Introduction: Persons with severe and persistent mental illness (SPMI) have multiple and complex needs, many of which are not health related. Mental health services are unable to address these needs without collaboration with other agencies. In the absence of this collaboration, persons with SPMI often fall through the system cracks and are unlikely to experience recovery. Furthermore, previous studies have shown that unmet accommodation needs are associated with unmet needs in other areas. This study aimed to ascertain whether a care coordination model adopted in Australia’s Partners in Recovery [PIR] initiative was able to reduce unmet needs in such persons and also if meeting accommodation needs were associated with meeting other needs.

Methods: This was a longitudinal study where met and unmet needs of clients measured using the Camberwell Assessment of Needs Short Appraisal Schedule (CANSAS) were compared at enrolment and exit from the PIR initiative. Logistic regression was used to examine the association between change in accommodation needs and change in other CANSAS variables.

Results: In total, 337 clients (66% of 508 clients) had both baseline and follow-up data and were seen within the time frame of 14 to 101 weeks. At baseline, the most frequently reported unmet needs were psychological distress, daytime activity, and company (89%, 72%, and 67%, respectively). At follow-up, these had decreased to 27%, 22%, and 22%, respectively. The proportions of clients with an unmet need at baseline who subsequently progressed to having that need met at follow-up ranged between 62% and over 90%. Change in accommodation needs from unmet to met was associated with changes in monetary needs and needs related to childcare, food, safety to self, education, and access to other services, with the greatest change seen for monetary needs (adjusted OR 2.87, 95% CI 1.76, 4.69).

Conclusions: Reducing needs of persons with SPMI is the starting point of recovery and is a good indicator of psychiatric care. Care coordination is a useful way to address multiple and complex needs of persons with SPMI. While addressing needs, priority must be given to meeting accommodation needs.

Keywords: needs assessment, psychiatric rehabilitation, severe mental disorders, care coordination, accommodation, housing, community mental health services, mental health services
INTRODUCTION

Persons with severe and persistent mental illness (SPMI) have multiple and complex needs, which are generally beyond the scope of traditional mental health services (1). Assessment of need is a good general measure of the number and severity of a client's problems in everyday life (2) and is critical in mental health rehabilitation (3). Hence, a change in needs from unmet to met gives an indication of the effectiveness of psychiatric care (4). People with a number of unmet needs are likely to experience a poor quality of life (5), and the longer these needs remain unmet, the less are the chances of recovery. However, when these needs are met, recovery becomes easier (6). There is hence a need for a reorganization of care delivery for people with multiple needs that focuses on recovery by addressing client needs and better care coordination (7). Any mental health service that aims to improve the quality of life of their clients, needs to actively assess and address their reported needs (6). The recognition of factors associated with each unmet need can help optimize planning and implementation of care (8).

The most common unmet needs reported by persons with SPMI are psychological distress, help with psychosomatic symptoms, daily activities, employment and volunteering, physical health problems, and money relating to money (1, 9, 10). A recent report has suggested that when accommodation needs are unmet, several other needs remain unmet (9). This observation is in accordance with previous research. For instance, people who have a mental illness and are homeless are less likely to receive public benefits and are more likely to experience severe poverty (11–13). Poverty is also the underlying cause of homelessness (14).

Homeless people with mental health problems are known to experience food insecurity (15, 16) because homelessness prevents the preparation and storage of food as well as precludes market and nonmarket activities needed for the preparation of food (17). Homeless persons also spend less on food and eat fewer meals than their housed counterparts (18). Homeless people do not have the means to afford transport even for basic needs, such as obtaining food or accessing health services (19). Homeless families also have difficulty caring for their children. They are forced to make big sacrifices for them, protecting them from harm and struggling with the restrictions of not having a home (20).

Medical problems are particularly prevalent among homeless people. Seizures, chronic obstructive pulmonary disease, (21), and oral and dental diseases are common (22). Continuous exposure to the elements predisposes homeless persons to respiratory infections and skin disease. Prolonged exposure to moisture, inadequate footwear, and walking long distances results in foot disorders, such as onychomycosis, tinea pedis, corns, and callouses (23, 24). Moreover, chronic conditions, such as hypertension, diabetes, and anemia are often either not treated or remain undiagnosed (25, 26). Violence is a constant threat to homeless people with high incidences of assault, murder, and rape. Physical injuries caused by falls and being struck by motor vehicles are also common among people who are homeless (25). Homeless people with a mental illness are unable to readily access health care services, which tend to exclude them as a result of stigma, prejudice, and the inadequacy of care available for their complex needs (27, 28).

A recovery-oriented service system that aims to address unmet needs of persons with SPMI requires collaboration between mental health services and other agencies, such as housing, welfare, general practices, and alcohol and drug services. This can be done either by service system integration (29) or by integration at the service delivery level (30, 31). Whereas integrating service systems is plagued with several barriers, such as inability to share information and reluctance of staff to take on more caseloads (29), integration at the service delivery level appears to be more feasible (32).

Care coordination is an example of integration at the service delivery level and has been identified as a core requirement for provision of such care (33, 34). Care coordination involves working with persons with SPMI to first identify and prioritize their needs, then liaising with multiple service providers to develop a care plan, and finally facilitating the provision of services according to that plan to meet clients' needs (32, 35). Care coordination was originally introduced to mental health services in the United States several decades ago (33), and the role came to be undertaken by the case manager. However, because of an increased workload, case managers in Australia now mostly focus on medication compliance, early warning signs, and crisis management, with little time for recovery-oriented work (35).

The Partners in Recovery (PIR) initiative of the Australian Government was set up to facilitate better coordination between clinical and other supports, to strengthen partnerships, to improve referral pathways, and to promote a community-based recovery model for persons with SPMI (36). It aimed to cover 24,000 people through 48 agencies across the country (36). The initiative was originally implemented from 2012 to 2016 and then extended until mid-2019 to enable transition to the National Disability Insurance Scheme (37).

The PIR model involved a regional lead organization that guided and supported implementing organizations. Each implementing organization had a team of care coordinators who worked with clients to develop a care plan based on their needs. Once a care plan was developed, the care coordinator (referred to as a support facilitator in the PIR program) brokered services from relevant agencies in accordance with the plan. Hence, the PIR initiative primarily aimed to reduce unmet needs of clients. Met and unmet needs were documented and monitored regularly during client-care coordinator meetings. Clients exited the program when they chose to or once most of their needs were met. The PIR initiative is described in Figure 1.

Conceptual Framework

To improve one’s quality of life, fulfillment of one’s needs is essential (38).

The conceptual framework developed for this study draws from aligning needs listed by the Camberwell Assessment of Need Short Appraisal Schedule (CANSAS) with Maslow's hierarchy of needs (39, 40) (see Figure 2). When needs listed by the CANSAS are classified according to Maslow's five-stage hierarchy, accommodation and food needs are basic physiological needs, and people tend to achieve physiological needs before other.
higher-level needs (38, 41). In the context of persons with SPMI, we postulate that addressing basic needs is necessary to be able to address higher-level needs. If accommodation (housing) needs are met, people will be better placed to receive social benefits, access better quality food, look after and protect their children, stay safe, and more readily access services.

Hence, we proposed two hypotheses:
1. That enrolling in the PIR initiative would reduce the number of clients' unmet needs; and
2. That meeting accommodation needs would be associated with meeting other higher-level needs.
METHODS

Study Design
This was a longitudinal study where met and unmet needs of clients were compared at enrollment and exit from the Gippsland PIR initiative.

Setting
This study was conducted in Gippsland—a non-metropolitan area in the state of Victoria with a population of over 270,000 people and covering an area of 41,600 km² (42). The PIR initiative in Gippsland is overseen by a not-for-profit regional health planning commissioning organization called Gippsland Primary Health Network (PHN) that formed a regional consortium with three Community Mental Health Support Services (CMHSS) and the Area Mental Health Service (AMHS) to implement and govern this initiative. CMHSSs are not-for-profit organizations specialized in recovery-focused nonclinical mental health service delivery. The AMHS adult services include an acute psychiatry inpatient service and a secure extended care unit located at the regional referral hospital, a residential rehabilitation care unit, a prevention and recovery care service, and community mental health teams dispersed across the region. The Gippsland PIR Consortium was later joined by a local Aboriginal Community Controlled Health Organization and the provider of intake services to the Gippsland PIR initiative.

Data Source
Data on clients who enrolled for the PIR initiative in Gippsland are stored by Gippsland PHN on an online purpose-built client information management system called Fixus (43). The Fixus database contains demographic data and scores from CANSAS. The CANSAS is the most commonly used instrument for needs assessment in mental health services (44–46). For the PIR initiative, three additional social and health domains, namely, employment and volunteering, cultural and spiritual, and other services, were added to the original 22 domains (47). Support facilitators verbally obtained and documented client responses on the Fixus database. Deidentified Fixus data were obtained in February 2019. Ethics approval for the study was obtained from Monash University Human Research Ethics Committee (Project ID: 17216; 18/12/2018–18/12/2023).

Data Analysis
Data were analyzed using Stata 15 (48). Demographic and health status data are reported as proportions or mean and standard deviation. For each area examined using the CANSAS instrument, “no problems (no needs)” and “some problems (needs met)” were coded as “needs met” versus “serious problems” or “unmet needs” (coded as “unmet needs”) and are reported as the proportions of participants with unmet needs at baseline who progressed to having those needs met at follow-up.

Logistic regression was used to examine the association between change in accommodation needs as the independent variable and change in other CANSAS variables as the dependent variables. In this analysis, “change” was defined as moving from having an unmet need at baseline to having a met need at follow-up. Odds ratios (ORs) and 95% confidence intervals (CIs) described the likelihood of changing from an unmet need to a met need in one area if accommodation needs also changed. The model was adjusted for age, sex, and time between baseline and follow-up (“weeks”). These confounders were included because they were intermittently associated with either unmet accommodation needs or other unmet needs using logistic regression. The variable “weeks” was not normally distributed and was transformed for analysis purposes. There was also a wide variation in this variable, with a range of 1 to 166 weeks. The 10th and 90th percentiles were used as cutoff points, excluding 98 clients from analysis. A further 73 clients were excluded because of having no follow-up data.

RESULTS

In total, 337 clients (66% of 508 clients) had both baseline and follow-up data and were seen within the time frame of 14 to 101 weeks. Differences in demographic and health characteristics between those included in analysis and those excluded because of time frames or incomplete follow-up were statistically significant for mean age only (included mean age 45.7 years, SD 11.3, excluded mean age 42.2 years, SD 11.1, p < 0.001). No other statistically significant differences between the included and excluded groups were seen.

Of the 337 included clients at baseline (Table 1), 56.1% were female, 49.3% lived alone, 48.8% had never married, 57.1% were not in the labor force, and 58.5% had senior secondary education or above. The mean number of weeks between baseline and follow-up was 50.8 weeks (SD 23.6). Most clients lived in a private residence (82.2%), and 46.0% had an accommodation tenure of <1 year (Table 2). As shown in Table 3, the most frequent principal diagnosis was mood (affective) disorders, whereas general practitioners were the most common service provider (54.3%).

The proportion of unmet needs for each variable measured in the CANSAS is shown in Figure 3. At baseline, the most frequently reported unmet needs were psychological distress, daytime activity, and company (89%, 72%, and 67%, respectively). At follow-up, these had decreased to 27%, 22%, and 22%, respectively. The least frequently reported unmet needs were basic education, telephone, and safety to others (15%, 12%, and 2%, respectively). At follow-up, these had decreased to 4%, 2%, and 2%, respectively).

The proportions of clients with an unmet need at baseline who subsequently progressed to having that need met at follow-up ranged between 62% and over 90% (Figure 4). The highest proportion of clients showing a change was seen for the variables safety to others (94.1%) and cultural or spiritual needs (93.9%). The lowest proportion was seen for alcohol abuse and childcare needs (62.3% and 66.3%, respectively). Table 4 shows associations between change in accommodation needs and change in other CANSAS variables between baseline and

| Time between baseline and follow up (weeks) | | 
| Mean (standard deviation)      | 50.8 (23.6) |  |
| Minimum–maximum                | 14–101 |         |

follow-up. The greatest change was seen for monetary needs (adjusted OR 2.87, 95% CI 1.76, 4.69), whereby the likelihood of changing from unmet to met monetary need was almost three times greater when accommodation needs also changed from unmet to met. Significant associations were also seen between changes in accommodation needs and changes in needs related to childcare, food, safety to self, education, and access to other services.

To test whether associations were similar according to length of time in PIR, we categorized weeks in PIR into three groups. Similar patterns of association were seen for all three categories but were more likely to be significant in categories of longer periods of time.

DISCUSSION

This study describes a care coordination model that was associated with a reduction in unmet needs of persons with SPMI. As discussed earlier, reducing client reported needs is the starting point of recovery (6, 49) and is a good indicator
FIGURE 3 | Unmet needs at baseline and follow-up in n=337 clients with severe and persistent mental illness.

FIGURE 4 | Proportion of clients with an initial unmet need who reported a met need or no problem at final follow-up.
of psychiatric care (4). Although some needs such as finding a partner can be difficult to assess properly, others might be more difficult to meet, such as needs related to substance abuse. Nonetheless, meeting clients' needs must be the starting point for mental health care (5). Our findings indicate that the PIR model was able to substantially reduce client needs.

Qualitative studies on the PIR initiative undertaken previously have shown that the model of care benefited not only clients and carers but also health professionals. Clients stated that they felt valued, got a better understanding of their illness, felt empowered to better engage with services, and were encouraged to make decisions about their lives (50, 51). Health professionals stated that the model of care promoted a team approach to client care and prevented duplication of services (50). It allowed them to better understand the roles of other professionals, improve relationships between organizations, and facilitate interagency collaboration (32). The model is also shown to be cost-effective (52). The PIR model can therefore be considered a useful recovery-oriented model of care for persons with SPMI.

This is perhaps the first study that shows that higher-level safety and esteem needs tend to get met when accommodation needs, which is a basic physiological need, get met. Previous evidence appears to be mixed. Whereas some have indicated that a person's higher-level needs usually come into play after basic needs are met (53), others argue that the hierarchy was more complicated (54). Nonetheless, MacPherson and colleagues suggest that services can more effectively address peoples' needs when they have housing (55), although it was not clear what specific factors could have contributed to those findings.

The present study found that meeting accommodation needs significantly increased the likelihood of meeting needs related to money, childcare, food, safety to self, education, and access to services. It is likely that people who were homeless did not attend their compulsory social service appointments regularly and hence did not receive their fortnightly payments. Once clients had stable accommodation, they were usually taught how to manage money and were supported to budget their income for food and payment of rent. Having a secure home also enabled parents (particularly single mothers) to better look after their children.

When accommodation needs were met, clients were able to learn about day-to-day living skills, such as buying better food from the supermarket. People in a stable home could also be linked into voluntary organizations that provided food to the home. In addition, when clients lived close to a food distribution point, they could access it without assistance. Once accommodation needs were met, clients did not have to worry about their next meal or where they would sleep. It was therefore easier to assist them in developing an action plan that focused on what they needed to do next. This empowered them to think about issues, such as education and employment. Other authors have also reported that permanent housing did enable clients to consider subsequent goals to improve one's life (54). When accommodation was located close to services that supported education, access was made easier. There are suggestions that meeting accommodation needs tends to show improvements in

---

mental health problems as well, although the evidence is still not robust (56).

It is widely accepted that social determinants, such as housing and employment, have a significant bearing on the mental health of individuals, and providing social and other nonclinical services is essential for their well-being (57). Although in Australia, the National Disability Insurance Scheme (NDIS) has been given the resources to assist persons with SPMI, funding allocations are far below estimated requirements (57). Even so, there is optimism for the future because Australia is in the process of identifying areas for mental health reform through the Productivity Commission’s inquiry into mental health (58). Commissioned in November 2018, this 18-month inquiry will examine how sectors, such as education, employment, social services, housing, and justice, can contribute to improving mental health and economic participation of persons with mental illness (58).

The reasons for the relatively high dropout rate in this study are unclear. Previous reports suggest that associations with disengagements with mental health services are complex and encompass sociodemographic and clinical variables, as well as variables related to service provision (59). The PIR model is quite new and different from traditional mental health care models. Anecdotally, service providers presume that dropouts could have been caused by the exacerbation of symptoms or transfer to another program. Symptoms in SPMI are known to wax and wane. When symptoms become worse, many people (particularly young people) tend to temporarily disengage from services and return when they feel better. As a result, there can be several cases of dropouts and re-enrollments. The PIR initiative was a new and innovative program in Australia. When individuals who were used to a system that did not necessarily take care of their needs became involved with it, they are likely to have been empowered to make it work for them, thereby transferring to the program that was closer to family and other supports. As a result, dropouts in this initiative could also have included a new enrollment in a neighboring program.

There are a few limitations in this study. No data on recovery were available, although another group has reported improved recovery in participants enrolled in the PIR initiative (60). There was also no control group, and although its focus was to address unmet needs, it is difficult to attribute change in needs entirely to the initiative.

CONCLUSION

There was a significant reduction in unmet needs reported by clients who enrolled in the care coordination model of the PIR initiative. The highest reductions in needs were for safety to others, cultural or spiritual, information on condition, benefits, and self-care. The least reductions in unmet needs were reported for psychological distress, company, drug abuse, childcare, and alcohol abuse. Meeting accommodation needs was associated with meeting needs related to money, childcare, food, safety to self, education, and access to other services. Care coordination is a useful way to address multiple and complex needs of persons with SPMI. While addressing needs, priority must be given to meeting accommodation needs.

DATA AVAILABILITY

The data sets for this manuscript are not publicly available because of copyright issues. Requests to access the data sets should be directed to Gippsland PHN (info@gphn.org.au).

AUTHOR CONTRIBUTIONS

AI conceived the idea for the study and wrote the initial drafts. NK helped obtain the data for the study. AB undertook data analysis. KS and NK contributed to the development of the manuscript. All authors read and approved the final version of the manuscript.

FUNDING

This study was funded by the Gippsland Primary HealthNetwork.

ACKNOWLEDGMENTS

The authors wish to thank Fixus technologies for providing the data for this study as well as Beth Fogerty and Tanya Hayes for their helpful comments on the results.
