REMARKS ON FREE FIELD REALIZATION OF $SL(2, \mathbb{R})_k/U(1) \times U(1)$
WZNW MODEL

GASTÓN E. GIRIBET AND DANIEL E. LÓPEZ-FOGLIANI

Abstract. Free field representations of vertex algebra in $SL(2, \mathbb{R})_k/U(1) \times U(1)$ WZNW model are constructed by considering a twisted version of the Bershadsky-Kutasov free field description of discrete states in the two-dimensional black hole CFT. These correspond to conjugate representations describing primary states in the model on $SL(2, \mathbb{R})/U(1) \times U(1)$. A particular evaluation of these leads to identities due to the spectral flow symmetry of $sl(2)_k$ algebra.

The computation of correlation functions violating the winding number conservation is discussed and, as an application, these are compared with analogous results known for the sine-Liouville theory. Exact agreement is observed between both analytic structures.

1. Introduction

Among many interesting applications of this model, the $SL(2, \mathbb{R})_k/U(1) \times U(1)$ WZNW can be identified as the CFT describing the string theory in $AdS_3$.

In reference [1], the free field realization of string theory in $AdS_3$ was studied in terms of the WZNW model formulated on this manifold, and it was shown there how the winding sectors of Hilbert space naturally appear in such construction. The Coulomb gas integral representation was analyzed in this context and used to explicitly compute correlation functions [2] describing string scattering processes. The free field representation of $SL(2, \mathbb{R})_k$ WZNW model was also studied in [3]; see references therein.

Here, with the intention to advance in the understanding of the free field representation of this non-rational CFT, we present an extension of the results of references [1] [2] [4]. Precisely speaking, the points treated here continue our previous study [1] [2] about the Dotsenko integral representation of correlation functions in Wess-Zumino-Novikov-Witten (WZNW) model formulated on the product between the quotient $SL(2, \mathbb{R})/U(1)$ (which describes string theory on the euclidean version of two-dimensional black hole [6]) and a time-like free $U(1)$ boson.

To begin, let us motivate the topic by mentioning that the interest of this particular conformal model is mainly based in the following two aspects: First, the successful description of correlation functions in $AdS_3$ string theory in terms of the free field representation, which nourishes the intention to study the feasibility and fruitfulness of such formalism in this and other conformal models in more detail. Secondly, the conformal theory on the product $SL(2, \mathbb{R})/U(1) \times U(1)$, by itself, turns out to be closely related with many other interesting systems in string theory: e.g. it is related with the $\mathcal{N}=2$ Kazama-Suzuki coset models, with the $c=1$ conformal theory and, of course, with black hole geometries in two and three dimensions. See for instance the interesting works on related subjects [11] [12].

Pre-print numbers: FTUAM 04/09, IFT-UAM/CSIC-04017.
As mentioned, the interactions of winding\(^1\) strings in AdS\(_3\) (accordingly with the construction proposed in [8]) were described [2] in terms of the WZNW model formulated on the mentioned product manifold. More precisely, it was shown how the correlation functions can be computed in terms of the free field description of this theory beyond the near boundary limit by means of the analytic continuation of certain integral equations (see also [7]). Three-point functions representing string scattering processes violating the winding number conservation were explicitly calculated for the cases where two of the three interacting states were represented by highest-weight vectors of the SL\((2,\mathbb{R})\). In fact, one of the preliminary goals of this note is to extend the free field computation presented in [2] in order to observe how the group theoretical factor, which parametrizes the discrete representations of SL\((2,\mathbb{R})\), appears in a more general case. This will enable us to study the relation existing with analogous correlators presented in the literature for the case of sine-Liouville conformal field theory [4].

This note is organized as follows: First, in section 2, we briefly review the results of reference [1, 2] and, consequently, we extend in section 3 the conjugate representations of \(\hat{sl}(2)_k\) vertex algebra in order to describe, for example, the \(m\)-dependent group theoretical factor standing in the computation of three-point function for winding violating processes. We remark important aspects of the Dotsenko conjugate representations which were not addressed in our previous works in the subject. Besides, in order to avoid redundances, we refer to the mentioned works for the details.

The free field realization leading to the integral representation of two and three-point correlators in WZNW model formulated on SL\((2,\mathbb{R})/U(1)\times U(1)\) is reviewed and, consequently, previous discussions about the explicit examples of realizations of the \(\hat{sl}(2)_k\) operator algebra are substantially extended. For instance, one of our main goals is to show that the free field representation of the simplest discrete states in the two-dimensional black hole admits an extension which leads to construct conjugate representations of Kac-Moody primary states on the product manifold SL\((2,\mathbb{R})/U(1)\times U(1)\).

Then, the computations of two and three-point functions are revisited by using this conjugate representations for vertex operators. Explicit formula for winding violating scattering processes is written down. As an application, we study in section 5 the construction of correlators representing scattering processes violating the winding number conservation in sine-Liouville theory, which has been conjectured to be a dual model of the string theory on the cigar manifold SL\((2,\mathbb{R})/U(1)\). This will enable us to work out an extension of the comparison effectuated in [4] regarding the pole structure of both sine-Liouville model and the non-compact WZNW theory. We show here that the case of violating winding number (let us denote it \(\delta\omega = 1\)) in both conformal models presents similar degree of agreement as the comparison previously effectuated in [4] for the particular (conservative) case \(\delta\omega = 0\). Then, the agreement between the analytic structure of both CFT’s at the level of three-point correlators seems to be exact. The group theoretical factor arising in the formula for WZNW model and the integration over the zero-modes of sine-Liouville are crucial points for asserting such agreement.

---

\(^1\)We will use the name of winding strings to refer to the spectral flow degree of freedom, even though its geometrical meaning is not strictly a winding number for the short string states.
2. Free field representation

This section and the following are devoted to a discussion on the free field representation of $\text{sl}(2)_{k}$ vertex operators. We extend the results of references [1] and [2]; we refer to those papers for the details.

2.1. The action and conformal field theory. Let us start by reviewing the free field representation of the CFT. In [2], the construction of the conformal model on $SL(2, \mathbb{R})/U(1) \times U(1)$ was achieved by means of the realization of the coset manifold $SL(2, \mathbb{R})/U(1)$ presented in the quoted references [13] and [14]. The strategy of those works was to realize the theory formulated on the $SL(2, \mathbb{R})/U(1)$ black hole by introducing an additional space-like bosonic field $X(z)$ describing the $U(1)$ subgroup which, combined with a $(b,c)$ ghost system of spin $(1,0)$, allows to gauge out the Cartan element. Our construction [1] includes a new time-like scalar field $T(z)$ in order to describe the product space $SL(2, \mathbb{R})/U(1) \times U(1)$ which naturally leads to parametrize the winding sectors of the Hilbert space of string theory on $AdS_3$. This auxiliary $U(1)$ factor turns out to be useful to realize the theory on the coset in terms of a convenient free field representation.

Then, the (quantum corrected) action of the conformal model combines the non-linear $\sigma$-model yielding from string theory on the $AdS$ background configuration with the inclusion of these auxiliary free fields; namely

\[ S_1 = \frac{1}{4\pi} \int d^2z \left( \frac{1}{2} \partial\phi \bar{\partial}\phi - \sqrt{\frac{2}{k-2}} R\phi + \beta \bar{\partial}\gamma + \bar{\beta} \partial\gamma + \partial X \bar{\partial} X - \partial T \bar{\partial} T \right) + S_I \]

where\(^2\)

\[ S_I = \frac{M}{4\pi} \int d^2z \mathcal{L}_I(z, \bar{z}), \quad \mathcal{L}_I = \beta \bar{\beta} e^{-\sqrt{\frac{k-2}{2k}}\phi} \]

In the Coulomb gas realization of the correlators, the interaction term \(^1\) acts as the insertion of screening operators. The parameter $M$ represents the black hole mass in two dimensions [13, 6], even tough its relevance for physical meaning is only encoded in its sign.

It was demonstrated in [2] that two and three-point correlation functions defined by this action exactly agree with the analogous computation effectuated by replacing the interaction term $S_I$ by

\[ \tilde{S}_I = \frac{\tilde{M}}{4\pi} \int d^2z (\mathcal{L}_I(z, \bar{z}))^{k-2} \]

if certain precise relation between the parameters $M$ and $\tilde{M}$ holds (see also [15]).

This equality reflects a class of duality between strong and weak regimes $(k-2 \leftrightarrow 1/k-2)$, even though it is not an explicit symmetry of the lagrangian formulation of WZNW model, \textit{i.e.} since the background charge (dilaton term) is not manifestly invariant under the replacement $k-2 \rightarrow 1/k-2$; see below. This symmetry seems to be valid for this CFT and it turns out to be an important aspects because of the existence of a similar duality in quantum Liouville field theory. Unlike the theory on $SL(2, \mathbb{R})$, in Liouville CFT the strong-weak duality manifestly appears as a symmetry of the quantum action $S_1 - S_I$, \textit{i.e.} reflected in the interchange between

\(^2\)the contribution due to the $(b, c)$ ghost system is not explicitly written here.
of the relation holding between the parameters $M$ and $\tilde{M}$ can be inferred from the KPZ scaling behavior of the coupling constants; notice that, by performing the global transformation

$$\phi \rightarrow \phi + \phi_0 \quad \gamma \rightarrow e^{-\phi_0} \gamma \quad \beta \rightarrow e^{\phi_0} \beta,$$

which is a symmetry of the free field action $S_1 - S_I$, the following relations are obtained

$$\frac{\delta M}{M} = \frac{1}{k-2} \frac{\delta \tilde{M}}{M}$$

By integrating these, we can write

$$\tilde{M} = f_1(k-2)M^{k-2}$$

for certain function $f_1(k-2)$, which satisfies $\lim_{\epsilon \rightarrow 1} |f_1(\epsilon)| = 1$. A direct computation [2] leads to obtain the exact expression $f_1(x) = \frac{1}{\pi} \gamma (1 - x) (\pi \gamma (x^{-1}))^x$, being $\gamma(x) = \Gamma(x)/\Gamma(1-x)$. This satisfies $f_1^x(x^{-1})f_1(x) = 1$.

If the interaction term (2) is used (instead (1)) to compute the $N$-point correlators as insertions of $s$ screening charges in Coulomb gas prescription, then the divergences in correlation functions (similar to those which yield from the non-compactness of target space in Liouville theory) would appear due to a $\Gamma(-s)$ factor standing in the integration over the zero-mode $\phi_0$. Some of these divergences, those which are located at $\sum_{i=1}^N j_i = k - 3$, are analogous to the pole conditions conjectured in [9] and interpreted as instantonic contributions to $N$-point functions in AdS$_3$. This agreement suggests an identification between this pole structures and the instantonic contributions referred in [9]. Then, this provides us an argument for asserting that, indeed, these poles do occur in $N$-point correlation functions after the integration over the $(x, \bar{x})$ SL$(2, \mathbb{R})$-isospin coordinates.

2.2. **Wakimoto free field representation of $\hat{sl}(2)_k$.** The WZNW theory on $SL(2, \mathbb{R})/U(1) \times U(1)$ admits a realization in terms of free fields$^4$.

The stress-tensor of the conformal model on the product $SL(2, \mathbb{R})/U(1) \times U(1)$ is given by

$$\mathcal{T} = \beta \partial \gamma - \frac{1}{2} (\partial \phi)^2 - \frac{1}{\sqrt{2k-4}} \partial^2 \phi - \frac{1}{2} (\partial X)^2 - b \partial c + \frac{1}{2} (\partial T)^2$$

and the central charge is then given by

$$c = 3 + \frac{6}{k - 2}.$$
It corresponds to the Sugawara stress-tensor, contracted from the $\hat{sl}(2)_k$ Kac-Moody currents
\begin{align}
(6) \quad J^+(z) &= \beta(z)e^{i\sqrt{\frac{2}{k}}(X(z)+T(z))} \\
(7) \quad J^3(z) &= -\beta(z)\gamma(z) - \sqrt{\frac{k-2}{2}}\partial\phi(z) + i\sqrt{\frac{k}{2}}(\partial X(z) + \partial T(z)) \\
(8) \quad J^-(z) &= \left(\beta(z)\gamma^2(z) + \sqrt{2k-4}\gamma(z)\partial\phi(z) + k\partial\gamma(z)\right)e^{-i\sqrt{\frac{2}{k}}(X(z)+T(z))}
\end{align}
and taking into account the contribution of the spin $(1,0)$ auxiliary ghost system; see [2,13,14,17] for details of construction. Thus, the theory admits a representation of the current algebra in terms of free fields; namely an scalar field $\phi$ with background charge, a $(\beta,\gamma)$ ghost system and the two additional free bosons $X$ and $T$. These fields satisfy the following correlators
\[ \langle \phi(z)\partial\phi(w) \rangle = \langle X(z)\partial X(w) \rangle = \langle \partial T(z)T(w) \rangle = \langle \beta(z)\gamma(w) \rangle = \frac{1}{z-w} \]
The vertex operators in this CFT are given by Virasoro primaries $\Phi^{\varepsilon}_{j,m,\bar{m}}$ creating $SL(2,\mathbb{R})_k$ states $|\Phi^{\varepsilon}_{j,m,\bar{m}}\rangle$ by acting on the invariant vacuum $|0\rangle$; namely
\begin{align}
(9) \quad \lim_{z\to 0} \left( \Phi^{\varepsilon}_{j,m,\bar{m}}(z) + R(j,m)\Phi^{\varepsilon}_{-1-j,m,\bar{m}}(z) \right)|0\rangle = |\Phi^{\varepsilon}_{j,m,\bar{m}}\rangle
\end{align}
where
\begin{align}
(10) \quad R(j,m) = B(j) \frac{\Gamma(1+j+m)\Gamma(1+j-m)\Gamma(-2j-1)}{\Gamma(-m-j)\Gamma(m-j)\Gamma(2+2j)}
\end{align}
and where $B(j)$ is given by the two-point function (see below (22)).

The vertex operators in this CFT are given by Virasoro primaries $\Phi^{\varepsilon}_{j,m,\bar{m}}$ creating $SL(2,\mathbb{R})_k$ states $|\Phi^{\varepsilon}_{j,m,\bar{m}}\rangle$ by acting on the invariant vacuum $|0\rangle$; namely
\begin{align}
(11) \quad \Phi^{\varepsilon}_{j,m,\bar{m}} =: \gamma^j_{-m}e^{i\sqrt{\frac{2}{k}}\phi}e^{i\sqrt{\frac{2}{k}}mX}e^{i\sqrt{\frac{2}{k}}(m+\frac{2}{k}\omega)T} : \times h.c.
\end{align}
where $h.c.$ refers to the anti-holomorphic part, which is similar. These operators satisfy the $\hat{sl}(2)_k$ block structure of Kac-Moody primaries, which is encoded in the following operator product expansion
\begin{align}
(12) \quad J^3(z)\Phi^0_{j,m,\bar{m}}(w) &= \frac{m}{(z-w)}\Phi^0_{j,m,\bar{m}}(w) + ... \\
(13) \quad J^\pm(z)\Phi^0_{j,m,\bar{m}}(w) &= \mp j - \frac{m}{(z-w)}\Phi^0_{j,m,\bar{m}}(w) + ... 
\end{align}
And, analogously, operators (9) for generic $\omega$ are actually Kac-Moody primaries with respect to the algebra generated by the currents obtained by acting with the spectral flow automorphism on (10)-(11).

The action of spectral flow\(^5\) on the modes $J_n^a = \frac{1}{2\pi i} \oint dz J^a(z)z^n$ is defined as follows
\[
J_n^+ \rightarrow J_{n+\omega}^+, \quad J_n^3 \rightarrow J_n^3 - \frac{k}{2}\omega \delta_{n,0}
\]

\(^5\)The spectral flow symmetry was studied in different context in the literature; let us mention the interesting works [17].
Then, it is feasible to see that operators (9) have conformal dimension

\[ h_{(j,m)} = -\frac{j(j+1)}{k-2} + \frac{m^2}{k} - \frac{(m+\frac{k}{2}\omega)^2}{k} \]

where \( j \) and \( m \) parametrize the (universal covering of) representations of \( SL(2,\mathbb{R}) \), as usual. This reproduces the spectrum of string theory on \( AdS_3 \), where the angular momentum, the energy and the winding number of string states are given by the quantities \( p = m - \bar{m}, e = m + \bar{m} + k\omega \) and \( \omega \) respectively. It has to be contrasted with the case of the cigar manifold, where the winding modes are characterized by the quantity \( k\omega = m - \bar{m} \) while the difference \( p = m - \bar{m} \) represents the angular momentum in the asymptotic cylinder. The relation between the three-dimensional Anti-de Sitter space and the product between the two-dimensional euclidean black hole and a time-like coordinate was studied in [9] and [20]. The main distinction between \( AdS_3 \) and the cigar geometry consists in the respective dispersion relation between the winding modes and the energy of both models. Actually, the spectrum of the theory on the coset corresponds to the restriction of vanishing energy in \( AdS_3 \).

Notice that the mass-shell condition (14) remains invariant under the transformations \((j, m, \bar{m}, \omega) \rightarrow (j, -m, -\bar{m}, -\omega), (j, m, \bar{m}, \omega) \rightarrow (-1-j, m, \bar{m}, \omega), (j, m, \bar{m}, 0) \rightarrow (j, \mp m, \pm \bar{m}, 0) \) and \((j, j, 0) \rightarrow (-\frac{k}{2} - j, \frac{k}{2} + j, \frac{k}{2} + j, -1)\). These and their compositions correspond to symmetries of the spectrum which are translated into identities between different representations of \( SL(2,\mathbb{R})_k \).

It is clear that by excluding the auxiliary fields \( X \) and \( T \) (or, which is equivalent, by restricting to the sector \( \omega = 0 \)) in the free field realization of \( J^a \) one finds the standard Wakimoto representation of \( sl(2)_k \). With the purpose to make the \( sl(2,\mathbb{R}) \) structure of representation (6)-(8) more clear, let us consider the functional form \( \Phi_{F_a} = F_d(\gamma)e^{\sqrt{k-2}\gamma} \) and the differential operators

\[ D^+ = \frac{\partial}{\partial \gamma}, \quad D^3 = -\gamma \frac{\partial}{\partial \gamma} + j, \quad D^- = \gamma^2 \frac{\partial}{\partial \gamma} - 2j\gamma \]

which form a representation of \( sl(2) \). Then, by reading the simple pole of the OPE between the currents \( J^a \) and operators \( \Phi_{F_a} \) we can translate the problem of finding a representation \( \Phi_{F_a} \) diagonalizing \( J^a \) into the problem of finding eigenfunctions \( F^a \) of the operators \( D^a \). Then, the solutions to this problem are given by

\[ F_{j,m}^a(\gamma) = \gamma^{j-m}, \quad F_{j,m}^\pm(\gamma) = \gamma^{j+m}e^{\pm m\gamma} \]

where \( F_{j,m}(\gamma) \) corresponds to the standard base (11).

3. Conjugate Representations

3.1. Conjugate representations for \( SL(2,\mathbb{R})_k/U(1) \times U(1) \) WZNW. Conjugate representations should be also considered in order to realize the correlation functions [21]. We state here that these can be constructed by starting from the free field representation of certain discrete states appearing in the string spectrum on two-dimensional black hole manifold (signaled by Bershadsky and Kutasov in reference [14]). In order to do this, it is necessary to perform the change \((j, m, \bar{m}) \rightarrow (-j - \frac{k}{2}, m - \frac{k}{2}, \bar{m} - \frac{k}{2})\) in the states of the coset \( SL(2,\mathbb{R})/U(1) \). This corresponds to a twisting of the states on the product \( SL(2,\mathbb{R})/U(1) \times U(1) \) since the contribution
(i.e. the charge) of the time-like field $T$ remains invariant in this procedure; namely

$$(15) \quad \tilde{\Phi}^\omega_{j,m,\bar{m}} = \frac{(-1)^{m-j}}{\Gamma(m+j+1)} : \beta^{j+m} e^{-\sqrt{\frac{2\pi}{\tau}}(U+\frac{k}{2})} e^{i\sqrt{\frac{\pi}{\tau}}(m-\frac{k}{2})x} e^{i\sqrt{\frac{\pi}{\tau}}(m+\frac{k}{2})U} : \times \ h.c. $$

The normalization here turns out to be the adequate to realize the standard block structure of the $sl(2)_k$ current algebra and, consistently, coincides with the one leading to the group theoretical factor in the correlators. Certainly, it is instructive to verify that (15) satisfies the $sl(2)_k$ block structure of the Kac-Moody primaries of the representation $-1 - j$ with respect of the generators obtained by acting with the spectral flow with parameter $\omega$ on the modes of the currents (1) - (8) (i.e. $\Phi_{-1-j,m,\bar{m}}^\omega \sim \tilde{\Phi}_{j,m,\bar{m}}^\omega$). Moreover, we could also consider, instead (15), a normalization factor $\frac{(-1)^{j+m} B(j)\Gamma(-2j-1)}{\Gamma(m-j)\Gamma(2j+1)}$ yielding to representations yielding to representations yielding to representations yielding to representations.

Restricted to highest-weight states, this correspondence between quantum numbers $j$ and $-\frac{k}{2} - j$ is associated to the fact that the spectral flow automorphism in the $\omega = 1$ sector is closed among the standard representations of $SL(2, \mathbb{R})$ and simply maps highest (lowest)-weight states of the certain representation $j$ in lowest (resp. highest)-weight states of the representation $-\frac{k}{2} - j$.

An important point that deserves to be remarked is the fact that the functional form (15) represents Kac-Moody primary fields indeed, and this generalizes the highest-weight form used in references [1] - [8]. Notice that (15) also includes, as the particular case $\tilde{\Phi}_{-1-j,m,\bar{m}}^\omega \sim \Phi_{j,m,\bar{m}}^\omega$, the representations introduced originally by Dotsenko in [22] in the context of $SU(2)_k$ WZNW model.

Thus, the free field representation of the discrete states in the coset $SL(2, \mathbb{R})_k/U(1)$ admits an extension to the theory on the product $SL(2, \mathbb{R})_k/U(1) \times U(1)$, leading to conjugate representations of Kac-Moody primary states. Indeed, this extension, despite its simplicity, has non trivial implications since, as we know, the discrete states on the coset do not represent Kac-Moody primary fields, but descendents states in the Verma modulo. Actually, the inclusion of the additional scalar fields and the twisting of both $U(1)$ charges turn out to be the reason of the presence of primary operators with such $\beta$-dependent particular functional form for primary states. This is an example of the fact that, even though the theory on $SL(2, \mathbb{R})/U(1)$ and the theory on $SL(2, \mathbb{R})/U(1) \times U(1)$ admit similar realizations, these present very distinctive properties in the spectrum.

We summarize the properties of this conjugate representations $\tilde{\Phi}_{j,m,\bar{m}}^\omega$ in the concluding remarks.

3.2. Spectral flow symmetry and conjugate representations. On the other hand, the identity between different (discrete) representations of $SL(2, \mathbb{R})$, due to the spectral flow symmetry of $sl(2)_k$, allows us to write down a new conjugated representation of highest-weight.

---

6we are omitting here the complex conjugate contribution, which is similar; for instance, operators present a factor $\sim e^{i\sqrt{\frac{\pi}{\tau}}(mX(z) + \bar{m}X_L(z))}$ and analogously for the other free fields, (cf. (37) below). A minor differens appear between holomorphic and anti-holomorphic parts since the phases in the normalization in (15) are $(-1)^{m-j}$ and $(-1)^{-\bar{m}-j}$ respectively.

7which is basically defined by the application $J_n^\pm \to J_{n\pm 1}^\pm$ and $J_0^3 \to J_0^3 - \frac{k}{\tau}$. 

---
states; namely
\[
\hat{\phi}^\omega_{j,j,j} =: \gamma^{-2j-k} e^{-\sqrt{2\pi} (j+\frac{k}{2}) \phi} e^{i \sqrt{2} (j+\frac{k}{2}) X} e^{i \sqrt{2} (j+\frac{k}{2}) \omega} T : \times h.c.
\]
This represents an alternative form for the highest-weight state \(\hat{\phi}^\omega_{j,j,j}\) and should be incorporated to the bestiary studied in [1]. This operator includes the known [5, 9] conjugate representation for the identity
\[
\hat{\phi}^0_{0,0,0} =: \gamma^{-k} e^{-\sqrt{2\pi} k \phi} e^{i \sqrt{2} k X} : \times h.c. , \quad \hat{\phi}^1_{-\frac{k}{2},-\frac{k}{2},-\frac{k}{2}} = \Phi^0_{0,0,0} = 1
\]
And the following relations hold in general
\[
\hat{\phi}^\omega_{-\frac{k}{2},-\frac{k}{2},-\frac{k}{2}} = \hat{\phi}^\omega_{j,j,j}, \quad \hat{\phi}^{-\omega}_{-\frac{k}{2},-\frac{k}{2},-\frac{k}{2}} = \hat{\phi}^{-\omega}_{j,j,j}.
\]
The main observation leading to (18) relies in the fact that the twisting of the \(U(1)\) component (i.e. the difference \(k\omega/2\) between the charges of both free fields \(X\) and \(T\)) and the difference of the signatures of both auxiliary bosons permit to build up the winding \(\omega\)-sectors of \(SL(2, \mathbb{R})_k/\text{U}(1) \times \text{U}(1)\) by assembling these on the sectors \(\omega \in \{-1, 0, +1\}\) of the \(SL(2, \mathbb{R})_k\) factor. Then, the identification between discretes representations of index \(j\) and \(-\frac{k}{2} - j\) turns out to be rigidly translated to generic \(\omega\)-sectors.

3.3. A remark on screening operators and conjugate representations. Conjugate representation [15] also permits us to write a combined interaction term \(S_I + \tilde{S}_I\) composed by [1] and [2] in the following form\(^8\)
\[
S_I + \tilde{S}_I = \frac{M}{4\pi} \int d^2 z \left( \hat{\phi}^{-1}_{-\frac{k}{2},-\frac{k}{2},-\frac{k}{2}} - \Gamma(k-1) f_M(k-2) \hat{\phi}^{-1}_{\frac{k}{2}-2,-\frac{k}{2},-\frac{k}{2}} \right)
\]
where \(f_M(k-2) = f_M(k-2) M^{k-3}\). It is reminiscent of the case of Liouville theory [16], where the (auto)interaction term can be written as a particular evaluation of the functional form of the vertex operators.

In order to extend the analogies with the Liouville model, let us notice that by renormalizing the black hole mass as \(M \to M_{\text{reg}} = M \frac{\Gamma(1 - \frac{1}{k})}{\Gamma(1 - \frac{1}{c-2})}\) and taking the limit \(k \to 3\), the following expression for the (composed) interaction term is obtained
\[
S_I + \tilde{S}_I = \frac{M_{\text{reg}}}{4\pi} \int d^2 z \beta \bar{\beta} e^{-\sqrt{2} \phi} - \sqrt{2} \phi - \log \pi M_{\text{reg}} \beta \bar{\beta}
\]
which is analogous to the \(c = 25\) model, where it has been proved that the Liouville interaction term receives similar corrections [16] (see also [20, 30, 31]). In the \(D = 1\) non-critical string theory it was argued that these non-exponential operators control the anomalous scaling behaviour of random surfaces [32]; thus, the analogous critical behaviour in the \(k = 3\) limit of non-compact WZNW model turns out to be an interesting aspect.

Actually, the critical point \(k = 3\) deserves attention because of the appeareance of particular properties there; e.g. it can be proven that in such case the unitarity bound on the free spectrum implies the locality of the dual conformal field theory formulated on the boundary of \(AdS_3\) space, without the requirement of additional constraints on the external states in the \(N\)-point correlators.

\(^8\)Let us notice that this fact does not mean that the interaction term can be reproduced by using the Wakimoto representation [11] in similar way, as it can be seen from the operator product expansion.
On the other hand, notice that the appearance of a linear term in $\phi$ and a logarithmic term in $\beta \bar{\beta}$ in expression (20) is not a surprise since it is precisely consistent with the fixing $\beta \bar{\beta} \sim \mu_L$ when analysing, for example, the correspondence\(^9\) between the $c = 1$ David-Distler-Kawai theory and the special superconformal coset $\hat{c} = 3$ studied in [33] in the context of the Knizhnik-Polyakov-Zamolodchikov formalism.

The ingredients of this discussion are also reminiscent of the Liouville reduction of WZNW action. Actually, let us briefly remind that by expanding the WZNW theory around a classical solution satisfying $J^+ = k$, $J^- = J^3 = 0$, the Sugawara stress-tensor yielding from (3)-(8) takes a form which, without difficulties, is recognized as the one corresponding to the Liouville stress-tensor, where the Liouville field $\varphi$, the cosmological constant $\mu_L$ and the background charge $Q_L$ are given by

$$\phi = -\sqrt{2} \varphi, \quad \mu_L = kM_{\text{reg}}, \quad Q_L = b + b^{-1}, \quad b^{-2} = k - 2$$

Moreover, (11) and (2) are then identified with the screenings of Liouville theory. The physical interpretation and the geometrical meaning of this reduction were explained\(^10\) in [21, 26]. Then, we see from (20) how the fixing $\beta \bar{\beta} \sim \mu_L$ survives in the limit $b \to 1$.

Then, as an additional corollary, we emphasize that the critical points $k = 3$ and $k = 1$ of the $SL(2, \mathbb{R})_k$ WZNW model, which are the fixed points of the transformation $(k - 2) \to (k - 2)^{-1}$, seem to be an interesting subject for further study; in particular, its connection with the $c = 1$ model.

The class of operators (20) was also studied in reference [28] within the context of the prelogarithmic representation $j = -\frac{1}{2}$ of $sl(2)_k$ algebra.

### 3.4. Two-point correlation function

Now, let us consider the two-point correlation functions, which will be denoted $A_{m_1,m_2}^{j_1,j_2} = \langle \Phi_{j_1,m_1}^{\omega_1}(z_1) \tilde{\Phi}_{j_2,m_2}^{\omega_2}(z_2) \rangle$. A direct calculation of two and three-point functions in terms of Dotsenko-Fateev type integrals on the whole complex plane can be performed with the purpose of obtaining the explicit value for $B(j)$ in (10), being the two-point correlator of the form (see [34])

$$A_{m_1,m_2}^{j_1,j_2} = |z_1 - z_2|^{-4h(j_1,m_1)} \left( R(j_1,m_1) \delta(j_1 - j_2) + \delta(j_1 + j_2 + 1) \right) \delta(m_1 + m_2)$$

where

$$B(j) = (2j + 1) \left( -\frac{\pi M \Gamma(\frac{1}{k - 2})}{\Gamma(1 - \frac{1}{k - 2})} \right)^{2j+1} \Gamma\left(1 - \frac{2j+1}{k - 2}\right) \frac{\Gamma\left(\frac{2j+1}{k - 2}\right)}{\Gamma\left(\frac{2j+1}{k - 2}\right)}$$

The additional overall factor $2j + 1$ standing in (22) was obtained in reference [17]; its presence was remarked in [2] and explained in [9], where it was pointed out that it yields from the direct evaluation of the delta factor $\delta(j_1 - j_2)$ in the two-point function and because of the projective invariance codified in the presence of the factor $\text{Vol}^{-1}(PSL(2, \mathbb{C}))$. In fact, this factor signals the differences existing between continuous and discrete representations of $SL(2, \mathbb{R})$.\(^9\)

\(^9\)Since a logarithmic dependence of the Liouville cosmological constant $\sim \log \mu_L$ arises in the resonant point $2\alpha = b + b^{-1}$ of the Liouville reflection coefficient $R(\alpha)$.

\(^10\)The configuration $J^+ = k$ and the Liouville reduction were studied in detail in references [25, 26, 27]. We will not discuss here the issues of the twisting of stress-tensor $T \to T + \partial J^3$, the BRST cohomology of additional discrete states, the description of the single long string configuration and the relaxation of the constraint $J^3 = 0$; we refer to the mentioned references for the details about these aspects.
The steps of the calculation of expression (22) are analogous to those followed in [2], i.e. the expression

\[
\lim_{\varepsilon \to 0} \frac{\Gamma(\varepsilon)}{\Gamma(\varepsilon - s)} = (-1)^s \Gamma(s + 1)
\]

(for \(s \in \mathbb{N}\)) needs to be considered and combined with the charge symmetry conditions

\[
j_1 - j_2 = s, \quad m_1 + m_2 = 0, \quad \omega_1 + \omega_2 = 0
\]

in order to turn the factor

\[
\frac{\Gamma(s - j_1 + j_2 + \bar{m}_1 + \bar{m}_2) \Gamma(s - j_1 + j_2 + m_1 + m_2)}{\Gamma(-j_1 + m_1) \Gamma(-j_2 + m_2) \Gamma(-j_1 + m_1) \Gamma(-j_2 + m_2)}
\]

coming from the multiplicity of the Wick contractions of the \((\beta, \gamma)\) system, into

\[
\frac{\Gamma(j_1 - m_1 + 1) \Gamma(j_2 - m_2 + 1)}{\Gamma(\bar{m}_1 - j_1) \Gamma(\bar{m}_2 - j_2)}
\]

In (24) and (25), the number \(s\) refers to the total amount of screening operators that needs to be included in order to render the correlation functions non-vanishing.

3.5. Dotsenko prescription and path integral approach. In the consideration above, we used conditions (24), which are defined by the specific conjugate representation of the identity operator

\[
\mathbb{I} \sim \Phi_{0,0,0}^0 =: e^{-\sqrt{\frac{k}{2}}\phi} e^{-i\sqrt{\frac{k}{2}}X} : \times h.c.
\]

The derivation of these conservation laws was detailed in [1] and [22]. These conservation laws are such that the power of \(\gamma\) fields and the power of \(\beta\) fields do coincide for non-vanishing correlators. For instance, this fact enabled the authors of [23] to discuss in detail the correlators containing rational powers of these commuting fields.

Dotsenko prescription. The conjugate representations were originally studied by Dotsenko in the context of \(SU(2)_k\) WZNW model in [22]; and were analyzed in [1] for the 2D black hole geometry. Basically, the construction includes additional elements, namely the conjugate (alternative) representations of vertex operators in the theory. The underlying idea is that each given conjugate representation (let us say \(\Phi_{j,m,m}^\omega\)) induces a non-trivial representation of the identity operator, which is given by a zero-dimension field corresponding to the evaluation \(\Phi_{0,0,0}^0(z) \sim \mathbb{I}\). Then, the balance of the charges of this identity operator under the different fields is translated into particular charge symmetry conditions for the states involved in a non-vanishing correlation function (see the original work [22]). Eventually, this conditions turn out to be conservation laws for non-vanishing scattering amplitudes.

Because of the fact that this construction can seem to be a little abstract up to this point, let us clarify the idea by giving a concise example: Notice that, actually, (27) is not the unique conjugate identity; in fact, other zero-dimension operators can be used as a conjugate representation of the identity, e.g. let us consider

\[
\mathbb{I} \sim \Phi_{-1,0,0}^0 =: \gamma^{-1} e^{-\sqrt{\frac{k}{2}}\phi} : \times h.c.
\]

The consideration of this operator as the conjugate representation of the identity leads to certain charge symmetry conditions (in the spirit of [22]) which precisely coincide with the
conservation laws yielding from the direct integration over the zero-mode\textsuperscript{11} $\phi_0$ in the action $S_1$. This is because the background charge $-\sqrt{2/\kappa}$ of the linear dilaton term in WZNW action coincides with the charge of the conjugate representation $\left(28\right)$ under the field $\phi$. Moreover, the power $-1$ of the field $\gamma$ in $\left(28\right)$ coincides with the difference of powers of fields $\gamma$ and $\beta$ required in order to have non-vanishing correlators, as it is determined by the Riemann-Roch theorem on the sphere. Besides, the zero-dimension operator $\left(28\right)$ induces a proper conjugate representation for the field $\left(11\right)$; and this conjugate version of the field $\Phi^\omega_{j,m,\bar{m}}$ is simply the Weyl reflected operator

$$\Phi^\omega_{j,m,\bar{m}} = \Phi^\omega_{-1-j,m,\bar{m}}$$

and, consequently, we could write $\Phi^0_{0,0,0} = \left(28\right)$. In this sense, operator $\left(28\right)$ could be interpreted as the background charge operator.

Hence, this discussion suggests to try to understand the standard Coulomb gas prescription \cite{[9]} as a particular case which can be included within the framework of this extended Dotsenko-like realization. On the other hand, this permits us to suggest a connection with the arising of zero-dimension operators in the expression for three-point functions in previous computations, see \cite{[35]}. Certainly, operator $\left(28\right)$ can be associated to the leading term in the large $\phi$ regime of certain mode (i.e. $j + 1 = m = \bar{m} = 0$) of the operator

$$\lim_{j \to -1} \sum_{n=0}^{\infty} \frac{(-1)^n e^{-\sqrt{2/\kappa}(n+1)\phi}}{\Gamma(n+1)\Gamma(n+2)} \int d^2x \int dx^3 \frac{\partial^n}{\partial \gamma^n} \delta(\gamma - x) \frac{\partial^n}{\partial \bar{\gamma}^n} \delta(\bar{\gamma} - \bar{x})$$

which is the non-trivial spin $j = -1$ primary field which emerges in the path integral approach to string theory on $AdS_3$. The insertion of this field was considered in order to define the path integral representation of correlation functions\textsuperscript{12}, see \cite{[35]}.

3.6. **Three-point function violating winding number.** Now, let us move to the three-point functions $\mathcal{A}_{j_1,j_2,j_3}^{0,j_1,m_2,m_3}$. Since our principal purpose is to study the three-point correlators describing interaction processes violating the winding number conservation, let us discuss the general form of these non-conservative cases in particular. As mentioned, an explicit formula (cf. \cite{[2]}) for this kind of quantities was given in reference \cite{[2]} for particular cases with two states being of highest or lowest-weight, e.g. $j_2 = -m_2$ and $j_3 = -m_3$. Here, we can generalize that formula by including the operator $\left(14\right)$ in order to consider a generic value for $j_2$ and $m_2$. Thus, by using $\left(23\right)$ and the fact that the following charge symmetry conditions hold

$$j_1 - j_2 - j_3 + \frac{k}{2} = s, \quad m_1 + m_2 + m_3 - \frac{k}{2} = 0, \quad \omega_1 + \omega_2 + \omega_3 + 1 = 0,$$

we find that the three-point functions violating the winding number conservation in one unit is proportional to

$$(-1)^{m_2-m_3} \frac{\Gamma(j_1 - m_1 + 1)\Gamma(j_2 - m_2 + 1)}{\Gamma(-j_1 + m_1)\Gamma(-j_2 + m_2)} \Gamma(j_3 - m_3 + 1)$$

which is the group theoretical factor (cf. \cite{[4]}). In order to write the multiplicity factor yielding from the Wick contraction of the $\left(\beta, \gamma\right)$ system in a simple way, we find convenient to consider

\textsuperscript{11}On the other hand, the consideration of the conjugate identity $\Phi^0_{0,0,0}$ leads to conservation laws \cite{[24]}.

\textsuperscript{12}notice that the substitution $j \to -1-j$ is required when comparing with references \cite{[35]}.
the generic value of $m_2$ but still keeping the lowest-weight condition for the third operator, i.e., $m_3 + j_3 = 0$. In fact, the complete expression for the three-point function $A^{j_1,j_2,j_3}_{m_1,m_2,-j_3} = \langle \Phi^{j_1,j_2,j_3}_{j_1,j_2,j_3}(0) \tilde{\Phi}^{j_2,m_2,j_2}_{j_2,m_2,j_2}(1) \tilde{\Phi}^{j_3,-j_3,-j_3}_{j_3,-j_3,\infty}(\infty) \rangle$ in such case turns out to be

$$A^{j_1,j_2,j_3}_{m_1,m_2,-j_3} = (-1)^{m_2-m_2} \left( \frac{-\pi M \Gamma(\frac{1}{k})}{\Gamma(1-\frac{1}{k})} \right) \frac{\Gamma(j_1 - m_1 + 1)\Gamma(j_2 - m_2 + 1)}{\Gamma(-j_1 + m_1)\Gamma(-j_2 + m_2)} \times$$

$$\times \frac{G_k (-1 - \sum_{a=1}^3 j_a - \frac{k}{2}) G_k (-j_{12} - \frac{k}{2}) G_k (1 + j_{13} - \frac{k}{2}) G_k (-j_{23} - \frac{k}{2})}{G_k (-1) G_k (-2j_1 - 1) G_k (-2j_2 - k) G_k (2j_3 + 1)}$$

(31)

where $j_{ab} \equiv 2j_a + 2j_b - \sum_{c=1}^3 j_c$ and where the $G_k$ functions are given in terms of the double Barnes functions $\Gamma_2$ by the following expression

$$G_k(x) = (k - 2) \sum_{a=1}^3 j_a - \frac{k}{2} \Gamma_2(-x, 1, k - 2) \Gamma_2(k - 1 + x, 1, k - 2)$$

being

$$\log(\Gamma_2(x, 1, y)) = \lim_{\varepsilon \to 0} \frac{\partial}{\partial \varepsilon} \left( \sum_{n=0}^{\infty} \sum_{m=0}^{\infty} (x + n + my)^{-\varepsilon} - \sum_{n=0}^{\infty} \sum_{m=0}^{\infty} (1 - \delta_{n,0}\delta_{m,0})(n + my)^{-\varepsilon} \right)$$

The expression (31) is proportional to a factor $\delta(\omega_1 + \omega_2 + \omega_3 + 1)$ which stands from the integration over the free fields $X$ and $T$. This expression basically corresponds to the standard three-point function by replacing the quantum number as $j_2 \to -j_2 - \frac{k}{2}, j_3 \to -1 - j_3$. Moreover, since the affine properties of conjugate representations are defined up to a $m$-independent factor, then the considerations regarding the relative normalization between different representations also hold in this analysis. For instance, the formula (31) can receive an additional factor $\sim B(j_2)$ given by the normalization of the second vertex $\tilde{\Phi}^{j_2,m_2,j_2}_{j_2,m_2,j_2}$.

A fact which will turn out to be crucial in the last section is that the $m$-independent pole conditions of the formula (31) are located at

(32) \ $1 + j_1 + j_2 - j_3 - \frac{k}{2} \in \mathbb{Z}_{\geq 0} + \mathbb{Z}_{\geq 0}(k - 2), \quad -j_1 - j_2 + j_3 - \frac{k}{2} \in \mathbb{Z}_{\geq 0} + \mathbb{Z}_{\geq 0}(k - 2)$

(33) \ $1 - j_1 + j_2 + j_3 - \frac{k}{2} \in \mathbb{Z}_{\geq 0} + \mathbb{Z}_{\geq 0}(k - 2), \quad j_1 - j_2 - j_3 - \frac{k}{2} \in \mathbb{Z}_{\geq 0} + \mathbb{Z}_{\geq 0}(k - 2)$

(34) \ $1 + j_1 - j_2 + j_3 - \frac{k}{2} \in \mathbb{Z}_{\geq 0} + \mathbb{Z}_{\geq 0}(k - 2), \quad -j_1 + j_2 - j_3 - \frac{k}{2} \in \mathbb{Z}_{\geq 0} + \mathbb{Z}_{\geq 0}(k - 2)$

(35) \ $-1 - j_1 - j_2 - j_3 - \frac{k}{2} \in \mathbb{Z}_{\geq 0} + \mathbb{Z}_{\geq 0}(k - 2), \quad 2 + j_1 + j_2 + j_3 - \frac{k}{2} \in \mathbb{Z}_{\geq 0} + \mathbb{Z}_{\geq 0}(k - 2)$

Within the context of the $SL(2, \mathbb{R})_k/U(1) \times U(1)$ WZNW model, the divergences (32)-(35) can be understood in terms of the analysis presented in [9]: these come from the integration over the spacetime coordinate $\phi$; and the shifting in $-\frac{k}{2}$ precisely corresponds to the fact that the string states have no defined $\omega$ number and in the case of winding violating processes the worldsheet operator mainly contributing to the pole takes the form $\sim e^{\sqrt{-\omega}(j-\frac{1}{2})}\phi$ instead $\sim e^{\sqrt{-\omega}j}\phi$ (see [13] and [16], cf. [11]).

The formula (31) is (up to a minor generalization) the free field computation of correlators describing the scattering processes violating the winding number conservation in string theory.
in $AdS_3$ presented in [2]. However, we obtained here the factor (30) which, among other things, enables us to perform a comparison with (its dual) sine-Liouville field theory. We will show that, in particular, such $m$-dependent group theoretical factor is in good correspondence with the one arising in the dual model. Besides, we can also notice that similar factor was found in reference [9] for string scattering processes violating the winding number conservation in $AdS_3$ geometry, where the computation includes the coincidence limit of the spectral flow operator and one of the vertex involved in the interaction. By using (23), it is feasible to write the factor standing in the expression found in [9] as $(-1)^{m_3-m_2} \prod_{a=1}^{3} \frac{\Gamma(1+j_a-m_a)}{\Gamma(-j_a+m_a)}$.

As we just mentioned, as a consistency check of the formula for winding violating three-point function in WZNW theory, we can perform a comparison with the analogous result known for sine-Liouville dual theory. The residues for correlators of winding violating processes in sine-Liouville theory were computed in [4]. Indeed, a careful computation shows that the analytic structure of such observables in both CFT’s exactly agree. We give the details of the comparison in section 5.

4. Remarks

The free field description of non-compact two-dimensional conformal field theories turned out to be a useful tool to work out the features of this class of non-trivial models. In [2] [17] [35], among many other papers, the scope of this representation proved to be suitable to obtain the whole expression for the two and three-point functions in $SL(2, \mathbb{R})_k$ WZNW model. In this note, our intention was to revisit and extend its study.

Addendum to references [1] and [2]. We presented here a continuation of the study of references [1] [2] regarding the Dotsenko conjugate representations of $sl(2)_k$ vertex algebra. We pointed out the relevance of operators [13]–(20) in the context of free field representations; and we remark that these should be included in the bestiary in order to observe interesting features of the construction and consider the discussion complete. For example, we discussed the relation between the conservation laws yielding from the integration over the zero-mode of free fields and the Dotsenko prescription for the charge symmetry conditions (see [28]). We also discussed the $k \to 3$ limit of the screening operators, whose functional form (20) manifestly shows the connection with the $c = 1$ matter model, and we extended the Dotsenko-like highest-weight operators [1] [2] belonging to the conjugate representations of $SL(2, \mathbb{R})$.

We showed how to construct $\beta$-dependent conjugate representations of vertex operators describing winding states in $SL(2, \mathbb{R})_k/U(1) \times U(1)$ by extending the free field representation of the simplest discrete states on the two-dimensional black hole; obtaining, in this way, Kac-Moody primary states on the product $SL(2, \mathbb{R})_k/U(1) \times U(1)$ (see [13])

\footnote{for this purpose, it is necessary to rename the index of the third vertex as $4 \to 3$ and conciliate the nomenclatures by changing $j \to j + 1$. In order to perform a comparison with the formula presented in [9]. It could be also helpful to take into account that the following equation holds $G_k(-1 - j_1 - j_2 - j_3 - \frac{k}{2}) = (k - 2)^2 \Gamma(4j_1 + j_2 + j_3 + 1) \prod_{a=1}^{3} \frac{(1+j_a-m_a)}{\Gamma(-j_a+m_a)} G_k(-3 - j_1 - j_2 - j_3 + \frac{k}{2})$; this permits to show the exact agreement existing between the analytic properties of the formulas for three-point functions presented in [2] and [9].}

\footnote{Besides, other operators refered here, e.g. [27], were previously studied in the literature; for very interesting studies of world-sheet operators see [3] [5] [8] [9] [22] [22] [50].}
A word on supersymmetry. As we mentioned in the introduction, the conformal model formulated on the product $SL(2, \mathbb{R})/U(1) \times U(1)$ appears in different contexts, e.g. the proof on the non-ghost theorems on $AdS_3$ and the constructions of models with $N=2$ supersymmetries. For instance, in relation to this aspect, in [36] it was shown how to construct this class of supersymmetric models on the product $AdS_3 \times N$, being $N$ a compact manifold containing a $U(1)$ affine symmetry. The construction basically follows the steps of Kazama-Suzuki method; i.e. three free fermions $\psi^a$, $a \in \{+, -, 3\}$ are considered in order to realize the superconformal extension of the $sl(2)_k$ algebra, where the Kac-Moody level is shifted as usual. An additional free boson and a free fermion representing the $U(1)$ of $N$ have to be included as well. In reference [37] the authors explained in detail how to split the $U(1)$ component of the factor $N$ in order to bosonize the fermions realizing the $sl(2)_k$ algebra. The important point which makes contact with our discussion is the fact that the conjugate representations we were describing here can be systematically extended to the case with $N=2$ worldsheet supersymmetries in a straightforward way. For example, it is feasible to see that non-trivial zero-weight operators (perhaps describing conjugate representations of the identity operator) can be constructed by a (non-unique) linear combination associating the identities $\Phi^{\pm 1}_{j+k/2,\mp k/2}$ and the free fermions $\psi^\pm$, once the shifting $k \rightarrow k + 2$ is adequately taken into account. The winding violating processes were discussed in [38] within the context of the $N=2$ supersymmetric version of the theory in a rather different approach, which involves the twisting of the supercharges which have to be inserted in the correlators to change the picture of the operators. Here, we restricted our discussion to the bosonic theory. The supersymmetric theory is studied in the recent paper [10].

Conjugate representations in $SL(2, \mathbb{R})_k/U(1) \times U(1)$ WZNW theory. A deeper understanding of the connection between the discrete states in two-dimensional black hole geometry and the conjugate representations we presented here is, of course, desirable. Here, we have found interesting pointing out its existence, to suggest the mentioned connection and to remark the main properties.

Then, let us summarize what, in our opinion, are the principal properties of the conjugate representations $\tilde{\Phi}^\omega_{j,m,\bar{m}}$. We do this as follows:

The first important thing is that representation $\tilde{\Phi}^\omega_{j,m,\bar{m}}$ includes the Dotsenko conjugate representation [21] for the particular case $\tilde{\Phi}^{-1}_{j+1/2,-1,j+1/2}$. And it also generalizes the highest-weight states $\tilde{\Phi}^\beta_{j,j,j}$ considered in reference [24]. The $\beta$-dependent representation presented here also generalizes the functional forms recently proposed in [10] (see eq. (2.101) of this reference). On the other hand, this representation includes the free field representation of Bershadsky-Kutasov discrete states [14] on 2D black hole for the particular evaluation $\tilde{\Phi}^{-1}_{-j,m+\bar{m}}$ (see [52] and references therein). And, precisely because of this, we observe that both screening operators $\mathcal{L}_I$ and $(\mathcal{L}_I)^{k-2}$ can also be written as particular values, namely $\tilde{\Phi}^{-1}_{1-\frac{k}{2},\frac{k}{2}}$ and $\tilde{\Phi}^{-1}_{\frac{k}{2}-2,\frac{k}{2}}$ respectively.

The representation $\tilde{\Phi}^\omega_{j,m,\bar{m}}$ has the same conformal properties (under Kac-Moody and Virasoro algebras) of the representation $\Phi^\omega_{j,m,\bar{m}}$. In this sense, we achieved to find a free field realization which is equivalent to $\Phi^\omega_{j,m,\bar{m}}$ but presents a functional form which goes like $\sim e^{\sqrt{2(j-\frac{1}{2})\phi}}$. 

(instead \( \sim e^{\sqrt{\pi/2}j\phi} \)) in the large \( \phi \) limit. This permits us to understand, for example, the divergences of the three-point functions \([31]\) in terms of the integration over the target space coordinate \( \phi \).

In relation with this last point, we find that when representations \( \tilde{\Phi}^{\omega}_{j,m,\bar{m}} \) are used (instead the standard Wakimoto form \( \Phi^{\omega}_{j,m,\bar{m}} \)) to compute correlation functions, the conservation laws coming from the integration over the zero-mode leads to violate the winding number. It is also closely related to the fact that certain identities satisfied by the evaluations \( \hat{\Phi}^{\omega-1}_{j,j,j} \) and \( \hat{\Phi}^{\omega+1}_{j,-j,-j} \) and \( \Phi^{\omega-1}_{-\frac{j}{2},-j,\pm\frac{k}{2}j,\pm\frac{k}{2}j} \) realize the spectral flow symmetry of \( \hat{sl}(2)_k \) affine algebra.

The last properties enumerated above suggest an interpretation for representation \( \tilde{\Phi}^{\omega}_{j,m,\bar{m}} \) as the one describing the \( \omega = 1 \) contribution of the wave function of a string state in \( AdS_3 \), i.e. as it was pointed out in \([9]\), the states in \( AdS_3 \) have no defined \( \omega \) number and then, even for states with well defined energy, one should write the corresponding wave function as a linear combination of different contributions \([9]\). This manifests the fact that winding number is not a conserved quantity in this space. Schematically, this is represented by the series

\[
\Psi_{j,m,\bar{m}} = \Psi^{(\omega=0)}_{j,m,\bar{m}} + \Psi^{(\omega=1)}_{j,m,\bar{m}} + \ldots
\]

Consequently, we are claiming that the following realization holds for this

\[
\Psi_{j,m,\bar{m}} = \Phi^0_{j,m,\bar{m}} + \tilde{\Phi}^0_{j,m,\bar{m}} + \ldots
\]

where we are proposing this meaning for the conjugate representation \( \tilde{\Phi}^0_{j,m,\bar{m}} \) we have written down. Notice that it is not simply the sum of states with different \( \omega \) numbers.

In this context, we used the free field representation \( \tilde{\Phi}^{\omega}_{j,m,\bar{m}} \) to write the formula \([31]\) for correlators describing processes which violate the winding number conservation in \( SL(2,\mathbb{R})_k/U(1) \times U(1) \) WZNW model. And we obtained the \((m\text{-dependent})\) group theoretical factor \([30]\).

**Correlation functions and duality.** Once the construction of analogous correlation functions representing processes which violate the total winding number in sine-Liouville conformal field theory is analysed within the context of the prescription proposed in \([4]\)\(^{15}\), we are able to perform a comparison of the analytic structure of this class of (non-conservative) three-point correlators for both conformal models.

In previous works on these subjects, the discussion about the integration over the zero-mode of sine-Liouville fields turned out to be a relevant point when studying the analytic structure of two-point \([5]\)\([13]\) and three-point \([4]\) winding conserving processes. We observe here that the winding violating processes are not the exception, since the analysis of these observables leads us to obtain the correct overall factor standing in the correlators which precisely yields from the integration over the zero-mode in sine-Liouville CFT.

This consideration is an important step because if one naively compare the formula for the residue of sine-Liouville correlators presented in reference \([4]\) with the three-point functions computed in \([2][9]\) for WZNW theory (without taking into account the divergent factor yielding from the integration over the zero-modes) the pole structures of both models would not agree. Thus, we write the complete analytic structure for sine-Liouville three-point functions in the next section in order to compare the observables of these CTF's properly.

\(^{15}\)we describe it in section 5.
Then, we are able to show that the analytic structure of both theories are in good agreement; including the \((m\)-dependent) group theoretical factor, the location of the zeros, the phase and the order and positions of the poles (see section 5). This result extends the previous analysis of reference [4] since includes the winding violating processes in the framework of the comparison. On the other hand, this presents another result in favor of checking particular cases of the FZZ conjecture, which, as mentioned, states the duality between the sine-Liouville model and the string theory on the euclidean version of two-dimensional Witten black hole, \textit{i.e.} the cigar manifold. Similar results were attributed to the seminal unpublished work [5].

5. On Three-point function in sine-Liouville field theory

In a more general context, several points could be mentioned as motivations to study the problem of two dimensional string theory in a winding background. An important example of this kind of conformal models is the sine-Liouville string theory, which has been recently discussed as an example of non trivial CFT belonging to a more general family of possible backgrounds of two-dimensional string theory [39, 40]; it was also studied in relation with the description of strong vortex and tachyon perturbations [11].

The purpose of this section is to study the correlation functions violating winding number in sine-Liouville CFT. To me more precise, we will perform a comparison between these correlators and the analogous computation in WZNW we described in section 3.

In fact, if one assumes the duality existing between these CFT’s, then this comparison represents a non-trivial check of the formulas for the observables computed in both models. This is, certainly, the main goal of this section.

\textit{On Fateev-Zamolodchikov-Zamolodchikov conjecture.} One of the most interesting results which can be found among the recent subjects of research is, perhaps, the conjectured strong-weak coupling duality relating the sine-Liouville conformal field theory and the WZNW model formulated on \(SL(2, \mathbb{R})/U(1)\) group manifold. This celebrated result is known as the Fateev-Zamolodchikov-Zamolodchikov conjecture (FZZ) [5] and, in the last years, it was successfully used in the study of properties of degenerated operators in non-compact conformal theories [42], in the computation of correlation functions in string theory on euclidean AdS\(_3\) and in the study of quantum corrections of the entropy of two-dimensional black hole [43] (see also the recent papers [44] and [45]).

It is usually suggested that the FZZ conjecture could be derived as some class of perturbation or reduction of other known results related to mirror symmetry [46]; indeed, a supersymmetric version of the duality has been proved, which states the equivalence of the \(SL(2, \mathbb{R})/U(1)\) Kazama-Suzuki model and N=2 super Liouville theory [47]. With the purpose to learn about other interesting results related to N=2 Liouville theory we draw the attention to reference [48].

Here, we address our attention to the analysis of correlation functions in sine-Liouville CFT.

In this context, let us essay a comparison between the analytic properties of the winding violating three-point correlators in WZNW model with similar computations made in the sine-Liouville model. Our input will be the results presented in the previous subsection and in reference [4], which contain the formulas for three-point functions describing processes violating the winding number conservation in both CFT’s respectively.
Comparisons between correlators of both models were previously considered, but restricted to the winding conserving processes; we present here the case of winding violating interactions. Similar analysis was attributed to the unpublished paper [5].

**Sine-Liouville conformal field theory.** Within the context of the geometrical interpretation of Liouville model as a two-dimensional string theory, the sine-Liouville theory represents the condensation of vortices. The action of this theory is given by

\[ S_2 = \frac{1}{4\pi} \int d^2 z \left( \partial \phi \bar{\partial} \phi - \sqrt{\frac{2}{k-2}} R \phi + \partial X \bar{\partial} X + \lambda e^{-\sqrt{\frac{2}{k-2}} \phi} \cos \left( \sqrt{\frac{k}{2}} (X_L - X_R) \right) \right) \]

where \( X(z, \bar{z}) = X_R(z) + X_L(\bar{z}) \).

Fukuda and Hosomichi proposed in [4] a free field realization of the correlation functions in this theory by means of the insertion of two different screening operators [16] and by evaluating a generalized Dotsenko-Fateev type integrals. The three-point correlators representing processes violating winding number were explicitly computed by the authors; this was achieved by the insertion of a different amounts of both screening charges.

In the context of formal aspects, similar integral representations have been discussed, for instance, in the free field realization of string theory on euclidean AdS_3 and in the case of two-dimensional black hole background (see [17, 35] and references therein). However, it is important to mention that several differences can be noticed if a detailed comparison of these models is performed; the role played by the screening charges and the conjugate representations of the identity operator are examples of these distinctions.

The vertex operators creating primary states from the vacuum of the theory can be written in terms of the bosonic free fields \((\phi, X)\) as

\[ \Phi_{j,m,\bar{m}}(z, \bar{z}) = e^{i \sqrt{\frac{2}{k-2}} \phi(z, \bar{z}) + i \sqrt{\frac{2}{k}} (mX_L(z) + \bar{m}X_R(\bar{z}))} \]

The conformal dimensions of such operators are given by

\[ h_{j,m} = -\frac{j(j+1)}{k-2} + \frac{m^2}{k} \]

satisfying the Virasoro constraint \( h_{j,m} = \bar{h}_{j,\bar{m}} = 1 \) as a requirement of string theory. The quantum numbers parametrizing the spectrum of strings fall within the lattice in the following form

\[ p \equiv m + \bar{m} \in \mathbb{Z} , \quad k \omega \equiv m - \bar{m} \in k\mathbb{Z} \]

which can be derived from the level matching condition (cf. section 2). The quantum numbers \( m \) and \( \bar{m} \) are identified with the right momentum \( \sqrt{\frac{2}{k}} P_L \) and the left momentum \( \sqrt{\frac{2}{k}} P_R \) on the cylinder respectively. These can be compared with the case of 2D black hole \( SL(2, \mathbb{R})/U(1) \).

The central charge of sine-Liouville conformal model is given by

\[ c = 2 + \frac{6}{k-2} \]

Then, the restriction \( c = 26 \) is also required to define the string theory.

---

[16] The screening operators realize the interaction term of sine-Liouville action; see [11].

[17] Indeed, the nomenclature here is usual in the treatement of WZNW models; though, we use it here in this context for convenience with the intention to present the analysis results of reference [4] in a clear way.
The prescription for correlation functions. As a first step in our analysis, we consider necessary to start by briefly reviewing the integral construction proposed in [4]. The treatment of the sine-Liouville interaction term as a perturbation fits in the philosophy of the Coulomb gas realization. Actually, the introduction of interaction effects can be viewed as the insertion of screening charges into the correlation functions.

Let us define the screening operators by noticing that the interaction term can be rewritten in the following way

\[ \frac{\lambda}{4\pi} \int d^2z e^{-\sqrt{\frac{\lambda}{2}} \phi} \cos \left( \sqrt{\frac{k}{2}} (X_L - X_R) \right) = \frac{\lambda}{8\pi} \int d^2z \left( \Phi_{1 - \frac{k}{2}, \frac{k}{2}, -\frac{k}{2}, \frac{k}{2}} + \Phi_{1 - \frac{k}{2}, -\frac{k}{2}, \frac{k}{2}, \frac{k}{2}} \right) \]

Now, we move to the correlation functions. The Coulomb-gas like prescription for the correlators applied to the case of sine-Liouville theory leads to write down the following integral expression for the general N-point functions:

\[ A_{j_1 \cdots j_N} = \frac{\lambda^{s_+ + s_-}}{\Gamma(s_+ + 1)\Gamma(s_- + 1)} Vol(SL(2, \mathbb{C})) \prod_{a=1}^{N} \int d^2z_a \prod_{a < b}^{N-1,N} |z_a - z_b|^{\frac{4j_{ab}}{k}} \times \]

\[ \times (z_a - z_b)^{\frac{2}{k}m_a m_b} (\bar{z}_a - \bar{z}_b)^{\frac{2}{k}m_a m_b} \prod_{r=1}^{s_+} \int d^2u_r \prod_{l=1}^{s_-} \int d^2v_l \times \]

\[ \times \prod_{a=1}^{N} \left( \prod_{r=1}^{s_+} |z_a - u_r|^{2(j_a + m_a)} (\bar{z}_a - \bar{u}_r)^{p_a} \prod_{l=1}^{s_-} |z_a - v_l|^{2(j_a - m_a)} (\bar{z}_a - \bar{v}_l)^{p_a} \right) \times \]

\[ \times \left( \prod_{r < t}^{s_+ - 1, s_+} |u_r - u_t|^2 \prod_{l < t}^{s_- - 1, s_-} |v_l - v_t|^2 \prod_{l=1}^{s_-} \prod_{r=1}^{s_+} |v_l - u_r|^{2 - 2k} \right) \]

where \( d^2u_r = \frac{du_r \, d\bar{u}_r}{2\pi i} \) (resp. \( z_a, w_l \)). This is the standard representation for the perturbative analysis of conformal models. A factor of the form \( \sim \Gamma(-s_+) \Gamma(-s_-) \) could emerge in the functional integration for certain particular naïve prescription for the evaluation of the product of delta functions in the integration over the zero-mode of the \( \phi \) field; however, it is necessary to observe that this pair of gamma functions do not indicate the correct pole structure yielding from the integration. These gamma functions before the expression for residue would be divergent for \( s_\pm \in \mathbb{Z}_{\geq 0} \). The integration over the zero-modes encodes certain subtleties when two different screening operators are considered and, here, it receives importance in the context of our further discussion about the pole structure; we will consider the corresponding divergent pole contribution yielding in such integration opportunistically below.

The charge symmetry conditions, yielding from the integration over the zero-modes, take the form

\[ \sum_{a=1}^{N} j_a + 1 = \frac{k - 2}{2} (s_+ + s_-), \quad \sum_{a=1}^{N} m_a + \bar{m}_a = \frac{k}{2} (s_+ - s_- \pm s_+ \mp s_-). \]

On the other hand, let us mention that the existence of non-trivial zero-dimension fields in the world-sheet theory, namely

\[ \Phi_{\frac{k}{2}, \frac{k}{2}, \frac{k}{2}, -\frac{k}{2}} (z, \bar{z}) =: e^{-\sqrt{\frac{k}{2}} \phi(z, \bar{z}) \pm i \sqrt{\frac{k}{2}}(X_L(z) - X_R(\bar{z}))} : , \]
could suggest the idea to include such fields in correlators with the purpose to break the chiral balance of winding number without introducing a different amount of both screening charges; this idea was considered in references [5] and [9] within the context of WZNW model. In fact, it is possible to show that if this alternative construction is considered in sine-Liouville model, then differences appear with respect of realization [4] when the factorization limit is performed.

Here, our intention is to consider the structure of the correlation functions representing processes violating the total winding number for the case of sine-Liouville string theory as it was originally effectuated in reference [4]. Computations of analogous quantities were presented for the case of the $SL(2, \mathbb{R})_k$ WZNW model in references [2, 5, 9]. Despite the similarities between both CFT’s, substantial differences between them can be emphasized: an example of these is the role played by the screening operators of the sine-Liouville CFT and the WZNW model; i.e. in the case of sine-Liouville theory the violation of the winding number is produced by the presence of the sine-Liouville interaction term (which is manifestly represented in the free field realization by the insertion of a different amounts of each screening operators $s_+$ and $s_-$), meanwhile, the understanding of the violation of the total winding number in the case of the WZNW model involves a more subtle approach because of the non-explicit symmetry breaking at the level of the classical action. Moreover, in terms of the string theory on the cigar and string theory on $AdS_3$ the violation ($\delta \omega \neq 0$) is related to the topological properties of these simply connected manifolds.

The comparison between the pole structure of the expression for winding violating processes in sine-Liouville theory [4] and the similar expression for the non-compact WZNW model becomes a subject of great importance within the context of the study of FZZZ conjecture. The agreement between both computations found here could be other of the convincing confirmations of the validity of the hypothesis of this strong-weak duality. We focus the attention on this in the following paragraphs.

Now, let us briefly analyse the computation presented by Fukuda and Hosomichi in the cited paper. There, the authors have been able to write down a generic three-point function on the sphere by explicitly evaluating a modified Dotsenko-Fateev type integral formula. Among other results, they proved that the winding number conservation can be violated up to $\pm 1$ (i.e. $|\delta \omega| \leq 1$). This is in agreement with previous calculations effectuated by Zamolodchikov et al.

In a very careful analysis of the integral representation, the authors of reference [4] have shown that it is feasible to translate the integrals $\prod_{r,l} \int d^2 u_r \int d^2 v_l$ over the whole complex plane into the product of contour integrals. Thus, the integral representation turns out to be described by the techniques developed in the context of the known integral realization of this class of conformal field theories. In [4] these techniques were used and extended in order to define a precise prescription to explicitly evaluate the correlators by giving the formula for the contour integrals in the particular case of sine-Liouville theory. The first step in the calculation was to decompose the $u_r$ complex variables (resp. $v_l$) into two independent real parameters $(\Re (u_r), \Im (u_r))$ which take values in the whole real line. Secondly, a Wick rotation for $\Im (u_r)$ was performed in order to introduce a shifting parameter $\varepsilon$ which is then used to elude the poles in $z_a$. Then, the contours are taken in such a way that the inserting points $z_a$ are avoided by considering the alternative order with respect to these inserting points. A detailed description for the particular prescription could be found in the original reference, where the authors refer to the quoted works by Dotsenko et al. [22, 21, 49, 50].
The main results of [4] were the explicit formulas for three-point correlation functions in sine-Liouville CFT, including the cases of winding violating processes as well.

Also in [4], the obtained expression for correlators in sine-Liouville theory was compared with the known formula for the three-point function in the WZNW model on the coset $SL(2, \mathbb{R})/U(1)$ for the particular case where the total winding number is conserved. The authors showed that the two expressions are in good agreement in that case. Here, we are interested in extending the comparison to the winding violating correlators.

On the other hand, the comparison of the functional form of 2-point functions in both models can be studied with detail in the second section of reference [43]. That analysis follows the steps developed in the original work by Zamolodchikov et al. There, it is shown how the integration over the zero-modes of sine-Liouville fields leads to obtain the same analytic structure of the 2-point function in WZNW model on the cigar manifold.

**The three-point function violating the winding number.** Again, with the intention to extend this comparison, let us constrain here the expressions for three-point functions for both theories in the case where the winding number is violated, being $|\delta \omega| = 1$.

First of all, for our purpose, we consider the formula for the evaluation of the residues of the (non-perturbative) three-point functions in sine-Liouville theory [4]. This is given in terms of $\Upsilon_b$ functions as follows

\[
\mathcal{A}_{m_1,m_2,m_3}^{j_1,j_2,j_3} = \frac{b^2(1+\sum_{a=1}^3 j_a -1)(b^{-2}+2) (-1)^b(1+\sum_{a=1}^3 j_a + \frac{1}{2k})^{m_3 + m_3}}{\Gamma^2 \left( b^2 \left( 1 + \sum_{a=1}^3 j_a + \frac{1}{2k} \right) \right) \Upsilon_b \left( b \left( 1 + \sum_{a=1}^3 j_a + \frac{1}{2k} \right) \right)} \times \prod_{a=1}^3 \frac{\Gamma(j_a + m_a + 1) \Upsilon_b \left( b \left( 2j_a + 1 \right) \right)}{\Gamma(m_a - j_a) \Upsilon_b \left( b \left( 2j_a - \sum_{c=1}^3 j_c + \frac{1}{2k} \right) \right)}
\]

(44)

where $b^{-2} = (k - 2)$ and the $\Upsilon_b$ functions are defined by

\[
\log \Upsilon_b(x) = \frac{1}{4} \int_0^\infty \frac{d\tau}{\tau} \left( b + b^{-1} - 2x \right)^2 e^{-\tau} - \int_0^\infty \frac{d\tau}{\tau} \frac{\sinh^2 \left( \frac{\tau (b + b^{-1} - 2x)}{2} \right)}{\sinh \left( \frac{\tau}{2} \right) \sinh \left( \frac{\tau}{2} \right)}
\]

These functions have zeros in the lattice

\[
x \in -b\mathbb{Z}_{\geq 0} - b^{-1}\mathbb{Z}_{\geq 0}, \quad x \in b\mathbb{Z}_{\geq 0} + b^{-1}\mathbb{Z}_{>0}
\]

And these\(^1\) can be written in terms of the special functions $G_k$ taking into account the equivalence

\[
\Upsilon_b^{-1}(-bx) = b^{b^2x^2 + (1+b^2)x} G_{b^{-2}+2}(x)
\]

(46)

Now, let us observe that the formula [14] for the residue, obtained originally in [4], has to be complemented by including the divergent overall factor $\left( \sum_{a=1}^3 j_a + 1 - \frac{k-2}{2}(s_+ + s_-) \right)^{-1}$ coming from the integration over the zero-mode of sine-Liouville fields. In fact, the insertion of screening charges in conformal theories with non-compact target space leads to obtain a divergent factor (e.g. the factors of the form $\sim \Gamma(-s)$ in Liouville CFT); in sine-Liouville theory this factor

\(^1\)For a detailed discussion about the analytic properties of $\Upsilon_b$ functions in a related context see [51].
yields from the integration over the zero-modes of the fields $\phi$ and $X$. Near these poles, the correlation functions take the schematic form\(^{19}\)

$$
\mathcal{A}_{1,\ldots,N}^{j_1,\ldots,j_N} = \frac{\lambda^{s_+ + s_-} \left( \prod_{a=1}^{N} \int d^2 z_a \Phi_{j_a,m_a,\bar{m}_a}(z_a, \bar{z}_a) \left( \int d^2 u \Phi_{1,-k/2,-k/2}(u, \bar{u}) \right)^{s_+} \left( \int d^2 v \Phi_{1,-k/2,-k/2}(v, \bar{v}) \right)^{s_-} \right)}{\Gamma(s_+ + 1) \Gamma(s_- + 1) \left( \sum_{a=1}^{N} j_a + 1 - \frac{k-2}{2} (s_+ + s_-) \right)}
$$

This implies that the formula should include an additional factor $\sum_{a=1}^{3} j_a + 1 - \frac{k-2}{2} (s_+ + s_-)$ in the denominator (cf. \(\text{43}\)). This overall factor has a crucial role in the pole structure as we will see. For instance, it is easy to observe that, in the particular case $s_- = 0$, it leads to the expected overall factor $\Gamma(-s_+)$ and the delta function $\delta \left( \sum_{a=1}^{N} j_a + 1 - \frac{k-2}{2} s_+ \right)$.

On the other hand, we find convenient to remark that \(\text{46}\) and the functional properties of $G_k$ functions imply

$$
\Upsilon_b \left( b \left( \sum_{a=1}^{3} j_a + \frac{k}{2} \right) \right) = \frac{b^2 \Gamma(\sum_{a=1}^{3} j_a + 1 - \frac{k}{2})}{\Gamma(b(\sum_{a=1}^{3} j_a + \frac{k}{2}))} \Upsilon_b \left( b \left( \sum_{a=1}^{3} j_a + \frac{k}{2} \right) \right)
$$

And we also observe that the expansion $\Gamma(e - n) \sim \frac{(-1)^n}{e^{(1+n)}} + O(1) + O(e)$ leads to

$$
\frac{(-1)^b \Gamma(\sum_{a=1}^{3} j_a + 1 - \frac{k}{2})}{(\sum_{a=1}^{3} j_a + 1 - \frac{k}{2} (s_+ + s_-)) \Gamma(\frac{1}{2} + b(\sum_{a=1}^{3} j_a + 1))} \sim \frac{b^2 \Gamma(1 - b(\sum_{a=1}^{3} j_a + \frac{k}{2}))}{\Gamma(b(\sum_{a=1}^{3} j_a + \frac{k}{2}))}
$$

where we have identified in the limit $b^{-2} \epsilon = \sum_{a=1}^{3} j_a + 1 - \frac{k-2}{2} (s_+ + s_-)$ (see equation \(\text{42}\)). The last two relations, considered together, permit us to observe that the whole $m$-independent pole structure of the formula \(\text{44}\) is codified in four $\Upsilon_b$ functions standing in the denominator, which now lead to the following formula

$$
\mathcal{A}_{m_1,m_2,m_3}^{j_1,j_2,j_3} = \frac{b^2 \sum_{a=1}^{3} j_a (b^2 + 1) + 2(-1)^{m_a+\bar{m}_a} b^2 (1 + \sum_{a=1}^{3} j_a)}{\Upsilon_b \left( b \left( 2 + \sum_{a=1}^{3} j_a + \frac{1}{2b^2} \right) \right)} \prod_{a=1}^{3} \frac{\Gamma(j_a + m_a + 1) \Upsilon_b \left( b \left( 2j_a + \sum_{c=1}^{3} j_c + \frac{1}{2b^2} \right) \right)}{\Gamma(m_a - j_a) \Upsilon_b \left( b \left( 2j_a - \sum_{c=1}^{3} j_c + \frac{1}{2b^2} \right) \right)}
$$

Then, the three-point function in sine-Liouville theory in the case $|\delta\omega| = 1$ presents poles given by the zeros of these $\Upsilon_b$ functions; those singular points are precisely located at \(\text{32}-\text{35}\). Notice that the Weyl reflection is (including the factor we pointed out) closed among this set of pole conditions (cf. \(\text{43}\)).

\textit{Comparing with the WZNW theory.} Now, in analogous way, we can return to the analysis of the pole structure of the three-point function for winding violating processes in the case of the $SL(2, \mathbb{R})_k/U(1) \times U(1)$ WZNW model. We already studied the three-point function for WZNW model in the previous section; and this is given by \(\text{31}\). Then, the positions of the poles are determined by the analytic structure of the $G_k$ functions, which present poles at \(\text{32}-\text{35}\). And actually, we find an exact agreement between the pole structures of both \(\text{17}\) and \(\text{31}\) since the pole conditions \(\text{32}-\text{35}\) match exactly with the singular points \(\text{15}\) evaluated for the expression \(\text{31}\).

The crucial point here was the overall factor $\epsilon^{-1}$. Its inclusion in the formula for sine-Liouville three-point function is necessary to conclude the agreement between both CFT’s.

\(^{19}\)G.G. is grateful to K. Hosomichi for drawing his attention to this point.
since, otherwise, a discrepancy between the pole structure of both WZNW and sine-Liouville
CFT's would appear due to an additional pole. This is because if one naively compares the
formula for the residue of reference [4] and the correlators computed in [2, 9], without the
consideration of the divergent factor yielding from the integration over the zero-modes of sine-
Liouville fields we remarked here, the pole conditions for sine-Liouville which correspond to
\((35)\) should be replaced by
\[
-j_1 - j_2 - j_3 - \frac{k}{2} \in \mathbb{Z}_{\geq 0} + \mathbb{Z}_{\geq 0} (k - 2), \quad 1 + j_1 + j_2 + j_3 - \frac{k}{2} \in \mathbb{Z}_{\geq 0} + \mathbb{Z}_{\geq 0} (k - 2)
\]
which does not coincide with the analogous lattice coming from the formula for WZNW and,
on the other hand, breaks the Weyl reflection symmetry of the set of pole conditions. This can
be seen directly by the \(\Upsilon_b\) appearing in equations (47) and (44).

For instance, the poles at \(\sum_{a=1}^3 j_a = \frac{k}{2} - 2\) arises in sine-Liouville theory because of the
global factor \(\sim \Gamma(-s_+);\) and this factor comes from the integration over the zero-mode. These
poles would be at \(j_1 + j_2 + j_3 + 1 \in \mathbb{Z}_{\geq 0} (\frac{k}{2} - 1),\) and these are well understood in terms of the
integration over the target space because of its non-compactness.

Besides, we see how the group theoretical factor \((30)\) standing in WZNW conformal theory
is also in agreement with its conjectured dual model. Strictly speaking, the transformation
\(\hat{m} + m \rightarrow \hat{m} - m\) needs to be considered when comparing with the theory on \(SL(2, \mathbb{R})/U(1)\).
This identification is precisely consistent with the definition of \(\omega\) winding number \(\omega\) and angular
momentum \(p\) in both theories.

Let us observe that also the zeros of both expressions \((31)\) and \((47)\) agree due to Weyl
reflection considered for \(j_2\) and \(j_3,\) and the agreement is exact despite the distinctive argument
\(-2j_2 - k\) of the \(G_k\) function in \((31).\) Hence, we conclude that both CFT’s are in good agreement
when the comparison embraces the \(\omega\) winding violating three-point correlation functions as well.

The goal of these paragraphs was to address the attention to this agreement since this
particular point is an important step in the checking of the conjectured duality. On the other
hand, by inverting the reasoning, the comparison of both pole structures can be used as a
mechanism for testing the results proposed in the literature as representing correlators in these
theories once the FZZ conjecture is assumed. Actually, with this original motivation we pointed
out here the main features of the comparison. And, indeed, this comparison allowed us for
arguing that the additional pole yielding from the integration over the zero-modes of sine-
Liouville fields leads to the correct pole structure in the three-point correlators which violate
\(\omega\) winding number.

G.G. is very grateful to J.M. Maldacena and K. Hosomichi for very useful discussions. He
also thanks Simeon Hellerman for conversations and for his interest on this work. D.L. thanks
C. Núñez for many conversations. G.G. was supported by the Institute for Advanced Study
IAS and Fundación Antorchas. D.L. was supported by the Ministerio de Educación y Ciencias
(Spain) through FPU grants.
REMARKS ON FREE FIELD REALIZATION OF $SL(2,R)_{k}/SU(1) \times U(1)$ WZNW MODEL
