Neutrino Masses and SO(10) SUSY GUTs

Stuart Raby\textsuperscript{a}\textsuperscript{*}

\textsuperscript{a}Department of Physics, The Ohio State University, 174 W. 18 th Ave, Columbus, Ohio 43210, USA

In this talk I discuss the qualitative features of an SO(10) SUSY GUT with an SU(2)x U(1)\textsuperscript{n} family symmetry. I then describe the global fit of this theory to precision electroweak data [including charged fermion masses and mixing angles]. Finally, the predictions of the model for neutrino masses and mixing are discussed. The most predictive version of the model naturally fits atmospheric neutrino data with maximal $\nu_\mu \rightarrow \nu_\tau$ oscillations and solar neutrino data with small mixing angle MSW $\nu_e \rightarrow \nu_{\text{sterile}}$ oscillations.

1. The Steps in Model Building

Before I discuss a particular model, let me first describe the steps one must take when constructing a candidate theory of nature.

- **List the problems**
  
  The initial step in model building requires one to analyze the experimental data and list the problems/questions left unresolved in the Standard Model. For example, we have the phenomenological/theoretical problems:
  
  1. Gauge hierarchy – $M_Z/M_{\text{Planck}} \sim 10^{-17}$
  2. Pattern of fermion masses and mixing
  3. Absence of large flavor violation

- **List the problem solving mechanisms**
  
  The next step is to obtain a list of possible mechanisms for solving the above problems. Each mechanism is capable of solving at least one (but preferably more than one) problem. Note, many known mechanisms are mutually exclusive.

- **Develop a theoretical framework**

  Finally, one develops a theoretical framework incorporating a maximal set of mutually consistent mechanisms.

  Thus prior to presenting any specific model, let us consider the list of [mechanisms/problems] we hope to incorporate into our model.

  - SUSY - a mechanism for solving the gauge hierarchy problem.
  - GUTs - for explaining charge quantization; family structure and reducing the number of fundamental parameters.
  - Textures - for obtaining the pattern of fermion masses and mixing.
  - Family Symmetry - for explaining textures; the hierarchy of family masses and solving the flavor problem.

2. The Model

The model is an $SO_{10}$ SUSY GUT with an $SU_2 \times U_1^a$ family symmetry. The three families of quarks and leptons belong to the spinor representations $16_a, 16_3$ where $a = 1, 2$ is an $SU_2$ family index.

Effective 3 x 3 Yukawa matrices are obtained at the GUT scale after spontaneously breaking the family symmetry and integrating out states with mass $(M, M_\chi)$ above $M_G$. Schematically they have the form
\[
\begin{pmatrix}
0 & \epsilon' D & 0 \\
-\epsilon' D & \epsilon C & \epsilon B \\
0 & \epsilon B & A
\end{pmatrix}
\]

where the small parameters
\[
\epsilon = \frac{\langle \phi^2 \rangle(45)}{M M_X} \approx \frac{\langle S^{22} \rangle(45)}{M M_X}
\]

\[
\epsilon' = \frac{\langle A^{12} \rangle}{M}
\]

are proportional to the family symmetry breaking vacuum values of the SO(10) singlet fields \(\phi^0, S^{ab} = S^{ba}, A^{ab} = -A^{ba}\) and the SO\(_{10}\) adjoint field 45.

2.1. Features of the Model

1. Family symmetry breaking above the GUT scale generates the hierarchy of fermion masses. In the symmetric limit, only the third generation can have mass. The mass hierarchy for the second and first generations is determined by the family symmetry breaking ratios \((\epsilon, \epsilon')\).

\[SU_2 \times U_1 \rightarrow U_1 \rightarrow \text{nothing}\]

\[\epsilon \sim \epsilon'\]

3rd family >> 2nd family >> 1st family

2. Some well known patterns for fermion masses are satisfied approximately in the model. For example, the Georgi - Jarlskog relation \(m_s \sim \frac{1}{3} m_\mu, m_d \sim 3 m_e\) \(\oplus M_G\) results from the vev of the adjoint \(\langle 45 \rangle = (B - L)M_G\) in the 22 matrix element, where \(B - L\) is baryon number minus lepton number. The same adjoint is responsible for Higgs doublet-triplet splitting.

3. Yukawa coupling unification for the third generation is well respected by the data. In particular, the relation \(\lambda_t = \lambda_b = \lambda_\tau = \lambda_{\nu_e}\) \(\oplus M_G\) gives the result \(m_t \sim 170 \pm 20\) GeV.

4. Gauge coupling unification is well respected by the data.

5. The \(SU_2\) family symmetry naturally suppresses flavor violation such as \(\mu \rightarrow e\gamma\).

6. Finally the model has only 9 arbitrary Yukawa parameters to fit 13 charged fermion masses and mixing angles. Hence there are 4 non-trivial predictions.

2.2. Global \(\chi^2\) fit to precision electroweak data

We fit the data using a global \(\chi^2\) analysis discussed originally in [3]. This analysis includes 2 loop RG running from \(M_G \rightarrow M_Z\) with the following boundary conditions at \(M_G\).

- universal squark and slepton masses - \(m_0\),
- universal gaugino masses - \(M_{1/2}\),
- non-universal \(H_u, H_d\) masses,
- \(\epsilon_3(\equiv \frac{\alpha_3 - \alpha_2}{\alpha_2})\) parameterizes the effect of one loop threshold corrections to the unification of the three gauge coupling constants at \(M_G\). Note the GUT scale is defined as the scale where \(\alpha_1 = \alpha_2\).

We also include one loop threshold corrections at \(M_Z\) to the \(Z\) and \(W\) masses and the leading corrections to the down-type quark and charged lepton masses proportional to \(\tan \beta\). We use 3 loop QCD + 1 loop QED RG running below \(M_Z\). We demand a consistent electroweak symmetry breaking solution using the one loop improved Higgs potential, including \(m_\nu^2\) corrections. Finally we construct a \(\chi^2\) function including 20 low energy observables. The result of this fit is given in the following table (for details, see [3]). Note, the observables in bold script have the largest pulls.

The parameters \(m_0, M_{1/2}\) and \(\mu\) were fixed. All others were varied using Minuit. The following are the parameters determined at \(M_G\) for the \(\chi^2\) fit in the table.

\[
(1/\alpha_G, M_G, \epsilon_3) = (24.52, 3.03 \cdot 10^{16} \text{ GeV}, -4.06\%),
(\lambda, \tau, \sigma, \epsilon, \rho, \epsilon') = (0.79, 12.4, 0.84, 0.011, 0.043, 0.0031),
(\Phi_\sigma, \Phi_\epsilon, \Phi_\rho) = (0.73, -1.21, 3.72)\text{rad},
(m_0, M_{1/2}, A_0, \mu(M_Z)) = (1000, 300, -1431, 0).$

The magnetic moment of the muon and the CP violating parameters measured in $B$ decays contain the CP violating parameters measured in $B$ decays and the SUSY contribution to the anomalous magnetic moment of the muon. Note, the charged leptons in the weak doublet $l$ are mass eigenstates and $U_e$ is the unitary matrix used to diagonalize the charged lepton mass matrix. The mass scale $M$ is not constrained and thus could be taken much larger than $M_Z$. As a consequence, the heavy sterile neutrinos may be integrated out of the theory, leaving behind the effective $3 \times 3$ neutrino mass matrix given by $m_{eff} = U_e^T M^{-1} m_e U_e$.

### 2.4. Neutrinos in SO(10)

A Dirac neutrino mass matrix $m_\nu$ given by $\nu m_\nu \bar{\nu}$ (with $\nu, \bar{\nu}$ in the 16) has already been fixed by the fits for charged fermions.

The most economical way of obtaining the seesaw (without introducing higher dimension operators) is by adding three SO(10) singlets $N$ into the superpotential as follows - 16 $N + \frac{1}{2} N M_N$ where the field $\bar{16}$ obtains a vev in the right-handed neutrino direction and $M_N$ is a mass term. Both are assumed to be of order $M_G$. This gives the effective mass terms $N V \bar{\nu} + \frac{1}{2} N M_N N$. We then obtain the 9 x 9 neutrino mass matrix at $M_G$ given by

$$
\begin{pmatrix}
\nu & \bar{\nu} & N \\
0 & m_\nu & 0 \\
m_\nu^T & 0 & V
\end{pmatrix}
$$

Upon integrating out the massive states $\bar{\nu}, N$ we obtain the effective $3 \times 3$ neutrino mass matrix - $m_{eff} = U_e^T m_\nu (V^T)^{-1} M N V^{-1} m_e U_e^*$. Now consider the particular SO(10) theory defined earlier.

### 2.5. $SO_{10} \times SU_2 \times U_1^n$ and Neutrino Masses

The three SO(10) singlets are given by $N_a, N_3$ with $a = 1,2$. The superpotential below is the most general one consistent with the family symmetries.

$$
W \supset \bar{16} (N_a \chi^a + N_3 16_3) + \frac{1}{2} N_a N_b S^a b + N_a N_3 \phi^a
$$

We now see that the effective mass matrix $M_N$ discussed above is constrained by the family sym-
metries and has the form
\[
M_N = \begin{pmatrix}
0 & 0 & 0 \\
0 & S^{22} & \phi^2 \\
0 & \phi^2 & 0
\end{pmatrix}
\]

We have analyzed several different possibilities\footnote{3}. In the simplest case, we have only three light active neutrinos. The effective 3 x 3 neutrino mass matrix is given by
\[
m^{eff}_\nu = m' U^\dagger_e \begin{pmatrix} 0 & 0 & 0 \\ 0 & b & 1 \\ 0 & 1 & 0 \end{pmatrix} U_e^* 
\]

There are only two free parameters in this matrix given by the overall scale $m'$ and $b$. Both may be taken real without affecting the observable neutrino masses and mixing angles. The zero in the 33 term is due to an accidental cancellation.

Given this neutrino mass matrix, we find that we can fit both atmospheric and LSND but NOT atmospheric and solar neutrino oscillations!!

If we want to fit both atmospheric and solar neutrino oscillations we must add a light sterile neutrino. I’ll describe how we do this next, but in the meantime let me just describe the results. We now find a solution to atmospheric neutrino oscillations with maximal $\nu_\mu \rightarrow \nu_\tau$ mixing for any value of $b \sim \frac{(S^{22})}{(\phi^2)} \leq 1$.

Given this neutrino mass matrix, we find that we can fit both atmospheric and LSND but NOT atmospheric and solar neutrino oscillations!!

If we want to fit both atmospheric and solar neutrino oscillations we must add a light sterile neutrino. I’ll describe how we do this next, but in the meantime let me just describe the results. We now find a solution to atmospheric neutrino oscillations with maximal $\nu_\mu \rightarrow \nu_\tau$ mixing and a fit to solar data given by the SMA MSW solution with $\nu_e \rightarrow \nu_{sterile}$ oscillations. Note, that even though we have four neutrinos, we are not able to fit LSND.

2.6. Sterile neutrinos in SUSY GUTs

We now argue that it is natural to have light sterile neutrinos in the MSSM. In principle any SUSY GUT could have many SO(10) singlets. The question is only whether they couple to the observable sector. Consider adding three such singlets $\tilde{N}^a, \tilde{N}^3$ with the dimensionful couplings given by
\[
W \supset \mu' N_a \tilde{N}^a + \mu_3 N_3 \tilde{N}^3
\]

The mass scales $\mu', \mu_3$ are assumed to be of order the weak scale. Via standard steps we obtain the neutrino mass matrix at $M_Z$

\[
\begin{pmatrix}
\nu & \tilde{N} & \tilde{\nu} & N \end{pmatrix} \\
\begin{pmatrix}
0 & m_\nu & 0 & 0 \\
0 & 0 & 0 & \tilde{\mu}^T \\
m^T_\nu & 0 & 0 & V \\
0 & \tilde{\mu} & V^T & M_N
\end{pmatrix}
\]

with
\[
\tilde{\mu} \equiv \begin{pmatrix} \mu' & 0 & 0 \\ 0 & \mu' & 0 \\ 0 & 0 & \mu_3 \end{pmatrix}.
\]

The effective light neutrino mass matrix $m^{eff}_\nu$ is given by
\[
m^{eff}_\nu = \tilde{U}_e^T m U_e
\]

where
\[
m = \begin{pmatrix}
m_\nu (V^T)^{-1} M_N V^{-1} m^T_{\nu} & -m_\nu (V^T)^{-1} \tilde{\mu} \\
-\tilde{\mu}^T V^{-1} m^T_{\nu} & 0
\end{pmatrix}
\]

and
\[
\tilde{U}_e = \begin{pmatrix} U_e & 0 \\ 0 & 1 \end{pmatrix}.
\]

Note we now have light sterile neutrinos and all we need do is assume that the scales $\mu', \mu_3$ are of order $M_Z$. RECALL in the MSSM we have another example of a mass term in the superpotential, $\mu$, defined via $W = \mu H_u H_d$ which must also be of order $M_Z$. What ever symmetries are needed to solve the $\mu$ problem in the MSSM could in principle also explain why our new ”mu” parameters are also of order $M_Z$.

2.7. How robust is this neutrino solution?

The four neutrino solution found above cannot fit LSND data. It is important to investigate whether this is a true prediction of the theory. In order to study this we now assume the possibility of non-minimal family symmetry breaking vevs $\langle S^{11} \rangle = \kappa_1 \langle S^{22} \rangle$, $\langle S^{12} \rangle = \kappa_2 \langle S^{22} \rangle$ with the parameters $\kappa_1, \kappa_2 << 1$\footnote{4}. In the model presented here, we are not able to find a dynamical argument why $\kappa_1 = \kappa_2 = 0$ should be an exact relation. Moreover this extension of the original model has little effect on charged fermion fits for
sufficiently small values of $\kappa_1$, $\kappa_2$. However we now find several new solutions given below. In each solution the atmospheric oscillation data is described by maximal $\nu_\mu \rightarrow \nu_\tau$ mixing.

We have a 3 $\nu$ solution with three possibilities for solar neutrinos – either SMA MSW; LMA MSW, or Vacuum $\nu_e \rightarrow \nu_{\text{active}}$ oscillations. In addition we have 4 $\nu$ and 5 $\nu$ solutions with solar data given by SMA MSW $\nu_e \rightarrow \nu_{\text{sterile}}$ oscillations and LSND given by $\nu_e \rightarrow \nu_\mu$.

3. Conclusions

The theoretical framework presented here provides a compact and precise description of low energy data. With regards to neutrino masses and mixing we have two possibilities –

- In a “predictive” theory (with sufficient symmetry to enforce a small number of arbitrary parameters) neutrino masses are very constrained. In this case, charged fermion masses and mixing angles can strongly constrain the neutrino sector.

  For example, an $SO_{10} \times D_3 \times Z_M$ model provides a natural framework for the case of minimal family symmetry breaking vevs.

- If there are however many free parameters, then neutrino masses and mixing are poorly constrained by the charged fermion sector.

Finally we have not presented a complete theory here. There are still many unresolved problems: SUSY breaking, GUT breaking, family symmetry breaking, $\mu$ problem, strong CP problem.
