E}[X_0] = 0 \). Therefore, \( \text{Var}(\mathbb{E}[h_n(Z_0, D) \mid Z_0]) = \frac{1}{2}\mathbb{E}[(Y_0^2 - Y_0'^2)^2] = \text{Var}(Y_0') \).

For any \( y \), \( \mathbb{E}[(y - \hat{f}(D))^2] = y^2 + \mathbb{E}[\hat{f}(D)^2] \), since \( \mathbb{E}[X_0] = 0 \). Consequently, for \( \tilde{h}_n(Z_0) = \mathbb{E}[h_n(Z_0, D) \mid Z_0] \), we get the following equalities:

\[
\sigma_n^2 = \text{Var}(\tilde{h}_n(Z_0)) = \text{Var}(Y_0'), \quad \text{and}
\]

\[
(\tilde{h}_n(Z_0) - \mathbb{E}[^{\tilde{h}_n(Z_0)}])^2/\sigma_n^2 = (Y_0^2 - \mathbb{E}[Y_0^2])^2/\text{Var}(Y_0').
\]
The distribution of \((Y_0^2 - \mathbb{E}[Y_0^2])^2 / \text{Var}(Y_0^2)\) does not depend on \(n\) and is integrable, so the sequence of \((\hat{h}_n(Z_0) - \mathbb{E}[\hat{h}_n(Z_0)])^2 / \sigma^2_{\hat{n}}\) is uniformly integrable.

Since 
\[
(y - \hat{f}(D))^2 - (y' - \hat{f}(D))^2 = (y^2 - y'^2) - 2(y - y')\hat{f}(D)
\]
we can compute the variance parameter of [5],
\[
\sigma^2_n = \mathbb{E}[\text{Var}(h_n(Z_0, D) | D)] = \mathbb{E}[|h_n(Z_0, D) - \mathbb{E}[h_n(Z_0, D)]|^2] = \frac{1}{2} \mathbb{E}[(h_n(Z_0, D) - h_n(Z_0', D))^2] = \frac{1}{2} \mathbb{E}[(Y_0^2 - Y_0'^2)^2] + 4 \mathbb{E}[(Y_0 - Y_0')^2] \mathbb{E}[\hat{f}(D)^2] - \mathbb{E}[(y^2 - y'^2) - 2(y - y')\hat{f}(D) - (y^2 - y'^2)]
\]
\[
= \text{Var}(Y_0^2) + 8 \text{Var}(Y_0) \frac{1}{m} \text{Var}(X_0),
\]

since \(\mathbb{E}[\hat{f}(D)] = 0\) and \(\hat{f}(D), Y_0, Y_0'\) are mutually independent.

Finally, let’s compute \(\sqrt{\mathbb{E}} \mathbb{E} \left[ \frac{1}{\sigma^2_n} \text{Var}_{Z_0}(h_n(Z_0, D) - \hat{h}_n(Z_0)) \right] \).

For any \(y, y'\),
\[
((y - \hat{f}(D))^2 - \mathbb{E}[(y - \hat{f}(D))^2]) - ((y' - \hat{f}(D))^2 - \mathbb{E}[(y' - \hat{f}(D))^2]) = (y^2 - y'^2) - 2(y - y')\hat{f}(D) - (y^2 - y'^2)
\]
so that \(\text{Var}(h_n(Z_0, D) - h_n(Z_0)) = \frac{1}{2} \mathbb{E}((-2(Y_0 - Y_0')\hat{f}(D))^2 | D) = 4 \text{Var}(Y_0)(\hat{f}(D))^2 \).

Then
\[
\sqrt{\mathbb{E}} \mathbb{E} \left[ \frac{1}{\sigma^2_n} \text{Var}_{Z_0}(h_n(Z_0, D) - \hat{h}_n(Z_0)) \right] = 2 \sqrt{\mathbb{E}} \sqrt{\frac{\text{Var}(Y_0)}{\frac{1}{m} \text{Var}(X_0)}} ||\hat{f}(D)||. \quad (G.2)
\]

If \(||X_0|| < \infty\), the family of empirical averages \(\left\{ \frac{1}{m} \sum_{i=1}^{m} X_i : m \geq 1 \right\}\) is uniformly integrable and the weak law of large numbers implies that \(\hat{f}(D)\) converges to 0 in probability. Hence, \(\hat{f}(D) \overset{L^1}{\rightarrow} 0\). The quantity \((G.2)\) then goes to zero when \(k = O(1)\). 

\(\Box\)

### H  Proof of Proposition 2: Variance comparison

Proposition 2 will follow from the following more general result.

**Proposition 5.** Fix any \(j \in [k]\), and define \(\sigma^2_{n,j} \triangleq \mathbb{E}(\text{Var}(h_n(Z_0, Z_{B_j}) | Z_0))\) and \(\tilde{\sigma}^2_{n,j} \triangleq \mathbb{E}(\text{Var}(h_n(Z_0, Z_{B_j}) | Z_{B_j}))\). Then
\[
\sigma^2_{n,j} \leq \tilde{\sigma}^2_{n,j} \leq \sigma^2_{n,j} + \frac{|B_j|}{2} \gamma_{\text{loss}}(h_n),
\]
where the first inequality is strict whenever \(h'_n(Z_0, Z_{B_j}) = h_n(Z_0, Z_{B_j}) - \mathbb{E}[h_n(Z_0, Z_{B_j}) | Z_{B_j}]\) depends on \(Z_{B_j}\).

**Proof** For all \(j \in [k]\), we can rewrite both variance parameters.
\[
\tilde{\sigma}^2_{n,j} = \mathbb{E}(\text{Var}(h_n(Z_0, Z_{B_j}) | Z_{B_j})) = \mathbb{E}(h'_n(Z_0, Z_{B_j}) - \mathbb{E}[h'_n(Z_0, Z_{B_j}) | Z_{B_j}] | Z_{B_j})^2 = \text{Var}(h'_n(Z_0, Z_{B_j})).
\]
\[
\sigma^2_{n,j} = \mathbb{E}(\text{Var}(h_n(Z_0, Z_{B_j}) | Z_0)) = (\mathbb{E}[h_n(Z_0, Z_{B_j}) | Z_0] - \mathbb{E}[h_n(Z_0, Z_{B_j})])^2 = (\mathbb{E}[h'_n(Z_0, Z_{B_j}) | Z_0])^2 = \text{Var}(h'_n(Z_0, Z_{B_j})).
\]
\[
\sigma^2_{n,j} - \mathbb{E}(\text{Var}(h'_n(Z_0, Z_{B_j}) | Z_0)) \leq \tilde{\sigma}^2_{n,j},
\]

22
where the final inequality is strict whenever \( \mathbb{E}[\text{Var}(h_n'(Z_0, Z_{B_j}) | Z_0)] \) is non-zero.

Since every non-constant variable has either infinite or strictly positive variance, 
\( \mathbb{E}[\text{Var}(h_n'(Z_0, Z_{B_j}) | Z_0)] = 0 \iff h_n'(Z_0, Z_{B_j}) = \mathbb{E}[h_n'(Z_0, Z_{B_j}) | Z_0] \), that is, if and only if \( h_n(Z_0, Z_{B_j}) = h_n(Z_0, Z_{B_j}) - \mathbb{E}[h_n(Z_0, Z_{B_j}) | Z_{B_j}] \) is independent of \( Z_{B_j} \).

Finally, we know from Lemma 1 that the difference \( \hat{\sigma}^2_{n,j} - \sigma^2_{n,j} = \mathbb{E}[\text{Var}(h_n'(Z_0, Z_{B_j}) | Z_0)] \leq \frac{1}{2} |B_j| \gamma_{\text{loss}}(h_n). \)

Proposition 2 then follows from Proposition 5 since the \( Z_i \)'s are i.i.d. and, when \( k \) divides \( n \), the only possible size for \( B_j \) is \( n(1 - 1/k) \).

I Proof of Theorem 4: Consistent within-fold estimate of asymptotic variance

We will prove the following more detailed statement from which Theorem 4 will follow.

**Theorem 9** (Consistent within-fold estimate of asymptotic variance). Suppose that \( k \leq n/2 \) and that \( k \) divides \( n \) evenly. Under the notation of Theorem 1 with \( m = n(1 - 1/k) \), 
\( \bar{h}_n(z) = \mathbb{E}[h_n(z, Z_{1:m})], h_n'(Z_0, Z_{1:m}) = h_n(Z_0, Z_{1:m}) - \mathbb{E}[h_n(Z_0, Z_{1:m}) | Z_{1:m}] \) and \( \bar{h}_n'(z) = \mathbb{E}[h_n'(z, Z_{1:m})] \), define the within-fold variance estimate

\[
\hat{\sigma}^2_{n,in} = \frac{1}{k} \sum_{j=1}^{k} \frac{1}{(n/k)-1} \sum_{i \in B_j}^{} \left( h_n(Z_i, Z_{B_j}) - \frac{k}{n} \sum_{i' \in B_j}^{} h_n(Z_{i'}, Z_{B_j}) \right)^2.
\]

If \((Z_i)_{i \geq 1}\) are i.i.d. copies of a random element \( Z_0 \), then

\[
\mathbb{E}[\hat{\sigma}^2_{n,in} - \sigma^2_n] \leq \frac{2n^2}{n-k} \gamma_{\text{loss}}(h_n) + 2 \sqrt{\frac{2n^2}{n-k} \gamma_{\text{loss}}(h_n)} \sigma^2_n + \sqrt{\frac{1}{n} \mathbb{E}[\bar{h}_n'(Z_0)^4]} + \frac{3k-n}{n(n-k)} \sigma^4_n
\]

and there exists an absolute constant \( C \) specified in the proof such that

\[
\mathbb{E}[\hat{\sigma}^2_{n,in} - \sigma^2_n] \leq 4C n^4 \gamma_4(h_n') + 8 \sqrt{\frac{C n^4}{(n-k)} \gamma_4(h_n')} \left( \frac{1}{n} \mathbb{E}[\bar{h}_n'(Z_0)^4] + \frac{3k-n}{n(n-k)} \sigma^4_n + \sigma^4_n \right)
\]

(1.1)

where \( \gamma_4(h_n') \equiv \frac{1}{m} \sum_{i=1}^{m} \mathbb{E}[\left( h_n'(Z_0, Z_{1:m}) - h_n'(Z_0, \tilde{Z}_{1:m}) \right)^4] \). Here, \( \tilde{Z}_{1:m} \) denotes \( Z_{1:m} \) with \( Z_i \) replaced by an i.i.d. copy independent of \( Z_{0:m} \).

Moreover,

\[
\mathbb{E}[|\hat{\sigma}^2_{n,in} - \sigma^2_n|] \leq \frac{2n^2}{n-k} \gamma_{\text{loss}}(h_n) + 2 \sqrt{\frac{2n^2}{n-k} \gamma_{\text{loss}}(h_n)} \sigma^2_n + \sqrt{\frac{2}{n(n-k)^2} \sigma^4_n} + o(\sigma^2_n)
\]

(1.2)

wherever the sequence of \( (\bar{h}_n(Z_0) - \mathbb{E}[\bar{h}_n(Z_0)])^2 / \sigma^2_n \) is uniformly integrable.

**Proof**

**Eliminating training set randomness** We begin by approximating our variance estimate

\[
\hat{\sigma}^2_{n,in} = \frac{1}{k} \sum_{j=1}^{k} \frac{1}{(n/k)-1} \sum_{i \in B_j}^{} \left( h_n(Z_i, Z_{B_j}) - \frac{k}{n} \sum_{i' \in B_j}^{} h_n(Z_{i'}, Z_{B_j}) \right)^2
\]

by a quantity eliminating training set randomness in each summand,

\[
\hat{\sigma}^2_{n,in,\text{approx}}(z) \equiv \frac{1}{k} \sum_{j=1}^{k} \frac{1}{(n/k)-1} \sum_{i \in B_j}^{} \left( h_n'(Z_i) - \frac{k}{n} \sum_{i' \in B_j}^{} h_n'(Z_{i'}) \right)^2,
\]

where \( h_n'(z) = \mathbb{E}[h_n'(z, Z_{1:m})] \). Note that \( \hat{h}_n'(Z_0) \) has expectation 0.

By Cauchy–Schwarz, we have

\[
|\hat{\sigma}^2_{n,in} - \hat{\sigma}^2_{n,in,\text{approx}}| \leq \Delta + 2 \sqrt{\Delta \hat{\sigma}^2_{n,in,\text{approx}}}
\]
for the error term
\[
\Delta \triangleq \frac{1}{k} \sum_{j=1}^{k} \sum_{i \in B_j} \left( h_n'(Z_i, Z_{B_j}) - \tilde{h}_n(Z_i) \right) + \frac{\kappa}{n} \sum_{i \in B_j} \left( \tilde{h}_n'(Z_i) - \frac{\kappa}{n} \sum_{i' \in B_j} h_n'(Z_{i'}, Z_{B_j}) \right)^2
\]
\[
\leq 2 \frac{1}{k} \sum_{j=1}^{k} \sum_{i \in B_j} \left( h_n'(Z_i, Z_{B_j}) - \tilde{h}_n(Z_i) \right)^2
\]
\[
+ 2 \frac{1}{k} \sum_{j=1}^{k} \sum_{i \in B_j} \left( \frac{\kappa}{n} \sum_{i' \in B_j} \left( \tilde{h}_n'(Z_{i'}) - h_n'(Z_{i'}, Z_{B_j}) \right) \right)^2
\]
\[
\leq 2 \frac{1}{k} \sum_{j=1}^{k} \sum_{i \in B_j} \left( h_n'(Z_i, Z_{B_j}) - \tilde{h}_n(Z_i) \right)^2
\]
\[
+ 2 \frac{1}{k} \sum_{j=1}^{k} \sum_{i \in B_j} \left( \frac{\kappa}{n} \sum_{i' \in B_j} \left( \tilde{h}_n'(Z_{i'}) - h_n'(Z_{i'}, Z_{B_j}) \right) \right)^2
\]
\[
= \frac{4}{n-k} \sum_{j=1}^{k} \sum_{i \in B_j} \left( h_n'(Z_i, Z_{B_j}) - \tilde{h}_n(Z_i) \right)^2
\]

where we have used Jensen’s inequality twice.

Thus,
\[
\Delta^2 \leq \frac{16n^2}{(n-k)^2} \frac{1}{n} \sum_{j=1}^{k} \sum_{i \in B_j} \left( h_n'(Z_i, Z_{B_j}) - \tilde{h}_n(Z_i) \right)^4
\]
\[
= \frac{16n}{(n-k)^2} \sum_{j=1}^{k} \sum_{i \in B_j} \left( h_n'(Z_i, Z_{B_j}) - \tilde{h}_n(Z_i) \right)^4
\]

by Jensen’s inequality.

**Controlling the error \( \Delta \)** We will first control the error term \( \Delta \). By the bound (1.3) and the conditional Efron–Stein inequality (Lemma 1), we have
\[
\mathbb{E}[\Delta] \leq \frac{4}{n-k} \sum_{j=1}^{k} \sum_{i \in B_j} \mathbb{E}[\left( h_n'(Z_i, Z_{B_j}) - \tilde{h}_n(Z_i) \right)^2]
\]
\[
= \frac{4}{n-k} \sum_{j=1}^{k} \sum_{i \in B_j} \left[ \mathbb{E}[\left( h_n'(Z_i, Z_{B_j}) - \mathbb{E}[h_n'(Z_i, Z_{B_j})] \right)^2] \right]
\]
\[
= \frac{4}{n-k} \sum_{j=1}^{k} \sum_{i \in B_j} \left[ \mathbb{E}[\left( h_n'(Z_i, Z_{B_j}) - \mathbb{E}[h_n'(Z_i, Z_{B_j})] \right)^2 \right] | Z_i]
\]
\[
= \frac{4}{n-k} \sum_{j=1}^{k} \sum_{i \in B_j} \left[ \mathbb{E}[\left( h_n'(Z_i, Z_{B_j}) - \mathbb{E}[h_n'(Z_i, Z_{B_j})] \right)^2 \right] | Z_i]
\]
\[
\leq \frac{2}{n-k} \sum_{j=1}^{k} \sum_{i \in B_j} \mathbb{V}[h_n'(Z_i, Z_{B_j})]
\]
\[
\leq \frac{2n^2}{n-k} \gamma_{ms}(h_n')
\]

(1.5)

**Controlling \( \Delta^2 \)** In the following, for any \( j \in [k] \) and \( i' \in B_j \), \( Z_{B_j}^{i'} \) is \( B_j \) with \( Z_{i'} \) replaced by \( Z_0 \). By the bound (1.4) and Boucheron et al. [12, Thm. 2], and by noting that \( x^4 = x_+^4 + x_-^4 \) where \( x_+ = \max(x, 0) \) and \( x_- = \max(-x, 0) \), we have
\[
\mathbb{E}[\Delta^2] \leq \frac{16n}{(n-k)^2} \sum_{j=1}^{k} \sum_{i \in B_j} \mathbb{E}[\left( h_n'(Z_i, Z_{B_j}) - \tilde{h}_n(Z_i) \right)^4]
\]
\[
= \frac{16n}{(n-k)^2} \sum_{j=1}^{k} \sum_{i \in B_j} \left[ \mathbb{E}[\left( h_n'(Z_i, Z_{B_j}) - \mathbb{E}[h_n'(Z_i, Z_{B_j})] \right)^4] \right]
\]
\[
= \frac{16n}{(n-k)^2} \sum_{j=1}^{k} \sum_{i \in B_j} \left[ \mathbb{E}[\left( h_n'(Z_i, Z_{B_j}) - \mathbb{E}[h_n'(Z_i, Z_{B_j})] \right)^4] \right] | Z_i]
\]
\[
+ \mathbb{E}[\left( h_n'(Z_i, Z_{B_j}) - \mathbb{E}[h_n'(Z_i, Z_{B_j})] \right)^4] | Z_i]
\]
\[
\leq \frac{16n}{(n-k)^2} (1 - \frac{1}{2})^2 (\frac{2}{3})^2 16 \sum_{j=1}^{k} \sum_{i \in B_j} \left[ \mathbb{E}[\left( \sum_{i' \in B_j} (h_n'(Z_i, Z_{B_j}) - h_n'(Z_i, Z_{B_j}^{i'}))^2 \right)^2] \right]
\]
\[
+ \mathbb{E}[\left( \sum_{i' \in B_j} (h_n'(Z_i, Z_{B_j}) - h_n'(Z_i, Z_{B_j}^{i'}))^2 \right)^2] \right]
\]
\[
\leq \frac{16n}{(n-k)^2} \frac{3864n}{49} \sum_{j=1}^{k} \sum_{i \in B_j} \left[ \mathbb{E}[\left( \sum_{i' \in B_j} (h_n'(Z_i, Z_{B_j}) - h_n'(Z_i, Z_{B_j}^{i'}))^2 \right)^2] \right]
\]
\[
\leq \frac{36864n}{49(n-k)^2} \sum_{j=1}^{k} \sum_{i \in B_j} \left[ \mathbb{E}[\left( \sum_{i' \in B_j} (h_n'(Z_i, Z_{B_j}) - h_n'(Z_i, Z_{B_j}^{i'}))^2 \right)^4] \right]
\]
\[
+ \sum_{i' \in B_j} \mathbb{E}[\left( \sum_{i' \in B_j} (h_n'(Z_i, Z_{B_j}) - h_n'(Z_i, Z_{B_j}^{i'}))^4 \right)]
\]

24
Moreover, by the independence of our datapoints, we have

\[
E[(h_n'(Z_i, Z_{B_i}) - h_n'(Z_{i1}, Z_{B_{i1}}))^4]
\]

where \( \gamma_4(h_n') = \frac{1}{m} \sum_{i=1}^{m} E[(h_n'(Z_0, Z_{1:m}) - h_n'(Z_0, Z_{1:m}'))^4] \) and \( C = 36864/49 \).

**Controlling the error** \( \hat{\sigma}_{n,in,approx}^2 - \sigma_n^2 \) To control the error \( \hat{\sigma}_{n,in,approx}^2 - \sigma_n^2 \), we first rewrite \( \hat{\sigma}_{n,in,approx}^2 \) as

\[
\hat{\sigma}_{n,in,approx}^2 = \frac{1}{n} \sum_{i=1}^{n} \sum_{i' \in B_i} \left( \hat{h}_n'(Z_i) - \frac{1}{n} \sum_{i' \in B_j} \hat{h}_n'(Z_i') \right)^2
\]

We rewrite it once again to find

\[
\hat{\sigma}_{n,in,approx}^2 = \frac{1}{n} \sum_{j=1}^{k} \sum_{i \in B_j} \hat{h}_n'(Z_i)^2 - \frac{1}{k} \sum_{j=1}^{k} W_j
\]

where

\[
W_j = \frac{1}{(\binom{n}{k})^2} \sum_{i', i'' \in B_j} \hat{h}_n'(Z_i) \hat{h}_n'(Z_i') \hat{h}_n'(Z_{i''}) \hat{h}_n'(Z_{i''}).
\]

Since \( (W_j)_{j \in [k]} \) are i.i.d. with mean 0 and for \( i_1 < i_1' \) and \( i_2 < i_2' \)

\[
E[\hat{h}_n'(Z_{i_1}) \hat{h}_n'(Z_{i_1'}) \hat{h}_n'(Z_{i_2}) \hat{h}_n'(Z_{i_2'})] = 0
\]

whenever \( i_1 \neq i_2 \) or \( i_1' \neq i_2' \), we have

\[
E[(\frac{1}{k} \sum_{j=1}^{k} W_j)^2] = \frac{1}{k} \text{Var}(W_1) = \frac{1}{k} \left( \frac{1}{(\binom{n}{k})^2} \sum_{i,i' \in B_j} E[\hat{h}_n'(Z_i)^2 \hat{h}_n'(Z_{i'})^2] \right)
\]

\[
= \frac{1}{k} \left( \frac{1}{(\binom{n}{k})^2} \sum_{i < i'} E[\hat{h}_n'(Z_i)^2] E[\hat{h}_n'(Z_{i'})^2] \right)
\]

\[
= \frac{1}{k} \left( \frac{1}{(\binom{n}{k})^2} \sum_{i < i'} \sigma_n^4 = \frac{1}{k} \left( \frac{1}{\binom{n}{k}} \right)^2 \sigma_n^4 = \frac{2}{n(n(k-1))} \sigma_n^4 \right)
\]

(1.8)

by noticing that \( E[\hat{h}_n'(Z_0)^2] = \text{Var}(\hat{h}_n'(Z_0)) = \text{Var}(\hat{h}_n(Z_0)) = \sigma_n^2 \).

Moreover, by the independence of our datapoints, we have

\[
E[\hat{h}_n'(Z_{i_1})^2 \hat{h}_n'(Z_{i_2}) \hat{h}_n'(Z_{i_1'}) \hat{h}_n'(Z_{i_2'})] = 0
\]

for all \( i_1, i_2, i_1', i_2' \in [n] \) such that \( i_2 < i_2' \), and thus

\[
E[(\hat{\sigma}_{n,in,approx}^2 - \sigma_n^2)^2] = \text{Var}(\hat{\sigma}_{n,in,approx}^2)
\]

\[
= \frac{1}{n} \text{Var}(\hat{h}_n'(Z_0)^2) + \frac{2}{n(n(k-1))} \sigma_n^4
\]

\[
= \frac{1}{n} E[\hat{h}_n'(Z_0)^4] + \frac{3k-n}{n(n-k)} \sigma_n^4.
\]

(1.9)

**Putting the pieces together** We have

\[
E[\sqrt{\Delta \hat{\sigma}_{n,in,approx}}] \leq \sqrt{E[\Delta]}E[\hat{\sigma}_{n,in,approx}^2] \leq \sqrt{\frac{2n^2}{n-k}} \gamma_{loss}(h_n) \sigma_n^2
\]

by Cauchy–Schwarz and the bound (1.5).
We also have
\[
E[\Delta \hat{\sigma}^2_{n,in,approx}] \leq \sqrt{E[\Delta^2]E[\hat{\sigma}^4_{n,in,approx}]}
= \sqrt{E[\Delta^2](\text{Var}(\hat{\sigma}^2_{n,in,approx}) + E[\hat{\sigma}^2_{n,in,approx}]^2) - \frac{2k-n}{n(n-k)}\sigma_n^4 + \sigma_n^2}
\]
by Cauchy-Schwarz, (1.6) and (1.9).

Assembling our results with the triangle inequality and Cauchy–Schwarz for the \(L^1\) bound and with Jensen’s inequality for the \(L^2\) bound, we find that
\[
E[|\hat{\sigma}^2_{n,in} - \sigma_n^2|] \leq E[|\hat{\sigma}^2_{n,in} - \hat{\sigma}^2_{n,in,approx}|] + E[|\hat{\sigma}^2_{n,in,approx} - \sigma_n^2|]
\leq E[\Delta] + 2E[\sqrt{\Delta \hat{\sigma}^2_{n,in,approx}}] + \sqrt{E[\hat{\sigma}^2_{n,in,approx} - \sigma_n^2]^2}
\leq 2n^2 \gamma_{\text{loss}}(h_n) + 2\sqrt{\frac{2n^2}{n-k} \gamma_{\text{loss}}(h_n)\sigma_n^2} + \sqrt{\frac{1}{n}E[h_n'(Z_0)^4] + \frac{2k-n}{n(n-k)}\sigma_n^4}
\]
and
\[
E[(\hat{\sigma}^2_{n,in} - \sigma_n^2)^2] \leq 2E[(\hat{\sigma}^2_{n,in} - \hat{\sigma}^2_{n,in,approx})^2] + 2E[(\hat{\sigma}^2_{n,in,approx} - \sigma_n^2)^2]
\leq 4E[\Delta^2] + 8E[\Delta \hat{\sigma}^2_{n,in,approx}] + 2E[(\hat{\sigma}^2_{n,in,approx} - \sigma_n^2)^2]
\leq 4\frac{Cn^4}{(n-k)^2} \gamma_4(h_n') + 8\sqrt{n} \frac{Cn^4}{(n-k)^2} \gamma_4(h_n') \left(\frac{1}{n}E[h_n'(Z_0)^4] + \frac{2k-n}{n(n-k)}\sigma_n^4 + \sigma_n^2\right) + 2\frac{1}{n}E[h_n'(Z_0)^4] + \frac{2k-n}{n(n-k)}\sigma_n^4
\]
as advertised.

In order to get the bound
\[
E[|\hat{\sigma}^2_{n,in} - \sigma_n^2|] \leq \frac{2n^2}{n-k} \gamma_{\text{loss}}(h_n) + 2\sqrt{\frac{2n^2}{n-k} \gamma_{\text{loss}}(h_n)\sigma_n^2} + \frac{2}{n(n-k-1)}\sigma_n^4 + o(\sigma_n^2)
\]
whenever the sequence of \((\hat{h}_n(Z_0) - E[\hat{h}_n(Z_0)])^2/\sigma_n^2\) is uniformly integrable, i.e., the sequence of \(\hat{h}_n'(Z_0)^2/\sigma_n^2\) is uniformly integrable, we need to argue that \(\frac{1}{n} \sum_{i=1}^n \hat{h}_n'(Z_i)^2/\sigma_n^2 \overset{L^1}{\to} 1\). Indeed, thanks to (1.7) and (1.8), this will lead to \(E[|\hat{\sigma}^2_{n,in,approx} - \sigma_n^2|] \leq \sqrt{\frac{2}{n(n-k-1)}\sigma_n^4} + o(\sigma_n^2)\).

To this end, we show that for any triangular i.i.d. array \((X_{n,i})_{n,i}\) such that \((X_{n,i})_{n,i \geq 1}\) is uniformly integrable, then the two conditions in the weak law of large numbers for triangular arrays of [23, Thm. 2.2.11] (stated below) are satisfied. We will also show that for such \((X_{n,i})_{n,i}\), \((S_n = \frac{1}{n} \sum_{i=1}^n X_{n,i})_{n \geq 1}\) is uniformly integrable. Together, these results will imply \(L^1\) convergence. We will then choose \(X_{n,i} = \hat{h}_n'(Z_i)^2/\sigma_n^2\) to get the desired result in our specific case.

**Theorem 10** (Weak law for triangular arrays [23, Thm. 2.2.11]). For each \(n\), let \(X_{n,i}, 1 \leq i \leq n\), be independent. Let \(b_n > 0\) with \(b_n \to \infty\), and let \(X_{n,i} = X_{n,i} I[|X_{n,i}| \leq b_n]\). Suppose that as \(n \to \infty\)

1. \[\sum_{i=1}^n P(|X_{n,i}| > b_n) \to 0,\] \,(I.10) with \(P\) \nand

2. \[b_n^{-2} \sum_{i=1}^n E[X_{n,i}^2] \to 0.\] \,(I.11)

If we let \(S_n = \sum_{i=1}^n X_{n,i}\) and \(a_n = \sum_{i=1}^n E[X_{n,i}]\), then \((S_n - a_n)/b_n \overset{P}{\to} 0\).

To prove our result, we specify the case of interest \(b_n = n\). First, \(nP(|X_{1,i}| > n) \leq E[|X_{1,i}| 1[|X_{1,i}| > n]] \leq \sup_{m \geq 1} E[|X_{m,i}| 1[|X_{m,i}| > n]] \to 0\) as \(n \to \infty\), because \((X_{1,i})_{n \geq 1}\) is uniformly integrable. Thus the first condition (I.10) holds.
Therefore, by (I.2), we have 
\[ \gamma \leq 4 \] 
which satisfies \( \mathbb{E}[X_{n,1}] = 1 \).

To verify the second condition (I.11), we will show that \( n^{-1} \mathbb{E}[X_n^2 1[X_n,1] \leq n]] \to 0 \). To this end, we need the following lemma, which gives a useful formulation of uniform integrability.

**Lemma 3** (De la Vallée Poussin Theorem [40, Thm. 22]). If \( (X_n)_{n \geq 1} \) is uniformly integrable, then there exists a nonnegative increasing function \( G \) such that \( G(t)/t \to \infty \) as \( t \to \infty \) and \( \sup_n \mathbb{E}[G(X_n)] < \infty \).

With such a function \( G \), fix any \( T \) such that \( G(t)/t \geq 1 \) for all \( t \geq T \), so that \( t/G(t) \leq 1 \) for all \( t \geq T \). Using [23, Lem. 2.2.13] for the first equality, we can write
\[
\frac{1}{n} \mathbb{E}[X_n^2 1[X_n,1] \leq n]] = \frac{2}{n} \int_0^\infty y \mathbb{P}(X_n^2 1[X_n,1] \leq n]] > y dy
\]
\[
\leq \frac{2}{n} \int_0^T y \mathbb{P}(X_n^2 1[X_n,1] > y) dy
\]
\[
= \frac{2}{n} \int_0^T y \mathbb{P}(X_n^2 1[X_n,1] > y) dy
\]
\[
\leq \frac{T^2}{n} + \frac{2}{n} \int_0^T y \mathbb{P}(X_n^2 1[X_n,1] > y) dy
\]
\[
\leq \frac{T^2}{n} + \mathbb{E}[G(X_n)] \frac{2}{n} \int_0^T y/G(y) dy
\]
\[
= \frac{T^2}{n} + o(1),
\]
where the penultimate line follows from Markov’s inequality and the last line comes from the following lemma since \( \sup_{y \geq T} y/G(y) \leq 1 \) and \( y/G(y) \to 0 \).

**Lemma 4.** If \( f(y) \to 0 \) as \( y \to \infty \) and \( \sup_{y \geq T} |f(y)| \leq M \), then \( \frac{1}{n} \int_0^n f(y) dy \to 0 \).

**Proof** Let \( f_n(z) = f(nz) 1[z > T/n] \), and note that, for any \( z \geq 0 \), \( f_n(z) \to 0 \) as \( n \to \infty \). Then
\[
\frac{1}{n} \int_0^n f(y) dy = \int_0^1 \int_0^T f(nz) dz
\]
\[
= \int_0^1 f_n(z) dz
\]
\[
\to 0
\]
by the bounded convergence theorem.

Consequently, the second condition (I.11) holds.

Moreover, \( (S_n = \frac{1}{n} \sum_{i=1}^n X_n)_{n \geq 1} \) is uniformly integrable whenever \( (X_n,i)_{n,i} \) is a triangular i.i.d. array such that \( (X_n,1)_{n \geq 1} \) is uniformly integrable for the following reasons:

1. \( \sup_n \mathbb{E}[[S_n]] \leq \sup_n \mathbb{E}[[X_n,1]] < \infty \) by triangle inequality and because \( (X_n,1)_{n \geq 1} \) is uniformly integrable.
2. For any \( \varepsilon > 0 \), let \( \delta > 0 \) such that for any event \( A \) satisfying \( \mathbb{P}(A) \leq \delta \), \( \sup_n \mathbb{E}[[X_n,1] 1[A]] \leq \varepsilon \). Such \( \delta \) exists because \( (X_n,1)_{n \geq 1} \) is uniformly integrable. Then \( \sup_n \mathbb{E}[[S_n]] \leq \varepsilon \) by triangle inequality.

The combination of convergence in probability and uniform integrability implies convergence in \( L^1 \).

As a result, \( \frac{1}{n} \sum_{i=1}^n \hat{h}_n(Z_i)^2 / \sigma_n^2 \to 1 \) as long as the sequence of \( \langle \hat{h}_n(Z) - \mathbb{E}[\hat{h}_n(Z)] \rangle^2 / \sigma_n^2 = \hat{h}_n(Z)^2 / \sigma_n^2 \) is uniformly integrable.

Therefore, \( \mathbb{E}[[\hat{\sigma}_n^2, \text{in}, \text{approx}, \sigma_n^2 - 1]] \leq \sqrt{\frac{2}{n(n-k-1)}} + o(1) \), and we get the result advertised.

If \( k \leq n/2 \), which is the case here since \( k < n \) and \( k \) divides \( n \), then \( \frac{2}{n(n-k-1)} \to 0 \) and \( \frac{2k-n}{n(n-k)} \to 0 \).

Therefore, by (I.2), we have \( \hat{\sigma}_n^2 - \hat{\sigma}_n^2 / \sigma_n^2 \to 0 \), i.e. \( \hat{\sigma}_n^2 / \sigma_n^2 \to 1 \), whenever the sequence of \( \langle \hat{h}_n(Z) - \mathbb{E}[\hat{h}_n(Z)] \rangle^2 / \sigma_n^2 \) is uniformly integrable and \( \gamma_{\text{loss}}(h_n) = o(\sigma_n^2) \), or equivalently \( \gamma_{\text{loss}}(h_n) = o(\sigma_n^2) \) since \( k \leq n/2 \), and, by (I.1), we have \( \hat{\sigma}_n^2 - \hat{\sigma}_n^2 / \sigma_n^2 \to 0 \), i.e. \( \hat{\sigma}_n^2 / \sigma_n^2 \to 1 \), whenever \( \mathbb{E}[\hat{h}_n(Z)^4] = \mathbb{E}[(\hat{h}_n(Z) - \mathbb{E}[\hat{h}_n(Z)])^4] = o(\sigma_n^4) \) and \( \gamma_4(h_n) = o(\sigma_n^2/k) \), or equivalently \( \gamma_4(h_n) = o(\sigma_n^2/k) \) since \( k \leq n/2 \).

Theorem 4 thus follows from Theorem 9.
Strengthening of the consistency result of [5, Prop. 1] We provide more details about the comparison of our $L^2$-consistency result with [5, Prop. 1]. We have $\gamma_4(h_n^4) \leq 16\gamma_4(h_n)$ and $\mathbb{E}[(h_n(Z_0) - h_n(Z))]^4 \leq 16\mathbb{E}[h_n(Z_0, Z_{1:m})]^4$ by Jensen’s inequality. Moreover, if $\sigma_n^2$ converges to a non-zero constant, since $\gamma_\text{loss}(h_n) \leq \gamma_m(h_n) \leq \sqrt{\gamma_4(h_n)}$, then $\gamma_\text{loss}(h_n) = o(\sigma_n^2/n)$ whenever $\gamma_4(h_n) = o(\sigma_n^2/n^2)$ and thus $\sigma_n^2$ converges to the same non-zero constant as $\sigma_n^2$ does by Proposition 2.

J  Proof of Theorem 5: Consistent all-pairs estimate of asymptotic variance

We will prove the following more detailed statement from which Theorem 5 will follow.

Theorem 11 (Consistent all-pairs estimate of asymptotic variance), Suppose that $k$ divides $n$ evenly. Under the notation of Theorem 1 with $m = n(1 - 1/k)$, $h_n(z) = \mathbb{E}[h_n(z, Z_{1:m})]$, $h_n'(Z_0, Z_{1:m}) = h_n(Z_0, Z_{1:m}) - \mathbb{E}[h_n(Z_0, Z_{1:m}) | Z_{1:m}]$ and $h_n'(z) = \mathbb{E}[h_n'(z, Z_{1:m})]$, define the all-pairs variance estimate

$$\hat{\sigma}_{n,\text{out}}^2 \triangleq \frac{1}{k} \sum_{j=1}^k \left( h_n(Z_i, Z_{B_j}) - \bar{R}_n \right)^2.$$

If $(Z_i)_{i \geq 1}$ are i.i.d. copies of a random element $Z_0$ and $\hat{\sigma}_{n}^2 = \mathbb{E}[h_n'(Z_0, Z_{1:m})^2]$, then

$$\mathbb{E}[|\hat{\sigma}_{n,\text{out}}^2 - \sigma_{n}^2|] \leq \left( 1 + \frac{n}{k} \right) \gamma_m(h_n) + 2\sqrt{2(1 + \frac{n}{k})} \gamma_m(h_n) \hat{\sigma}_{n}^2 + m \gamma_\text{loss}(h_n)$$

$$+ 2\sqrt{m \gamma_\text{loss}(h_n)(1 - \frac{1}{n})\sigma_n^2} + \frac{1}{n}(\mathbb{E}[h_n'(Z_0)^4] - \sigma_n^4) + \frac{1}{n}\sigma_n^4.$$

Moreover,

$$\mathbb{E}[|\hat{\sigma}_{n,\text{out}}^2 - \sigma_{n}^2|] \leq \left( 1 + \frac{n}{k} \right) \gamma_m(h_n) + 2\sqrt{2(1 + \frac{n}{k})} \gamma_m(h_n) \hat{\sigma}_{n}^2 + m \gamma_\text{loss}(h_n)$$

$$+ 2\sqrt{m \gamma_\text{loss}(h_n)(1 - \frac{1}{n})\sigma_n^2} + \frac{1}{n}\sigma_n^2 + o(\sigma_n^2). \quad (J.1)$$

whenever the sequence of $(\bar{h}_n(Z_0) - \mathbb{E}[\bar{h}_n(Z_0)])^2/\sigma_n^2$ is uniformly integrable.

Proof

A common training set for each validation point pair We begin by approximating our variance estimate

$$\hat{\sigma}_{n,\text{out}}^2 = \frac{1}{n^2} \sum_{j=1}^k \sum_{i \in B_j} \left( h_n(Z_i, Z_{B_j}) - \bar{R}_n \right)^2$$

by a quantity that employs the same training set for each pair of validation points $Z_{(i,i')}$,

$$\hat{\sigma}_{n,\text{out,approx1}}^2 \triangleq \frac{1}{n^2} \sum_{j=1}^k \sum_{i \in B_j, i' \in B_j} \frac{1}{2} \left( h_n(Z_i, Z_{B_j}) - h_n(Z_{i'}, Z_{B_j}) \right)^2$$

by a quantity that employs the same training set for each pair of validation points $Z_{(i,i')}$,

$$\hat{\sigma}_{n,\text{out,approx1}}^2 \triangleq \frac{1}{n^2} \sum_{j=1}^k \sum_{i \in B_j, i' \in B_j} \frac{1}{2} \left( h_n(Z_i, Z_{B_j}) - h_n(Z_{i'}, Z_{B_j}) \right)^2.$$

Here, for any $j \in [k]$ and $i' \in [n]$, $Z_{B_j}^{i'}$ is $Z_{B_j}$ with $Z_{i'}$ replaced by $Z_0$. By Cauchy–Schwarz, we have

$$|\hat{\sigma}_{n,\text{out}}^2 - \hat{\sigma}_{n,\text{out,approx1}}^2| \leq \Delta_1 + 2\sqrt{\Delta_1 \hat{\sigma}_{n,\text{out,approx1}}^2}$$

for the error term

$$\Delta_1 \triangleq \frac{1}{n^2} \sum_{j=1}^k \sum_{i \in B_j, i' \in B_j} \frac{1}{2} \left( h_n(Z_i, Z_{B_j}) - h_n(Z_{i'}, Z_{B_j}) + h_n(Z_{i'}, Z_{B_j}) - h_n(Z_i, Z_{B_j}) \right)^2$$

$$\leq \frac{1}{n^2} \sum_{j=1}^k \sum_{i \in B_j, i' \in B_j} \left( h_n(Z_i, Z_{B_j}) - h_n(Z_i, Z_{B_j}) \right)^2$$

$$+ \frac{1}{n^2} \sum_{j=1}^k \sum_{i \in B_j, i' \in B_j} \left( h_n(Z_{i'}, Z_{B_j}) - h_n(Z_{i'}, Z_{B_j}) \right)^2, \quad (J.2)$$

where we have used Jensen’s inequality in the final display.
Controlling the error $\Delta_1$ We will first control the error term $\Delta_1$. Note that, for $B_{j' \setminus (B_{j'} \cap B_j)} = \emptyset$. Hence, by the bound (J.2) and the conditional Efron-Stein inequality (Lemma 1), we have

$$
\mathbb{E}[\Delta_1] \leq \gamma_{ms}(h_n) + \frac{1}{n} \sum_{j,j' = 1}^{k} \sum_{i \in B_{j'}, i' \in B_{j'}} \mathbb{E}[(h_n(Z_{i'}, Z_{B_{j'}}) - h_n(Z_{i'}, Z_{B_{j'}}))^2] \\
\leq \gamma_{ms}(h_n) + \frac{n}{k} \gamma_{ms}(h_n) = (1 + \frac{n}{k}) \gamma_{ms}(h_n).
$$

(J.3)

Eliminating training set randomness We then approximate $\hat{\sigma}_{n,\text{out,approx},1}^2$ by a quantity eliminating training set randomness in each summand,

$$
\hat{\sigma}_{n,\text{out,approx},2}^2 \approx \frac{1}{n} \sum_{j,j' = 1}^{k} \sum_{i \in B_{j'}, i' \in B_{j'}} \frac{1}{2}(\tilde{h}'_n(Z_i) - \tilde{h}'_n(Z_{i'}))^2
$$

where $\tilde{h}'_n(z) = \mathbb{E}[h'_n(z, Z_{1:m})]$. Note that $\tilde{h}'_n(Z_0)$ has expectation 0.

By Cauchy–Schwarz, we have

$$
|\hat{\sigma}_{n,\text{out,approx},1}^2 - \hat{\sigma}_{n,\text{out,approx},2}^2| \leq \Delta_2 + 2\sqrt{\Delta_2} \hat{\sigma}_{n,\text{out,approx},2}
$$

for the error term

$$
\Delta_2 \approx \frac{1}{n} \sum_{j,j' = 1}^{k} \sum_{i \in B_{j'}, i' \in B_{j'}} \frac{1}{2}(\tilde{h}'_n(Z_i) - \tilde{h}'_n(Z_{i'}))^2 + \frac{1}{n} \sum_{j,j' = 1}^{k} \sum_{i \in B_{j'}, i' \in B_{j'}} (\tilde{h}'_n(Z_{i'}) - \tilde{h}'_n(Z_{i'}))^2
$$

where we have used Jensen’s inequality in the final display.

Controlling the error $\Delta_2$ We will control the error term $\Delta_2$. By the bound (J.4) and the conditional Efron-Stein inequality (Lemma 1), we have

$$
\mathbb{E}[\Delta_2] \leq 2\frac{m}{2} \gamma_{ms}(h'_n) = m \gamma_{\text{loss}}(h_n).
$$

(J.5)

Controlling the error $\hat{\sigma}_{n,\text{out,approx},2}^2 - \sigma_n^2$ To control the error $\hat{\sigma}_{n,\text{out,approx},2}^2 - \sigma_n^2$, we first rewrite $\hat{\sigma}_{n,\text{out,approx},2}$ as

$$
\hat{\sigma}_{n,\text{out,approx},2}^2 = \frac{1}{n} \sum_{j,j' = 1}^{k} \sum_{i \in B_{j'}, i' \in B_{j'}} \frac{1}{2}(\tilde{h}'_n(Z_i) - \tilde{h}'_n(Z_{i'}))^2
$$

$$
= \frac{1}{n} \sum_{i = 1}^{n} (\tilde{h}'_n(Z_i) - \frac{1}{n} \sum_{i' = 1}^{n} \tilde{h}'_n(Z_{i'}))^2
$$

$$
= \frac{1}{n} \sum_{i = 1}^{n} \tilde{h}'_n(Z_i)^2 - \sigma_n^2.
$$

(J.6)

Since $\mathbb{E}[\tilde{h}'_n(Z_i)\tilde{h}'_n(Z_{i'})] = 0$ for all $i, i' \in [n]$ with $i \neq i'$ due to independence, we have

$$
\mathbb{E}\left[(\frac{1}{n} \sum_{i = 1}^{n} \tilde{h}'_n(Z_i))^2\right] = \frac{1}{n} \mathbb{E}[\tilde{h}'_n(Z_0)^2] = \frac{1}{n} \sigma_n^2.
$$

(J.7)

Furthermore,

$$
\mathbb{E}[\left(\frac{1}{n} \sum_{i = 1}^{n} \tilde{h}'_n(Z_i)^2 - \sigma_n^2\right)^2] = \text{Var}(\frac{1}{n} \sum_{i = 1}^{n} \tilde{h}'_n(Z_i)^2) = \frac{1}{n} \text{Var}(\tilde{h}'_n(Z_0)^2) = \frac{1}{n} (\mathbb{E}[\tilde{h}'_n(Z_0)^4] - \sigma_n^4)
$$

by independence. Hence, we have

$$
\mathbb{E}[\left(\hat{\sigma}_{n,\text{out,approx},2}^2 - \sigma_n^2\right)] \leq \sqrt{\frac{1}{n}(\mathbb{E}[\tilde{h}'_n(Z_0)^4] - \sigma_n^4) + \frac{1}{n} \sigma_n^2}.
$$

Putting the pieces together Since each

$$
\frac{1}{2}(\tilde{h}'_n(Z_i, Z_{B_{j'}}) - \tilde{h}'_n(Z_{i'}, Z_{B_{j'}}))^2 \leq \tilde{h}'_n(Z_i, Z_{B_{j'}})^2 + \tilde{h}'_n(Z_{i'}, Z_{B_{j'}})^2,
$$

we have

$$
\mathbb{E}[\hat{\sigma}_{n,\text{out,approx},1}^2] \leq 2\mathbb{E}[\tilde{h}'_n(Z_0, Z_{1:m})^2] = 2\sigma_n^2
$$

29
and hence
\[ E[\sqrt{\Delta_1} \hat{s}_{n,\text{out},\text{approx},1}] \leq \sqrt{E[\Delta_1]E[\hat{s}_{n,\text{out},\text{approx},1}^2]} \leq \sqrt{2(1 + \frac{n}{k})\gamma_{\text{ms}}(h_n)\sigma_n^2} \]
by Cauchy–Schwarz and the bound \( (J.3) \).

Moreover, \( E[\hat{s}_{n,\text{out},\text{approx},2}^2] = (1 - \frac{1}{n})\sigma_n^2 \), hence
\[ E[\sqrt{\Delta_2} \hat{s}_{n,\text{out},\text{approx},2}] \leq \sqrt{E[\Delta_2]E[\hat{s}_{n,\text{out},\text{approx},2}^2]} \leq \sqrt{m\gamma_{\text{loss}}(h_n)(1 - \frac{1}{n})\sigma_n^2} \]
by Cauchy–Schwarz and the bound \( (J.5) \).

Assembling our results with the triangle inequality, we find that
\[ E[|\hat{s}_{n,\text{out}}^2 - \sigma_n^2|] \leq E[|\hat{s}_{n,\text{out},\text{approx},1}^2 - \sigma_n^2|] + E[|\hat{s}_{n,\text{out},\text{approx},1} - \hat{s}_{n,\text{out},\text{approx},2}|]
+ E[|\hat{s}_{n,\text{out},\text{approx},2}^2 - \sigma_n^2|]
\leq E[\Delta_1] + 2E[\sqrt{\Delta_1} \hat{s}_{n,\text{out},\text{approx},1}]
+ E[\Delta_2] + 2E[\sqrt{\Delta_2} \hat{s}_{n,\text{out},\text{approx},2}]
+ \sqrt{\frac{1}{n}(E[h_n'(Z_0)]^2 - \sigma_n^2)} + \frac{1}{n}\sigma_n^2
\leq (1 + \frac{1}{n})\gamma_{\text{ms}}(h_n) + 2\sqrt{2(1 + \frac{n}{k})\gamma_{\text{ms}}(h_n)\sigma_n^2}
+ m\gamma_{\text{loss}}(h_n) + 2\sqrt{m\gamma_{\text{loss}}(h_n)(1 - \frac{1}{n})\sigma_n^2}
+ \sqrt{\frac{1}{n}(E[h_n'(Z_0)]^2 - \sigma_n^2)} + \frac{1}{n}\sigma_n^2
\]
as advertised.

We showed in the proof of Theorem 9 that \( \frac{1}{n}\sum_{i=1}^{n} \tilde{h}_n(Z_i)^2 / \sigma_n^2 \xrightarrow{L^1} 1 \) whenever the sequence of
\( (\tilde{h}_n(Z_0) - E[\tilde{h}_n(Z_0)])^2 / \sigma_n^2 \rightarrow \tilde{h}_n'(Z_0)^2 / \sigma_n^2 \) is uniformly integrable. Thus, with \( (J.6) \) and \( (J.7) \), we get
\[ E[|\hat{s}_{n,\text{out},\text{approx},2}^2 / \sigma_n^2 - 1|] \leq 1/n + o(1), \]
and the final bound advertised
\[ E[|\hat{s}_{n,\text{out}}^2 - \sigma_n^2|] \leq (1 + \frac{n}{k})\gamma_{\text{ms}}(h_n) + 2\sqrt{2(1 + \frac{n}{k})\gamma_{\text{ms}}(h_n)\sigma_n^2}
+ m\gamma_{\text{loss}}(h_n) + 2\sqrt{m\gamma_{\text{loss}}(h_n)(1 - \frac{1}{n})\sigma_n^2}
+ \frac{1}{n}\sigma_n^2 + o(\sigma_n^2). \]

By the bound \( (J.1) \), \( (\hat{s}_{n,\text{out}}^2 - \sigma_n^2)/\sigma_n^2 \xrightarrow{L^1} 0 \), i.e. \( \hat{s}_{n,\text{out},\text{approx}} / \sigma_n \xrightarrow{L^1} 1 \), if the sequence of
\( (\tilde{h}_n(Z_0) - E[\tilde{h}_n(Z_0)])^2 / \sigma_n^2 \) is uniformly integrable, \( \gamma_{\text{loss}}(h_n) = o(\sigma_n^2 / n) \) and \( \gamma_{\text{ms}}(h_n) = o(\min(\frac{k\sigma_n^2}{n}, \frac{k\sigma_n^2}{n})) \).

By noticing that \( \hat{s}_{n,\text{out}}^2 / \sigma_n^2 \rightarrow 1 \) when \( \gamma_{\text{loss}}(h_n) = o(\sigma_n^2 / n) \) thanks to Proposition 2, the last condition becomes \( \gamma_{\text{ms}}(h_n) = o(k\sigma_n^2 / n) \). Therefore, Theorem 5 follows from Theorem 11.

## K Experimental Setup Details

Here, we provide more details about the experimental setup of Section 5.

### K.1 General experimental setup details

**Learning algorithms and hyperparameters** To illustrate the performance of our confidence intervals and tests in practice, we carry out our experiments with a diverse collection of popular learning algorithms. For classification, we use the xgboost XGBRFClassifier with \texttt{n_estimators=100}, \texttt{subsample=0.5} and \texttt{max_depth=1}, the scikit-learn MLPClassifier neural network with \texttt{hidden_layer_sizes=(8,4,)} defining the architecture and \texttt{alpha=1e2}, and the scikit-learn \( L^2 \)-penalized LogisticRegression with \texttt{solver='lbfgs'} and \texttt{C=1e-3}. For regression, we use the xgboost XGBRFRegressor with \texttt{n_estimators=100},

30
subsample=0.5 and max_depth=1, the scikit-learn MLPRegressor neural network with hidden_layer_sizes=(8,4,) defining the architecture and alpha=1e2, and the scikit-learn Ridge regressor with alpha=1e6. The random forest max_depth hyperparameter and neural network, logistic, and ridge $\ell^2$ regularization strengths were selected to ensure the stability of each algorithm. All remaining hyperparameters are set to their defaults, and we set random seeds for all algorithms’ random states for reproducibility. We use scikit-learn [43] version 0.22.1 and xgboost [17] version 1.0.2.

**Training set sample sizes $n$** For both datasets, we work with the following training set sample sizes $n$: 700, 1,000, 1,500, 2,300, 3,400, 5,000, 7,500, 11,000. Up to some rounding, this corresponds to a geometric sequence with growth rate 50%.

**Details on the Higgs dataset** The target variable has value either 0 or 1 and there are 28 features. We initially shuffle the rows of the dataset uniformly at random and then, starting at the 5,000,001-th instance, we take 500 consecutive chunks of the largest sample size, that is 11,000. For each $n$, we take the first $n$ instances of these 500 chunks to play the role of our 500 independent replications of size $n$. The features are standardized during training in the following way: for each iteration of $k$-fold CV ($k=10$ here), we rescale the validation fold and the remaining folds, used as training, with the mean and standard deviation of the training data. The features for the training folds then have mean 0 and variance 1.

**Details on the FlightsDelay dataset** To avoid the temporal dependence issues inherent to time series datasets, we treat the complete FlightsDelay dataset as the population and thus process it differently from the Higgs dataset. For this dataset, we predict the signed log transform ($y \mapsto \text{sign}(y) \log(1 + |y|)$; this addressed the very heavy tails of $y$ on its original scale) of the delay at arrival using 4 features: the scheduled time of the journey from the origin airport to the destination airport (taxi included), the distance between the two airports, the scheduled time of departure in minutes (converted from a time to a number between 0 and 1,439) and the airline operating the plane (that we one-hot encode). We drop the instances that have missing values for at least one of these variables. Then, we perform 500 times the sampling with replacement of 11,000 points, that is the largest sample size. For each $n$, we take the first $n$ instances of these 500 chunks to play the role of our 500 independent replications of size $n$. The features are standardized during training in the same way we do for the Higgs dataset.

**Computing target test errors** We form a surrogate ground-truth estimate of the target test errors using the first 5,000,000 instances for the classification dataset and the whole data for the regression dataset. As an illustration, for our method where the target test error is the $k$-fold test error $R_n = \frac{1}{n} \sum_{j=1}^{10} \sum_{i \in B_j} \mathbb{E}[h_n(Z_i, Z_{B_{j}}) \mid Z_{B_j}] = \frac{1}{n} \sum_{j=1}^{10} \mathbb{E}[h_n(Z_0, Z_{B_{j}}) \mid Z_{B_j}]$, we use these instances to compute the $k$ conditional expectations by a Monte Carlo approximation. Practically, for each training set $Z_{B_j}$, we compute the average loss on these instances of the fitted prediction rule learned on $Z_{B_j}$. Then, we evaluate the CIs and tests constructed from the 500 training sets of varying sizes $n$ sampled from the datasets.

**Random seeds** Seeds are set in the code to ensure reproducibility. They are used for the initial random shuffling of the datasets, the sampling with replacement for the regression dataset, the random partitioning of samples in each replication, and the randomized algorithms.

**K.2 List of procedures**

In our numerical experiments, we compare our procedures with the most popular alternatives from the literature. For each procedure, we give its target test error $R_n$, the estimator $\hat{R}_n$ of this target, the variance estimator $\hat{\sigma}^2_n$, the two-sided CI used in Section 5.1, and the one-sided test used in Section 5.2.

In the following, $q_{\nu}$ is the $\alpha$-quantile of a standard normal distribution and $t_{\nu,\alpha}$ is the $\alpha$-quantile of a $t$ distribution with $\nu$ degrees of freedom.
1. Our 10-fold CV CLT-based test, with $\hat{\sigma}_n$ being either $\hat{\sigma}_{n,in}$ (Theorem 4) or $\hat{\sigma}_{n,out}$ (Theorem 5). The curve with $\hat{\sigma}_{n,in}$ is not displayed in our plots since the results are almost identical to those for $\hat{\sigma}_{n,out}$ and the curves are overlapping.

- Target test error: $R_n = \frac{1}{10} \sum_{j=1}^{10} \mathbb{E}[h_n(Z_0, Z_{B_j}) \mid Z_{B_j}]$.
- Estimator: $\hat{R}_n = \frac{1}{n} \sum_{i=1}^{n} \sum_{j \in B_i} h_n(Z_i, Z_{B_j})$.
- Variance estimator: $\hat{\sigma}^2_n$, either $\hat{\sigma}^2_{n,in}$ or $\hat{\sigma}^2_{n,out}$.
- Two-sided $(1-\alpha)$-CI: $\hat{R}_n \pm q_{1-\alpha/2}\hat{\sigma}_n/\sqrt{n}$.
- One-sided test: REJECT $H_0 \iff \hat{R}_n < q_{\alpha}\hat{\sigma}_n/\sqrt{n}$.

2. Hold-out test described, for instance, in Austern and Zhou [5, Eq. (17)].

- Variance estimator: $\hat{\sigma}$.
- Target test error: $\hat{\sigma}$.
- Two-sided $(1-\alpha)$-CI: $\hat{R}_n \pm q_{1-\alpha/2}\hat{\sigma}_n/\sqrt{n}$.
- One-sided test: REJECT $H_0 \iff \hat{R}_n < q_{\alpha}\hat{\sigma}_n/\sqrt{n}$.

3. Cross-validated t-test of Dietterich [21], 10 folds.

- Target test error: $R_n = \mathbb{E}[h_n(Z_0, Z_S) \mid Z_S]$, where $S$ is a subset of size $\lfloor n(1-1/10) \rfloor$ of $\lfloor n \rfloor$. Since we already have a partition for our 10-fold CV, we can use the first fold $B_1$ for $S$.
- Estimator: $\hat{R}_n = \frac{1}{|S|} \sum_{i \in S} h_n(Z_i, Z_S)$.
- Variance estimator: $\hat{\sigma}^2_n = \frac{1}{|S|} \sum_{i \in S} (h_n(Z_i, Z_S) - \hat{R}_n)^2$.
- Two-sided $(1-\alpha)$-CI: $\hat{R}_n \pm t_{10-1,1-\alpha/2}\hat{\sigma}_n/\sqrt{10}$.
- One-sided test: REJECT $H_0 \iff \hat{R}_n < t_{10-1,\alpha}\hat{\sigma}_n/\sqrt{10}$.

4. Repeated train-validation t-test of Nadeau and Bengio [42], 10 repetitions of 90-10 train-validation splits.

- Target test error: $R_n = \frac{1}{10} \sum_{j=1}^{10} \mathbb{E}[h_n(Z_0, Z_{S_j}) \mid Z_{S_j}]$, where for any $j \in [10]$, $S_j$ is a subset of size $\lfloor n(1-1/10) \rfloor$ of $\lfloor n \rfloor$, and these 10 subsets are chosen independently.
- Estimator: $\hat{R}_n = \frac{1}{m_{-j}} \sum_{j=1}^{10} p_j$, where $p_j \triangleq \frac{1}{|S_j|} \sum_{i \in S_j} h_n(Z_i, Z_{S_j})$.
- Variance estimator: $\hat{\sigma}^2_n = \frac{1}{m_{-j}} \sum_{j=1}^{10} (p_j - \hat{R}_n)^2$.
- Two-sided $(1-\alpha)$-CI: $\hat{R}_n \pm t_{10-1,1-\alpha/2}\hat{\sigma}_n/\sqrt{10}$.
- One-sided test: REJECT $H_0 \iff \hat{R}_n < t_{10-1,\alpha}\hat{\sigma}_n/\sqrt{10}$.

5. Corrected repeated train-validation t-test of Nadeau and Bengio [42], 10 repetitions of 90-10 train-validation splits.

- Target test error: $R_n = \frac{1}{10} \sum_{j=1}^{10} \mathbb{E}[h_n(Z_0, Z_{S_j}) \mid Z_{S_j}]$, where for any $j \in [10]$, $S_j$ is the same as in the previous procedure.
- Estimator: $\hat{R}_n = \frac{1}{m_{-j}} \sum_{j=1}^{10} p_j$, where $p_j$ is the same as in the previous procedure.
- Variance estimator: $\hat{\sigma}^2_n = (\frac{1}{10} + \frac{0.1}{10-1}) \frac{10}{m_{-j}} \sum_{j=1}^{10} (p_j - \hat{R}_n)^2$.
- Two-sided $(1-\alpha)$-CI: $\hat{R}_n \pm t_{10-1,1-\alpha/2}\hat{\sigma}_n/\sqrt{10}$.
- One-sided test: REJECT $H_0 \iff \hat{R}_n < t_{10-1,\alpha}\hat{\sigma}_n/\sqrt{10}$.

6. 5 × 2-fold CV test of Dietterich [21].

- Target test error: $R_n = \frac{1}{4} \sum_{j=1}^{5} \frac{1}{2} \mathbb{E}[h_n(Z_0, Z_{B_{1,j}}) \mid Z_{B_{1,j}}] + \mathbb{E}[h_n(Z_0, Z_{B_{2,j}}) \mid Z_{B_{2,j}}]$, where for any $j \in [5]$, $\{B_{1,j}, B_{2,j}\}$ is a partition of $\lfloor n \rfloor$ into 2 folds of size $n/2$, and these 5 partitions are chosen independently.
- Estimator: $\hat{R}_n = \frac{1}{|B_{1,j}|} \sum_{i \in B_{1,j}} h_n(Z_i, Z_{B_{1,j}})$.
• Variance estimator: \( \hat{\sigma}_n^2 = \frac{1}{k} \sum_{i=1}^{n} s_i^2 \), where \( s_i^2 \triangleq (p_{1,j} - \bar{p}_j)^2 + (p_{2,j} - \bar{p}_j)^2 \) with \( \bar{p}_j \triangleq (p_{1,j} + p_{2,j})/2 \) and \( p_{k,j} \triangleq \frac{1}{|B_{k,j}|} \sum_{i \in B_{k,j}} h_n(Z_i, Z_{B_k,j}) \) for \( k \in [2], j \in [5] \).

• Two-sided \((1 - \alpha)\)-CI: \( \hat{R}_n \pm t_{\nu}^{1-\alpha/2} \hat{\sigma}_n \).

• One-sided test: REJECT \( H_0 \leftrightarrow \hat{R}_n < t_{\nu,\bar{\alpha}} \hat{\sigma}_n \).

**K.3 Leave-one-out cross-validation**

As a simple demonstration of our LOOCV CLT-based procedure, explained in Section 5.4, we follow the ridge regression experimental setup described in Appendix K.1 except that we do not standardize the features. In our LOOCV CLT-based procedure, the quantities of interest are the following.

• Target test error: \( \hat{R}_n = \frac{1}{n} \sum_{i=1}^{n} \mathbb{E}[h_n(Z_0, Z_{(i)\cdot})] \).

• Estimator: \( \hat{\hat{R}}_n = \frac{1}{n} \sum_{i=1}^{n} h_n(Z_i, Z_{(i)\cdot}) \) computed thanks to the Sherman–Morrison–Woodbury formula for ridge regression, or approximate LOOCV estimator for other algorithms.

• Variance estimator: \( \hat{\sigma}_{n,\text{out}}^2 \) with \( k = n \) folds.

• Two-sided \((1 - \alpha)\)-CI: \( \hat{R}_n \pm q_{1-\alpha/2} \hat{\sigma}_{n,\text{out}} / \sqrt{n} \).

• One-sided test: REJECT \( H_0 \leftrightarrow \hat{R}_n < q_{\alpha} \hat{\sigma}_{n,\text{out}} / \sqrt{n} \).

We explain here how the Sherman–Morrison–Woodbury formula can be used to efficiently compute the individual losses \( h_n(Z_i, Z_{(i)\cdot}) \), and therefore \( \hat{R}_n \), as well as \( \hat{\sigma}_{n,\text{out}} \), and the loss on the instances used to form a surrogate ground-truth estimate of the target error \( \hat{R}_n \). Let \( X \in \mathbb{R}^{n \times p} \) be the matrix of predictors, whose \( i \)-th row is \( x_i \), and \( Y \in \mathbb{R}^n \) be the target variable. The weight vector estimate \( \hat{w} \) minimizes \( \min_{w \in \mathbb{R}^p} \| Y - Xw \|_2^2 + \lambda \| w \|_2^2 \), and is given by the closed-form formula

\[
\hat{w} = (X^\top X + \lambda I_p)^{-1} X^\top Y.
\]

We precompute \( M \triangleq (X^\top X + \lambda I_p)^{-1} \) and \( v \triangleq X^\top Y \), that satisfy \( \hat{w} = Mv \). Suppose that we have an additional set with covariate matrix \( \tilde{X} \) and target variable \( \tilde{Y} \), representing the instances used to form a surrogate ground-truth estimate of \( R_n \). We also precompute \( q \triangleq \tilde{X}\hat{w} \) and \( A \triangleq \tilde{X}M \).

For the datapoint \( i \), let \( X^{(-i)} \) denote \( X \) without its \( i \)-th row and \( Y^{(-i)} \) denote \( Y \) without its \( i \)-th element. Let \( M_i \triangleq (X^{(-i)}\top X^{(-i)} + \lambda I_p)^{-1}, v_i \triangleq X^{(-i)}\top Y^{(-i)} \) and \( w_i \triangleq M_iv_i \). We can efficiently compute \( M_i \) from \( M \) based on the Sherman–Morrison–Woodbury formula.

\[
M_i = (X^{(-i)}\top X^{(-i)} + \lambda I_p)^{-1} = (X^\top X - x_i x_i^\top + \lambda I_p)^{-1} = M - Mx_i x_i^\top M/(-1 + h_i),
\]

where \( h_i \triangleq x_i^\top Mx_i \).

We can compute \( v_i \) from \( v \), with \( v_i = X^{(-i)}\top Y^{(-i)} = v - x_i y_i \).

Therefore, \( w_i = M_iv_i = (M - Mx_i x_i^\top M(-1 + h_i)^{-1})(v - x_i y_i) = \hat{w} + Mx_i(\langle \hat{w}, x_i \rangle - y_i)/(1 - h_i) \) can be computed without fitting any additional prediction rule. Then \( h_n(Z_i, Z_{(i)\cdot}) = (y_i - \langle w_i, x_i \rangle)^2 \), and we use them to compute \( \hat{\hat{R}}_n \) and \( \hat{\sigma}_{n,\text{out}} \). To make predictions for the covariate matrix \( \hat{\tilde{X}} \), we efficiently compute \( \tilde{X}w_i \) as

\[
\tilde{X}w_i = \tilde{X}\hat{w} + \tilde{X}Mx_i(\langle \hat{w}, x_i \rangle - y_i)/(1 - h_i) = q + Ax_i(\langle \hat{w}, x_i \rangle - y_i)/(1 - h_i),
\]

and \( \frac{1}{N} \| \tilde{Y} - \tilde{X}w_i \|_2^2 \) is an estimate of \( \mathbb{E}[h_n(Z_0, Z_{(i)\cdot})] | Z_{(i)\cdot}] \), where \( N \) is the size of the whole dataset. An estimate of \( R_n \) is then \( \frac{1}{n} \sum_{i=1}^{n} \frac{1}{N} \| \tilde{Y} - \tilde{X}w_i \|_2^2 \).
L Additional Experimental Results

This section reports the additional results of the experiments described in Section 5.

L.1 Additional confidence interval results

The remaining results of the experiments described in Section 5.1 are provided in Figs. 4 and 5. We remind the reader that each mean width estimate is displayed with a ± 2 standard error confidence band, while the confidence band surrounding each coverage estimate is a 95% Wilson interval. For all learning tasks, all procedures except the repeated train-validation t interval provide near-nominal coverage, and our CV CLT intervals provide the smallest widths.

![Figure 4: Test error coverage (left) and width (right) of 95% confidence intervals (see Section 5.1). Top: \(\ell^2\)-regularized logistic regression classifier. Middle: Random forest classifier. Bottom: Neural network classifier.](image)

L.2 Additional testing results

The remaining results of the testing experiments described in Section 5.2 are provided in Figs. 6 to 11. In contrast to Section 5.2, where we identified the algorithm \(A_1\) that more often has smaller test error across our simulations and displayed the power of the level \(\alpha = 0.05\) test of \(H_1: \text{Err}(A_1) < \text{Err}(A_2)\) and the size of the level \(\alpha = 0.05\) test of \(H_1: \text{Err}(A_2) < \text{Err}(A_1)\), here we plot the size and power of the \(H_1: \text{Err}(A_1) < \text{Err}(A_2)\) test in the left column of each figure and the size and power of the \(H_1: \text{Err}(A_2) < \text{Err}(A_1)\) test in the right column. We remind the reader that the confidence band surrounding each power or size estimate is a 95% Wilson interval and that we added caps to the error bars to help distinguish superimposed error bars. We also remind the
reader that for all procedures we only display points based on at least 25 replications under the null for size plots and at least 25 replications under the alternative for power plots.

L.3 Importance of stability

In this section, we provide the figures (Figs. 12 to 14) and experimental details supporting the importance of stability experiment of Section 5.3. Compared to the chosen hyperparameters described in Appendix K, for this example, we used the default value of max_depth for XGBRFRegressor, that is 6, and the default value of alpha for MLPRegressor, that is 1e-4. For Figs. 14a and 14b, we obtain an estimate of $\sigma_n^2 = \text{Var}(\hat{h}_n(Z_0))$ by computing a Monte Carlo approximation of $\hat{h}_n(Z_0) = \mathbb{E}[h_n(Z_0, Z_1:n) | Z_0]$ for each of 10,000 $Z_0$ values and then reporting the empirical variance of these 10,000 approximated values. For each value of $Z_0$ we employ the Monte Carlo approximation of

$$
\hat{h}_n(Z_0) \approx \frac{1}{500} \sum_{\ell=1}^{500} \frac{1}{k} \sum_{j=1}^{k} h_n(Z_0, Z_{\ell:j}^{(f)})
$$

where $(Z_{1:n}^{(f)})_{f=1}^{500}$ are the 500 datasets of size $n$ described in Appendix K.
Figure 6: Size (top) and power (bottom) of level-0.05 tests for improved test error (see Section 5.2). **Left:** Testing $H_1$: neural network improves upon $\ell^2$-regularized logistic regression classifier. **Right:** Testing $H_1$: $\ell^2$-regularized logistic regression classifier improves upon neural network.

Figure 7: Size (top) and power (bottom) of level-0.05 tests for improved test error (see Section 5.2). **Left:** Testing $H_1$: $\ell^2$-regularized logistic regression classifier improves upon random forest. **Right:** Testing $H_1$: random forest improves upon $\ell^2$-regularized logistic regression classifier.
Figure 8: Size (top) and power (bottom) of level-0.05 tests for improved test error (see Section 5.2). **Left:** Testing $H_1$: neural network classifier improves upon random forest. **Right:** Testing $H_1$: random forest classifier improves upon neural network.

Figure 9: Size (top) and power (bottom) of level-0.05 tests for improved test error (see Section 5.2). **Left:** Testing $H_1$: ridge regression improves upon random forest. **Right:** Testing $H_1$: random forest improves upon ridge regression.
Figure 10: Size (top) and power (bottom) of level-0.05 tests for improved test error (see Section 5.2). **Left:** Testing $H_1$: neural network improves upon ridge regression. **Right:** Testing $H_1$: ridge regression improves upon neural network.

Figure 11: Size (top) and power (bottom) of level-0.05 tests for improved test error (see Section 5.2). **Left:** Testing $H_1$: neural network regression improves upon random forest. **Right:** Testing $H_1$: random forest regression improves upon neural network.
Figure 12: **Impact of instability** on size (left) and power (right) of level-0.05 tests for improved test error (see Section 5.3). Testing $H_1$: less stable neural network regression improves upon less stable random forest.

Figure 13: **Impact of instability** on test error coverage (top) and width (bottom) of 95% confidence intervals (see Section 5.3). **Left:** Less stable neural network regression. **Right:** Less stable random forest regression.
Figure 14: **Impact of instability** on variance of $\frac{\sqrt{n}}{\sigma_n}(\hat{R}_n - R_n)$ (see Section 5.3). **Left:** $h_n(Z_0, Z_B) = (Y_0 - \hat{f}_1(X_0; Z_B))^2 - (Y_0 - \hat{f}_2(X_0; Z_B))^2$ for neural network and random forest prediction rules, $\hat{f}_1$ and $\hat{f}_2$. As predicted in Theorems 1 and 2, the variance is close to 1 when $h_n$ is stable, but the variance can be much larger when $h_n$ is unstable. **Right:** $h_n(Z_0, Z_B) = (Y_0 - \hat{f}(X_0; Z_B))^2$ for neural network or random forest prediction rule, $\hat{f}$. The same destabilized algorithms produce relatively stable $h_n$ in the context of single algorithm assessment, as the variance parameter $\sigma_n^2 = \text{Var}(h_n(Z_0))$ is larger.
