Laboratory Findings, Vaginal Cytology and Histopathology in Bitches with Cystic Endometrial Hyperplasia – Pyometra Complex

Martin Llzazani, Alketa Qoku, and Luljeta Dhaskali

ABSTRACT

Cystic Endometrial Hyperplasia -Pyometra complex, a common pathological condition of uterus in bitches, it is attributed hormonal and bacteriological causes. It is studied in 10 bitches of cross and pure bred and aged from 1-13 years. In this study, the average age of animals was 8.33±1 year. Hematological and biochemical lab findings were evaluated in bitches with or without vaginal discharge. Lab findings were leukocytosis, neutrophilia and normocytic, normocromic anemia. Biochemical results shown increased of ALT and ALKP and a moderate of BUN. An increased number of parabasal and intermediate cells were detected in vaginal cytology. Histopathologic diagnosis confirmed thickness of uteri wall, a lot of cystic glands of it and the pus presented in lumen of uterus and its horns.

The purposes of this study were that through different techniques to diagnose earlier Cystic Endometrial Hyperplasia – Pyometra complex in bitches, in order to welfare of animals.

Keywords: Bitches, CEH-Pyometra Complex, cytology, histopathology.

I. INTRODUCTION

Cystic Endometrial Hyperplasia (CEH) -Pyometra complex is a pathological condition affecting the uterus of bitches, and queens [14]. A feature of CEH -pyometra complex is presence of pus in horns of uterus, caused by different bacteria. It has been described to be prevalent in middle-aged and older bitches, especially nulliparous ones [7], [18], [3]. The most important clinical signs are anorexia, vomiting, vaginal discharge, pyrexia, etc. Vaginal discharge could be from mucopurulent to sanguineous ones if the cervix is open [18], [3]. In bitches with pyometra the leukocyte concentration in blood is elevated to 15 000–60 000/mm3 [5]. Upon histological examination uterus and its horns present large cystic endometrial glands and endometrial thickness, a lot of inflammatory cells into the glandular and uterine luminal areas and bacterial colonies [2].

The diagnosis of CEH – pyometra complex based on case history, physical examination, lab findings, ultrasonography and cytology of the vaginal discharge could be verified by histopathological examination of the uterine tissue [15].

Therefore, a better understanding of the mechanisms involved in the pathogenesis of CEH-pyometra complex in dogs and, so, for the accurate diagnosis of the disease [9].

This study was carried out to use laboratory, cytologic and pathologic findings to diagnose CEH – pyometra complex in bitches naturally affected [6].

II. MATERIALS AND METHODS

A total of 10 bitches from pure and cross breeds were included in the study. Animals were presented because of clinical symptoms of pyometra. The mean (± SE) age of the bitches was 8.33±1 year (range 1-13 years). They were presented on Pet hospital and Lab of Pathology at Agricultural University of Tirana, Faculty of Veterinary Medicine, Tirana, Albania in period of March 2018 – September 2019. History was taken and clinical examinations were performed.

Blood samples were taken from all animals for haematology (leucocyte and its formula, erythrocytes, and some of its findings (NIHON KOHDEN, CeltaC)), and biochemistry results like as urea, alkaline phosphatase, and alanine amino transferase (IDEXX Catalyst One) were performed.

Vaginal cytology was used to determine the types of epithelial cells of vagina. A cotton tip was inserted into the vagina and was pressed to the surface of the vagina lumen. It was then withdrawn and rolled on the surface of a glass slide, which drained in air and stained with Diff-Quick stain.
A nuclear, superficial, intermediate and parabasal cells were evaluated. A total of 100 cells were counted per slide.

After examination, ovariohysterectomy, under general anaesthesia, using routine surgical techniques was performed in all bitches. The tissue samples taken from different part of horns were fixed in 10% formaldehyde, embedded in paraffin, and cut in 4 μm sections, stained with Haematoxylin – Eosin, and examined with a light microscope for histopathological changes.

III. RESULTS AND DISCUSSION

In the haematological and blood biochemical examinations, there are many alterations that can be induced by pyometra [1], [16], [4]. Leucocytosis (mean 36.20±2.27), with neutrophilia and left shift are characteristic findings in pyometra together with normocytosis, normochromic anaemia, were found in this study. This normocytic, normochromic anaemia is thought to reflect the chronicity of the disease [15].

Hematologic results are given in Table I.

### TABLE I: HEMATOLOGICAL RESULTS IN BITCHES WITH CEH-PYOMETRA COMPLEX

| WBC 10^3/ml | RBC 10^3/ml | HGB g/dl | LY % | MO % | EO % | GR % |
|------------|------------|----------|-----|------|------|------|

The most important serum biochemistry finding is high level of alkaline phosphatase, (157.85±4) in our study. It is referred in approximately 50–75% of cases [8], [17]. It could be seen high level of serum alkaline phosphatase concentrations as well (282.44±1). These changes reflect hepato-cellular damage in response to toxemia or diminished hepatic circulation due to dehydration [11]. The most commonly biochemical results reported include elevated alkaline phosphatase, alanine transaminase activities, and blood urea nitrogen (BUN) [8], [7], [17]. Biochemical results are given in Table II.

B. Vaginal Cytology

Vaginal cytology in bitches with open-cervix pyometra have typically demonstrated excessive numbers of degenerate neutrophils (Fig. 1) and a highly number of parabasal cells (Results referred before (Fig. 2), [13]. Meanwhile, vaginal cytology in patients with completely closed-cervix pyometra could be used and the epithelial cells find there are parabasal cells. On the other hand, intermediate cells are decreased in this pathology. Cystic endometrial hyperplasia (CEH) – pyometra complex in the bitch is a diastral syndrome, supposed to be caused by hormonal disturbances and changes in endometrial steroid hormone receptor levels [10], [3]. It is manifested with type’ changes of epithelial cells.

![Fig. 1. Parabasal cells and an excessive degenerated neutrophil in vaginal cytology of a bitch with CEH-Pyometra complex.](image1)

C. Histopathological Examination

The bitches with CEH-Pyometra complex showed these different histological features. There are enlarged uterine glands in size and number, andrypts filled with inflammatory cells. Connective tissue was invaded by leukocyte (neutrophils) and plasma cells and (Fig. 4) and it can see vascular congestion (Fig. 4). The surface epithelium was composed of columnar cells with foamy cytoplasm (Fig. 5). These findings are referred from other authors [10], [7]. Microscopically, the most significant feature is the remarkable endometrial hyperplasia and enlarged cystic glands, in almost all cases Fig. 6. The histologic changes due to infection vary with the bacterial cause and time of infection [12].

of uterus. Histopathological diagnosis is the “gold standard” in the diagnosis of it.

This study was carried out to use some different techniques to diagnose earlier CEH – pyometra complex in bitches naturally affected, in order to a welfare of pets.
