ELLIPTIC FIBRATIONS ON COVERS OF THE ELLIPTIC MODULAR SURFACE OF LEVEL 5

FRANCESCA BALESTRIERI, JULIE DESJARDINS, ALICE GARBAGNATI, CÉLINE MAISTRET, CECÍLIA SALGADO, AND ISABEL VOGT

Abstract. We consider the K3 surfaces that arise as double covers of the elliptic modular surface of level 5, \( \mathcal{R}_{5,5} \). Such surfaces have a natural elliptic fibration induced by the fibration on \( \mathcal{R}_{5,5} \). Moreover, they admit several other elliptic fibrations. We describe such fibrations in terms of linear systems of curves on \( \mathcal{R}_{5,5} \). This has a major advantage over other methods of classification of elliptic fibrations, namely, a simple algorithm that has as input equations of linear systems of curves in the projective plane yields a Weierstrass equation for each elliptic fibration. We deal in detail with the cases for which the double cover is branched over the two reducible fibers of type \( I_5 \) and for which it is branched over two smooth fibers, giving a complete list of elliptic fibrations for these two scenarios.

1. Introduction

Let \( S/\mathcal{C} \) be a smooth projective surface and \( B/\mathcal{C} \) be a smooth projective curve. We say that a proper flat map \( \mathcal{E}: S \to B \) is an elliptic fibration if the generic fiber \( S_b \) is a smooth genus 1 curve and a section \( O: B \to S \) is given. Given a section, we regard the generic fibre of \( \mathcal{E} \) as an elliptic curve over the function field \( k(B) \) and so we can work with a Weierstrass form of \( \mathcal{E} \). We will say that an elliptic fibration is relatively minimal if there are no contractible curves contained in its fibers. For the remainder of this paper all elliptic fibrations will be assumed to be relatively minimal and not of product type.

Not all surfaces \( S \) admit elliptic fibrations and if \( S \) admits an elliptic fibration, a lot is known about the base curve and about the maximal number of elliptic fibrations on it. More precisely if \( S \) is of general type, then \( S \) admits no elliptic fibrations; if the Kodaira dimension of \( S \) is non-positive, then the curve \( B \) is rational; if a surface \( S \) admits more than one elliptic fibration as above, then it is a K3 surface (a surface with trivial canonical bundle and trivial irregularity). In particular if \( S \) is either a K3 surface or a rational surface, then \( B \simeq \mathbb{P}^1 \). Every relatively minimal rational elliptic surface is the total space of a pencil of plane cubics; such surfaces admit only the obvious elliptic fibration. We refer to [6] and to [11] for more on the theory of elliptic fibrations on surfaces.

1.1. K3 surfaces arising from rational elliptic surfaces, and their elliptic fibrations. In this paper we will consider K3 surfaces \( S \) that are double covers of rational elliptic surfaces \( R \), branched over two fibers of the elliptic fibration \( \mathcal{E}_R : R \to \mathbb{P}^1 \). More precisely, such K3 surfaces are the minimal resolution of the fiber product \( \overline{S} \) of a rational elliptic surface \( \mathcal{E}_R : R \to \mathbb{P}^1 \) and a degree two
map \( \mathbb{P}^1 \to \mathbb{P}^1 \), which is necessarily branched over two points. We recall that an involution on a K3 surface is non-symplectic if it acts by \(-1\) on \(H^0(S, K_S) \simeq \mathbb{C}\). Call \( \iota \) the involution on \( S \) agreeing with the cover involution of the \(2:1\) map \( \overline{S} \to R \); then this involution is non-symplectic and fixes the inverse image of two fibers of the fibration \( \mathcal{E}_R : R \to \mathbb{P}^1 \), which are the branch curves. The quotient surface \( S/\iota \) is rational and is either \( R \) or a blow-up of \( R \) (denoted by \( \tilde{R} \) in what follows).

It was proved by Zhang (see [15]) that every K3 surface \( S \) admitting a non-symplectic involution \( \iota \) whose fixed locus contains curves of genus at most 1 arises by a base change of order two from a rational elliptic fibration \( \mathcal{E}_R : R \to \mathbb{P}^1 \) as described above.

The K3 surface \( S \) obtained as above is naturally equipped with one elliptic fibration \( \mathcal{E}_S : S \to \mathbb{P}^1 \), induced via pullback from \( \mathcal{E}_R \). In [4] the relationship between elliptic fibrations on \( S \) and linear systems on the rational surface \( R \) (or \( \tilde{R} \)) is studied. The elliptic fibrations on \( S \) fall into one of the three categories below according to the action of \( \iota \) on the fibers. Note that \( \mathcal{E}_S \) belongs to the second one:

- if \( \iota \) preserves each fiber of the fibration, then it acts on the fibers as the elliptic involution. The elliptic fibration on \( S \) is therefore induced by fibrations in rational curves on \( \tilde{R} \). We will call these pencils “conic bundles” if they are rational fibrations on \( R \) and “generalized conic bundles” if they are rational fibrations on \( \tilde{R} \) (but not on \( R \));

- if \( \iota \) preserves the fibration, but not each fiber of the fibration, this implies that \( \iota \) acts on the base of the fibration (with two fixed points). In this case the elliptic fibration on \( S \) is induced by a pencil of genus 1 curves on \( R \), whose members split in the double cover. We call these pencils “splitting genus 1 pencils”;

- if \( \iota \) does not preserve the elliptic fibration, we call the fibration of type 3. A fibration is of type 3 if and only if the class of the fiber of the fibration, in the Néron-Severi group of \( S \), is not preserved by \( \iota \).

As a result of this classification and of the technique introduced in [4], in good cases one may classify the singular fibers of all elliptic fibrations \( \mathcal{E} : S \to \mathbb{P}^1 \) in terms of the singular fibers of more tractable linear series on \( S/\iota \). Our focus here is on even finer information: obtaining explicit Weierstrass equations of elliptic fibrations on such K3 surfaces. Using Tate’s algorithm, one may then read off the singular fibers from the order of vanishing of the coefficients and discriminant of the Weierstrass equation (see, for example, the table on page 41 of [6]). In Sections 5.2 and 6.1.2 we give methods and algorithms for determining Weierstrass equations coming from conic bundles and splitting genus 1 pencils on rational elliptic surfaces, under some assumptions. This is our main result.

**Theorem 1.1.** Let \( S \) be a K3 surface arising from the rational elliptic surface \( \mathcal{E}_R : R \to \mathbb{P}^1 \) as described above. Let \( \mathcal{E} \) be an elliptic fibration on \( S \) that is not of type 3. Then, under certain conditions, one obtains a Weierstrass equation for \( \mathcal{E} \) by applying

- the Algorithm of Section 5.2 if \( \mathcal{E} \) is induced by a (generalized) conic bundle with prescribed properties (see Section 5.2 for details);

- the Algorithm of Section 6.1.2 if \( \mathcal{E} \) is induced by a splitting genus 1 pencil.

**1.2. Outline of the paper.** We focus particularly on K3 surfaces arising as double covers of \( R_{5,5} \), the elliptic modular surface of level 5. This is the universal elliptic curve over the modular curve \( X_1(5) \) and the evident map \( \mathcal{E}_{R_{5,5}} : R_{5,5} \to X_1(5) \simeq \mathbb{P}^1 \).
is the unique elliptic fibration. The fibers of $\mathcal{E}_{R_{5,5}}$ are smooth except for two nodal rational curves (type $I_1$) and two 5-gons (type $I_5$); this property also determines $R_{5,5}$ and implies that the Mordell-Weil group $\text{MW}(\mathcal{E}_R) = \mathbb{Z}/5\mathbb{Z}$. The geometry of this surface as the total space of a pencil of plane cubics is described in Section 2.

In Section 3 we classify the conic bundles on $R_{5,5}$ up to automorphisms. The main result of this Section is Proposition 3.1.

In the remainder of the paper we study elliptic fibrations on different K3 surfaces arising from $R_{5,5}$ by choosing different base changes. In Section 4 we describe such K3 surfaces, writing their equations as double covers of $\mathbb{P}^2$, as well as giving the Weierstrass form of the elliptic fibrations induced by $\mathcal{E}_R$.

In Section 5 we consider the elliptic fibrations induced on K3 surfaces by the conic bundles classified in Section 3. We observe directly that the same conic bundle induces elliptic fibrations with very different properties on K3 surfaces according to the choice of the branch curves. In Sections 6 and 7 we restrict our attention to two K3 surfaces obtained by choosing maximally different branch fibers: in Section 6 we consider the very special case where the branch fibers are $2I_5$ and in Section 7 we consider the generic case where the branch fibers are $2I_0$.

When the double cover is branched over the two 5-gons, the K3 surface is called $S_{5,5}$ and the involution $\iota$ fixes the union of 10 rational curves. There is a unique such K3 surface possessing such a non–symplectic involution. This K3 surface admits 13 types of elliptic fibrations, classified by Nishiyama in [9]. In this special case we are able to determine equations for all elliptic fibrations on $S_{5,5}$ using our techniques and algorithms. We observe that in this case there are no fibrations of type 3. The main result of this Section is Proposition 6.1.

When the double cover is branched on two smooth fibers, the K3 surface moves in the 2-dimensional family of the K3 surfaces admitting an elliptic fibration with a 5-torsion section. We call a very general member of this family $X_{5,5}$ and using the lattice-theoretic technique of [9] we list all the admissible configurations of fibers of an elliptic fibration on $X_{5,5}$ in Table 7.1 proving Proposition 7.1. In this case the elliptic fibrations cannot be induced by splitting genus 1 pencils or by generalized conic bundles. On the other hand there are plenty of elliptic fibrations of type 3 and we describe one of them in detail.

Acknowledgements. This work was initiated during the Women in Numbers Europe 2 workshop. We thank the organizers and the Lorentz Center in Leiden for providing such a stimulating research environment. We also thank Bernd Sturmfels for drawing our attention to the connections with tropical geometry, and the referee for many helpful suggestions and comments that have improved this article.

2. The surface $R_{5,5}$

Let $R_{5,5}$ be the elliptic modular surface of level 5. We know from [1 Tableau] (with coordinates $X = x_0, Y = x_0 - x_1, Z = x_2$) that the surface $R_{5,5}$ is the blow-up of $\mathbb{P}^2$ in the basepoints of the pencil $\mathcal{P}$ of cubics

$$\lambda x_1 x_2 (x_0 - x_1) + \mu x_0 (x_0 - x_1 - x_2) (x_0 - x_2) = 0.$$  

We will denote this blow-up morphism by $\beta: R_{5,5} \to \mathbb{P}^2$. The cubic corresponding to $\lambda = 0$ is reducible and consists of the three lines $m_1 : x_0 = 0, m_2 : x_0 - x_1 - x_2 = 0, m_3 : x_0 - x_2 = 0$; the cubic corresponding to $\mu = 0$ is reducible and consists of the three lines $\ell_1 : x_0 - x_1 = 0, \ell_2 : x_1 = 0, \ell_3 : x_2 = 0$. 

The nine basepoints of this pencil of cubics are: $Q_1 := (0 : 0 : 1)$; the point $Q'_1$, infinitely near to $Q_1$ and corresponding to the tangent direction $m_1$; $Q_2 := (1 : 1 : 0)$; the point $Q'_2$, infinitely near to $Q_2$ and corresponding to the tangent direction $m_2$; $Q_3 := (0 : 1 : 0)$; the point $Q'_3$, infinitely near to $Q_3$ and corresponding to the tangent direction $\ell_2$; $Q_4 := (1 : 0 : 1)$; the point $Q'_4$, infinitely near to $Q_4$ and corresponding to the tangent direction $\ell_2$; $Q_5 := (1 : 1 : 1)$.

In the following we will denote by $T_1$ the point $(1 : 0 : 0)$, which is not a basepoint of the pencil and corresponds to the intersection of the lines $\ell_2$ and $\ell_3$, and by $T_2$ the point $(0 : 1 : -1)$, which is not a basepoint of the pencil and corresponds to the intersection of the lines $m_1$ and $m_2$.

Let $h$ denote the preimage of the class of a line; then $\text{NS}(R_{5,5})$ is spanned by $h$ and the components of the exceptional divisors of the blow up $\beta : R_{5,5} \to \mathbb{P}^2$. We will denote the (irreducible) exceptional divisor corresponding to $Q_i$ (resp. $Q'_i$) by $E_i$ (resp. $F_i$) for $i = 1, 2, 3, 4$. At $Q_5$ there is only $E_5$. Note that $F_i^2 = -1$, $E_i^2 = -2$ for $i = 1, 2, 3, 4$, $E_2^2 = -1$, $E_iE_j = 0$ if $i \neq j$, $F_iF_j = 0$ if $i \neq j$, $E_iF_i = 1$. By slight abuse of notation, let $\ell_1, \ell_2, \ell_3$ and $m_1, m_2, m_3$ denote the proper transforms on $R_{5,5}$ of the corresponding lines in $\mathbb{P}^2$. We have the following relations in $\text{NS}(R_{5,5})$:

\begin{align*}
\ell_1 &= h - E_1 - F_1 - E_2 - F_2 - E_5 & m_1 &= h - E_1 - 2F_1 - E_3 - F_3 \\
\ell_2 &= h - E_1 - F_1 - E_4 - 2F_4 & m_2 &= h - E_2 - 2F_2 - E_4 - F_4 \\
\ell_3 &= h - E_1 - F_1 - E_3 - 2F_3 & m_3 &= h - E_3 - F_3 - E_4 - F_4 - E_5.
\end{align*}

The Weierstrass equation of the elliptic fibration of $R_{5,5}$ is obtained by choosing $x_2 = 1$ and applying standard transformations. It is

\begin{equation}
y^2 = x^3 + A(\lambda : \mu)x + B(\lambda : \mu),
\end{equation}

where

\begin{align*}
A(\mu) := & \frac{-1}{48}\mu^4 - \frac{1}{4}\mu^3\lambda - \frac{7}{24}\mu^2\lambda^2 + \frac{1}{4}\mu\lambda^3 - \frac{1}{48}\lambda^4, \\
B(\mu) := & \frac{1}{864}\mu^6 + \frac{1}{48}\mu^5\lambda + \frac{25}{288}\mu^4\lambda^2 + \frac{25}{288}\mu^3\lambda^3 - \frac{1}{48}\mu\lambda^4 + \frac{1}{864}\lambda^6.
\end{align*}
The discriminant is \frac{1}{16}n^5\lambda^5(-\lambda^2 + 11\mu\lambda + \mu^2), so there are two fibers of type \(I_5\) over \((\lambda : \mu) = (0 : 1)\) and \((\lambda : \mu) = (1 : 0)\). Moreover there are two fibers of type \(I_1\) over \((\lambda : \mu) = (1 : -\frac{15}{2} \pm \frac{5}{2}\sqrt{5})\).

Now the function
\[
\mu \mapsto (x(\lambda : \mu); y(\lambda : \mu)) = \left(\frac{\mu^2 - 6\mu\lambda + \lambda^2}{12}, \frac{\mu^2\lambda}{2}\right)
\]
is a 5-torsion section of this fibration. It is known, see e.g. [11, Section 9.5] that the elliptic fibration on \(R_{5,5}\) has Mordell–Weil group equal to \(\mathbb{Z}/5\mathbb{Z}\).

The negative curves on \(R_{5,5}\) are

1. the ten components of the two fibers of type \(I_5\) denoted by \(\Theta_0^{(1)}, \Theta_1^{(1)}, \Theta_2^{(1)}, \Theta_3^{(1)}, \Theta_4^{(1)}\) on the first fiber and \(\Theta_0^{(2)}, \Theta_1^{(2)}, \Theta_2^{(2)}, \Theta_3^{(2)}, \Theta_4^{(2)}\) on the second fiber (these are all \((-2)\)-curves);
2. the five sections \(P_0, P_1, P_2, P_3, P_4\), where \(P_0\) meets the components \(\Theta_0^{(1)}\) and \(\Theta_0^{(2)}, P_1\) meets the components \(\Theta_1^{(1)}\) and \(\Theta_2^{(2)}, P_2\) meets the components \(\Theta_2^{(1)}\) and \(\Theta_4^{(2)}, P_3\) meets the components \(\Theta_3^{(1)}\) and \(\Theta_1^{(2)}\) and \(P_4\) meets the components \(\Theta_4^{(1)}\) and \(\Theta_3^{(2)}\) (these sections are all \((-1)\)-curves).

The dual graph of this configuration is given in Figure 2. We observe that the Figure 2 is a generalization of the Petersen graph (it is exactly the Petersen graph if one does not consider the empty edges) and we point out that this graph represents several intersecting objects in algebraic geometry and in tropical geometry, see e.g. [10].

![Dual graph of negative curves on R_{5,5}](image)

Figure 2. Dual graph of negative curves on \(R_{5,5}\). The symbol • denotes a \((-2)\)-curve, and • denotes a \((-1)\)-curve.

We may then make the following choice of identifications:

\[
\begin{align*}
\Theta_0^{(1)} &= m_1 & \Theta_1^{(1)} &= E_3 & \Theta_2^{(1)} &= m_3 & \Theta_3^{(1)} &= E_4 & \Theta_4^{(1)} &= m_2 \\
P_0 &= F_1 & P_1 &= F_3 & P_2 &= E_5 & P_3 &= F_4 & P_4 &= F_2.
\end{align*}
\]

We observe that there is an automorphism \(\sigma_5\) on \(R_{5,5}\) of order 5, which is the translation by the section \(P_1\). It acts on the negative curves as follows: \(\sigma_5(\Theta_i^{(1)}) = \)
\[ \Theta_{i}^{(1)} \] and \( \sigma_5(\Theta_{i}^{(2)}) = \Theta_{i+2}^{(2)} \), where \( i + 1 \) and \( i + 2 \) are considered modulo 5; \( \sigma_5(P_k) = P_{k+1} \), where \( k + 1 \) is considered modulo 5.

There is also an automorphism \( \sigma_2 \) of order 2 on \( \mathbb{R}_{5,5} \), which is the elliptic involution on the elliptic curve (2.3) over the function field \( k(\mu) \). Note that \( \sigma_2 \) restricts to the elliptic involution on each smooth fiber of the fibration (2.3). It acts on the negative curves as follows:

\[ \sigma_2(\Theta_{j}^{(i)}) = \Theta_{-i}^{(1)} \]

where \( i \in \mathbb{Z}/5\mathbb{Z} \), \( j = 1, 2 \) and \( \sigma_2(P_k) = P_{-k} \), where \( k \in \mathbb{Z}/5\mathbb{Z} \).

There is also an automorphism \( \alpha \) of \( \mathbb{R}_{5,5} \) lying above the involution of \( \mathbb{P}^1 \alpha: (\lambda : \mu) \mapsto (-\mu : \lambda) \). In terms of the Weierstrass equation (2.3), we have:

\[ \alpha: (x, y, \mu) \mapsto (x/\mu^2, -y/\mu^3, -1/\mu). \]

Note that the automorphism \( \sigma_2^3 \alpha \sigma_2^3 \) is induced by the element \( \left( \begin{array}{ccc} \ 0 & 1 & 0 \\ -1 & 1 & 1 \\ -1 & 0 & 0 \end{array} \right) \in \text{PGL}_3(\mathbb{C}) \).

From this description, the action on \( \text{NS}(\mathbb{R}_{5,5}) \) is apparent:

\[ \alpha(\Theta_{i}^{(1)}) = \Theta_{i}^{(2)} \] and \( \alpha(\Theta_{i}^{(2)}) = \Theta_{-i}^{(1)} \).

Finally \( \Theta(P_0) = P_0 \) while the remaining sections are permuted so as to preserve intersections.

3. Conic Bundles on \( \mathbb{R}_{5,5} \)

In this section we classify the conic bundles on \( \mathbb{R}_{5,5} \) by considering their reducible fibers proving Proposition 3.1.

The key result we use is that on a rational elliptic surface, every conic bundle has at least one reducible fiber. Further, any reducible fiber must be of type \( A_n \) or \( D_m \), as shown in Figure 3, see e.g. [4].

![Figure 3](image)

**Figure 3.** Possible reducible fibers of conic bundles on (minimal) rational elliptic surfaces. The number \( n \) and \( m \) refer to the number of components. Multiplicity of a component is indicated above the corresponding vertex if it is not 1. The symbol \( \bullet \) denotes a \((-2)\)-curve, and \( \circ \) denotes a \((-1)\)-curve.

**Proposition 3.1.** There are exactly three conic bundles on \( \mathbb{R}_{5,5} \) up to automorphisms, i.e. the conic bundles \( B_1 \), \( B_2 \) and \( B_3 \) induced by the pencils of plane rational curves with equations (3.1), (3.2) and (3.3) respectively.

**Proof.** **Step 1:** classification of the reducible fibers. Every conic bundle has at least one reducible fiber, so in order to classify the conic bundles it suffices to find all the possible reducible fibers. The components of the reducible fibers are negative curves. As \( \mathbb{R}_{5,5} \) (and in fact any extremal rational elliptic surface, see [6 VIII.1.2]) has only finitely many curves of negative self-intersection, one simply must find all possible \( A_n \) and \( D_m \) (for \( m \geq 3 \)) configurations among the curves with negative self intersection.

Every reducible fiber contains at least a \((-1)\)-curve, as shown in Figure 3. Since we are looking for a classification up to automorphisms, and the automorphism \( \sigma_5 \)
permutes the $(-1)$-curves on $R_{5,5}$, we can always assume that one of the reducible fibers of the conic bundle contains the $(-1)$-curve $P_0$. Moreover we recall that the action of $\sigma_2$ switches $\Theta_i^{(j)}$ with $\Theta_{2i-1}^{(j)}$ and the action of $\alpha$ switches the two $I_5$-fibers. Up to the action of $\sigma_2$ and $\alpha$, the reducible fibers of type $A_n$ that contain $P_0$ as a component are necessarily of the following type:

- $P_0 + \sum_{i=0}^k \Theta_i^{(1)} + P_k$, $k = 1, 2, 3$ and in this case we have a fiber of type $A_{k+3}$.

Up to the action of $\sigma_2$ the reducible fibers of type $D_m$ that contain $P_0$ as a component are necessarily of the following types:

- $2P_0 + \Theta_0^{(1)} + \Theta_0^{(2)}$ and in this case we have a fiber of type $D_3$;
- $2P_0 + 2\Theta_0^{(1)} + \Theta_1^{(1)} + \Theta_1^{(3)}$ and in this case we have a fiber of type $D_4$.

**Step 2: At most three conic bundles.** We consider the conic bundles associated to the possible singular fibers described above and show that some of them are equivalent up to the action of $\sigma_5$ and $\sigma_2$. Moreover we describe the conic bundles that we find and we give equations for them:

- $|B_1| = |P_0 + \Theta_0^{(1)} + \Theta_0^{(1)} + P_1|$. The components of one reducible fiber are $P_0$, $\Theta_0^{(1)}$, $P_1$. This fiber is of type $A_1$. The curves $\Theta_1^{(1)}$, $\Theta_1^{(3)}$, $\Theta_0^{(2)}$ and $\Theta_0^{(2)}$ are sections of the bundle. There is another reducible fiber of type $A_4$ which is formed by the curves $P_2$, $\Theta_2^{(2)}$, $\Theta_3^{(2)}$, $P_4$, and one of type $D_3$ which is formed by $P_3$ (with multiplicity 2), $\Theta_3^{(1)}$, $\Theta_3^{(2)}$.

Using the identifications made earlier, this class can also be written as:

$$B_1 = F_1 + m_1 + E_3 + F_3 = F_1 + (h - E_1 - 2F_1 - E_3 - F_3) + E_3 + F_3 = h - E_1 - F_1.$$ 

Unwinding what this means geometrically: $|B_1|$ comes via proper transform from the pencil of lines through $Q_1$ in $\mathbb{P}^2$ which has equation

$$x_1 = \tau x_0.$$ 

Under this description we can also understand the singular fibers: they correspond to the special lines $m_1, \ell_1$, and $\ell_2$. For example the line $\ell_2$ corresponds to the reducible fiber $\beta^*(\ell_2) - E_1 - F_1 = \ell_2 + E_4 + 2F_4 = \Theta_1^{(2)} + \Theta_3^{(2)} + 2P_3$.

The conic bundle $|B_1|$ is sent to other conic bundles by $\sigma_5$, by $\sigma_2$ and by their powers. Each of these has exactly three reducible fibers of types $A_4$, $A_4$ and $D_3$.

We observe that the fiber of type $D_3$ of the conic bundle $|B_1|$ is sent to $2P_0 + \Theta_0^{(1)} + \Theta_0^{(2)}$ by the automorphism $\sigma_3^2$, so the conic bundle with reducible fiber $2P_0 + \Theta_0^{(1)} + \Theta_0^{(2)}$ is equivalent to $|B_1|$ up to automorphisms. Similarly the $A_4$-fiber $P_2 + \Theta_4^{(2)} + \Theta_3^{(2)} + P_4$ is sent to $P_3 + \Theta_1^{(2)} + \Theta_0^{(2)} + P_0$ by $\sigma_5$, so also the conic bundle with reducible fiber $P_0 + \Theta_0^{(2)} + \Theta_1^{(2)} + P_3$ is equivalent to $|B_1|$ up to automorphisms.

- $|B_2| = |P_0 + \Theta_0^{(1)} + \Theta_1^{(1)} + \Theta_2^{(1)} + P_2|$. The components of one reducible fiber are $P_0$, $\Theta_0^{(1)}$, $\Theta_1^{(1)}$, $\Theta_2^{(1)}$, $P_2$. This fiber is of type $A_5$. The curves $\Theta_3^{(1)}$, $\Theta_4^{(1)}$, $\Theta_0^{(2)}$, $\Theta_4^{(2)}$ and $P_1$ are sections of the bundle. There is another reducible fiber of type $A_5$ which is formed by the curves $P_3$, $\Theta_2^{(2)}$, $\Theta_3^{(2)}$, $P_4$.

Similarly here we can write:

$$B_2 = F_1 + m_1 + E_3 + m_3 + E_5 = 2h - E_1 - F_1 - E_3 - 2F_3 - E_4 - F_4.$$
Hence $B_2$ corresponds to the pencil of conics through $Q_1, Q_3, Q'_3$, and $Q_4$. More explicitly this is given by conics passing through $Q_1$ and $Q_4$, and tangent to $\ell_3$ at $Q_3$ and in $\mathbb{P}^2$ this pencil is given by the equation
\[ x_1x_2 = \tau(x_0x_2 - x_0^2). \]
The two reducible fibers correspond to the reducible conics $m_1 \cup m_2$ and $\ell_2 \cup \ell_3$.

The $A_5$-fiber of $[B_2]$ whose components are $P_3, \Theta_1^{(2)}, \Theta_2^{(2)}, \Theta_3^{(2)}, P_4$ is sent to the reducible fiber $\sum_{i=0}^4 \Theta_i^{(2)} + P_1$ by $\sigma_5^2$.

(3) $|B_3| = |P_0 + \Theta_0^{(2)} + \Theta_1^{(2)} + \Theta_2^{(2)} + \Theta_3^{(2)} + P_3|$. The components of one reducible fiber are $P_0, \Theta_0^{(2)}, \Theta_1^{(2)}, \Theta_2^{(2)}, \Theta_3^{(2)}, P_3$. This fiber is of type $A_6$. The curves $\Theta_0^{(2)}, \Theta_1^{(2)}, P_1$ and $P_2$ are sections of the bundle. The curve $\Theta_4^{(2)}$ is a multisection of degree 2. There is another reducible fiber of type $D_4$ which is formed by the curves $P_4, \Theta_1^{(2)}, \Theta_4^{(2)}, \Theta_2^{(2)}$.

We can also describe this using:
\[ B_3 = F_1 + m_1 + E_3 + m_3 + E_4 + F_4 = 2h - E_1 - F_1 - E_3 - 2F_3 - E_5. \]

Therefore $B_3$ comes from the pencil of conics in $\mathbb{P}^2$ through $Q_1, Q_3, Q'_3$ and $Q_5$; that is conics through $Q_1$ and $Q_5$, tangent to $\ell_3$ at $Q_3$, and in $\mathbb{P}^2$ this pencil is given by the equation
\[ x_1x_2 = (\tau + 1)x_0x_2 - \tau x_0^2. \]
We can again understand the reducible fibers as coming from reducible conics $\ell_1 \cup \ell_3$ and $m_1 \cup m_3$.

The $D_4$-fiber is sent to the fiber $2P_0 + 2\Theta_0^{(2)} + \Theta_1^{(2)} + \Theta_4^{(2)}$ by $\sigma_5$.

**Step 3: exactly three conic bundles.** It remains only to prove that the conic bundles $B_i$ for $i = 1, 2, 3$ are all inequivalent up to automorphisms. Since the reducible fibers of $|B_1|$ are $(2A_4, D_3)$, the reducible fibers of $|B_2|$ are $(2A_5)$ and the reducible fibers of $|B_3|$ are $(A_6, D_4)$, they cannot be equivalent up to automorphisms. Hence there are three conic bundles on $R_{5,5}$ up to automorphisms.

\[ \square \]

4. K3 surfaces obtained by $R_{5,5}$

Now we consider K3 surfaces obtained from $R_{5,5}$ by a base change of order 2 branched on two fibers. Of course the K3 surface obtained depends on the branch fibers. Let us explicitly give the description of the K3 surfaces that we can obtain in this way. They will be both described as elliptic fibrations (induced by the one of $R_{5,5}$) and as double covers of $\mathbb{P}^2$.

4.1. The branch fibers are 2$I_5$: the K3 surface $S_{5,5}$. Let us consider the K3 surface $S_{5,5}$ obtained by a base change of order 2 of $R_{5,5}$ whose branch locus corresponds to the two fibers of type $I_5$. This means that all the components of the fibers of type $I_5$ are in the branch locus of the double cover $S_{5,5} \rightarrow R_{5,5}$.

4.1.1. The surface $\widetilde{R}$. The double cover of $R_{5,5}$ branched over the two fibers of type $I_5$ has ordinary double point singularities at the 10 points over the nodes in the branch fibers. In order to obtain a K3 surface one can blow-up these 10 points on the double cover, introducing 10 exceptional divisors. Equivalently one may first blow-up the 10 nodes of the branch fibers to obtain a non-minimal rational elliptic surface $\tilde{R}$ and then normalize the double cover of this surface branched over
by respectively $E_i$, $F_i$, $G_i$ and $H_i$ the four exceptional divisors over $Q_i$ for $i = 1, 2, 3, 4$. For each $i$, the divisor $E_i$ is a $(-4)$-divisor intersecting $F_i$, $G_i$, and $H_i$, which are orthogonal $(-1)$-curves. We make the identification that $F_i$ is the tangent direction corresponding to the basepoint of the pencil of cubics, and $H_i$ and $G_i$ correspond to the tangent directions specified in the following table:

| $i$ | 1 | 2 | 3 | 4 |
|-----|---|---|---|---|
| $G_i$ | $\ell_1$ | $\ell_3$ | $m_1$ | $m_3$ |
| $H_i$ | $\ell_2$ | $\ell_1$ | $m_3$ | $m_2$. |

Note that the $E_i$ and $F_j$ are the strict transforms of the curves of the same name on $\overline{R}_{5,5}$.

The strict transforms of the lines $\ell_j$ and $m_j$, $j = 1, 2, 3$ on $\overline{R}$ are the following:

| $j$ | $\ell_j$ | $m_j$ |
|-----|---------|-------|
| 1   | $h - E_1 - F_1 - 2G_1 - H_1 - E_2 - F_2 - G_2 - 2H_2 - EQ_5$; | $h - E_1 - F_1 - 2G_1 - H_1 - E_2 - F_2 - G_2 - 2H_2 - EQ_5$; |
| 2   | $h - E_1 - F_1 - G_1 - 2H_1 - E_2 - 2F_2 - 4G_1 - H_1 - E_1; | $h - E_1 - F_1 - G_1 - 2H_1 - E_2 - 2F_2 - 4G_1 - H_1 - E_1; |
| 3   | $h - E_2 - F_2 - 2G_2 - H_2 - E_3 - 2F_3 - G_3 - H_3 - E_1; | $h - E_2 - F_2 - 2G_2 - H_2 - E_3 - 2F_3 - G_3 - H_3 - E_1; |
| 4   | $h - E_1 - 2F_1 - G_1 - H_1 - E_2 - F_2 - G_2 - 2H_2 - EQ_5$; | $h - E_1 - 2F_1 - G_1 - H_1 - E_2 - F_2 - G_2 - 2H_2 - EQ_5$; |
| 5   | $h - E_2 - 2F_2 - G_2 - H_2 - E_1 - F_1 - G_4 - 2H_4 - E_1; | $h - E_2 - 2F_2 - G_2 - H_2 - E_1 - F_1 - G_4 - 2H_4 - E_1; |
| 6   | $h - E_3 - F_3 - G_3 - 2H_3 - E_4 - F_4 - 2G_4 - H_4 - EQ_5$. | $h - E_3 - F_3 - G_3 - 2H_3 - E_4 - F_4 - 2G_4 - H_4 - EQ_5$. |

The sections of the non–relatively minimal fibration on $\overline{R}$ are $F_j$, $j = 1, 2, 3, 4$ and $E_{Q_5}$ (i.e. the strict transform of the sections of the fibration on $R_{5,5}$).

4.1.2. Geometric description of $S_{5,5}$ and its Néron–Severi group. The surface $S_{5,5}$ admits a non-symplectic involution $\iota$ which is the cover involution of the double cover $S_{5,5} \to \overline{R}$. This involution fixes 10 rational curves (the curves $m_i$, $\ell_{i,j}$ and $E_j$ with $j = 1, 2, 3, 4$) and it acts trivially on the Néron–Severi group.

The elliptic fibration $\mathcal{E}_{S_{5,5}}$: $S_{5,5} \to \mathbb{P}^1$ induced by $\mathcal{E}_{R_{5,5}}$: $R_{5,5} \to \mathbb{P}^1$ has two fibers of type $I_{10}$ (induced by the fibers of type $I_5$ on $R_{5,5}$) and four other singular fibers, all of type $I_1$. The trivial lattice of the fibration (generated by the class of the generic fiber, the class of the zero section and the classes of the non trivial components of the reducible fibers) has rank 20. The trivial lattice is a sublattice of the Néron–Severi group, and since the Néron–Severi group of a K3 surface has rank at most 20, we conclude that it is exactly 20. By the Shioda–Tate formula there are no sections of infinite order for the fibration $\mathcal{E}_{S_{5,5}}$: $S_{5,5} \to \mathbb{P}^1$. The 5-torsion sections of the fibration on $R_{5,5}$ induce 5-torsion sections of $\mathcal{E}_{S_{5,5}}$. Hence, $\text{MW}(\mathcal{E}_{S_{5,5}}) \supseteq \mathbb{Z}/5\mathbb{Z}$. The possible torsion parts of the Mordell–Weil group of an elliptic fibration on a K3 surface are $\mathbb{Z}/n\mathbb{Z}$ for $2 \leq n \leq 8$, and $\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/m\mathbb{Z}$, for $m = 2, 4, 6$, $(\mathbb{Z}/k\mathbb{Z})^2$ for $k = 3, 4$ (see for example [12 Thm 7.1]). So we conclude that $\text{MW}(\mathcal{E}_{S_{5,5}}) = \mathbb{Z}/5\mathbb{Z}$.
The curves $\Theta_{i}^{(j)}$ are in the branch locus and we denote by $\Omega_{i}^{(j)}$ the rational curve on $S_{5,5}$ which maps $1 : 1$ to $\Theta_{i}^{(j)}$. Moreover, we have 10 other rational curves on $S_{5,5}$: the curves $\Omega_{i_1,i_1 - 1}^{(j)}$, for $i_1, i_1 - 1 \in \mathbb{Z}/5\mathbb{Z}$, $j = 1, 2$, which are the curves resolving the singularities of the intersection point between $\Theta_{\pi_1}^{(j)}$ and $\Theta_{\pi_2}^{(j)}$ and are the double cover of the 10 exceptional curves of the blow up $\tilde{R} \to R_{5,5}$. The curves $P_i$ are not in the branch locus and we denote by $Q_i$ their $2 : 1$ cover in $S_{5,5}$. The dual graph of this configuration is given in Figure 4. We observe that this gives exactly the diagram given in [13, Figure 1] as dual graph of certain rational curves on the K3 surface whose transcendental lattice is $\langle 2 \rangle^2$, which is a different way to describe the surface $S_{5,5}$.

Let $\pi : S_{5,5} \to \tilde{R}$ denote the double cover. As can be deduced from (2.4) and the above identifications, pushing forward curve classes has the following effect:

\begin{align*}
\pi_* \Omega_{0_1}^{(1)} &= m_1 & \pi_* \Omega_{3,2}^{(1)} &= 2G_4 & \pi_* \Omega_{3,2}^{(2)} &= E_1 & \pi_* \Omega_{1,2}^{(2)} &= 2G_2 & \pi_* Q_0 &= 2F_1 \\
\pi_* \Omega_{1,0}^{(1)} &= 2G_3 & \pi_* \Omega_{1,0}^{(1)} &= E_4 & \pi_* \Omega_{1,0}^{(2)} &= 2H_1 & \pi_* \Omega_{3}^{(2)} &= E_2 & \pi_* \Omega_{3}^{(2)} &= 2F_4 \\
\pi_* \Omega_{1,0}^{(1)} &= E_3 & \pi_* \Omega_{4,3}^{(1)} &= 2H_4 & \pi_* \Omega_{4,3}^{(2)} &= \ell_2 & \pi_* \Omega_{4,3}^{(2)} &= 2H_2 & \pi_* \Omega_{1}^{(2)} &= 2F_3 \\
\pi_* \Omega_{2,1}^{(1)} &= 2H_3 & \pi_* \Omega_{1}^{(1)} &= m_2 & \pi_* \Omega_{1,0}^{(2)} &= 2E_{T_1} & \pi_* \Omega_{2}^{(2)} &= \ell_1 & \pi_* \Omega_{4}^{(2)} &= 2F_2 \\
\pi_* \Omega_{2,1}^{(1)} &= m_3 & \pi_* \Omega_{4,0}^{(1)} &= 2E_{T_2} & \pi_* \Omega_{2,0}^{(2)} &= \ell_3 & \pi_* \Omega_{4,0}^{(2)} &= 2G_1 & \pi_* \Omega_{2}^{(2)} &= 2E_3.
\end{align*}

4.1.3. Weierstrass equation of $S_{5,5}$. By the Weierstrass equation (2.3) the fibers of $\mathcal{E}_{R_{5,5}}$ of type $I_5$ are the fibers over $\mu = 0$ and $\mu = \infty$. So the base change branched on these fibers is given by $\mu \to \mu^2$ and the elliptic fibration on $S_{5,5}$ induced by the one on $R_{5,5}$ is

\begin{align*}
y^2 &= x^3 + A(\mu)x + B(\mu), \quad \text{where} \\
A(\mu) &= -\frac{1}{48}\mu^8 - \frac{1}{4}\mu^6 - \frac{7}{24}\mu^4 + \frac{1}{4}\mu^2 - \frac{1}{48}, \quad \text{and}
\end{align*}
admits a non-symplectic involution \( \iota \). The set of generators of the Néron–Severi group is given by the class of the fiber of the group and the transcendental lattice of this K3 surface are computed in [3] and a cover \( X \). (see (4.5)).

4.2.1. Geometric description of \( X_{5,5} \) and its Néron–Severi group. The surface \( X_{5,5} \) admits a non-symplectic involution \( \iota \) which is the cover involution of the double cover \( X_{5,5} \to R_{5,5} \) and which fixes two elliptic curves.

The elliptic fibration \( E_{X_{5,5}} : X_{5,5} \to \mathbb{P}^1 \) induced by \( E_{R_{5,5}} : R_{5,5} \to \mathbb{P}^1 \) has four fibers of type \( I_\text{II} \) and four fibers of type \( I_1 \). Moreover it has a 5-torsion section, induced by the one of sections of the elliptic fibration on \( E_{R_{5,5}} \). The Néron–Severi group and the transcendental lattice of this K3 surface are computed in [3] and a set of generators of the Néron–Severi group is given by the class of the fiber of the fibration, the zero section, one section of order 5 and the irreducible components of the reducible fibers of the fibration.

The curves \( \Theta_i^{(j)} \) are not in the branch locus and we denote by \( \Omega_i^{(j,k)} \) for \( k = 1,2 \) the two disjoint rational curves which are mapped to \( \Theta_i^{(j,k)} \) by the quotient map \( X_{5,5} \to R_{5,5} \). The curves \( P_i \) are not in the branch locus and we denote by \( Q_i \) their 2 : 1 cover in \( X_{5,5} \). The dual graph of this configuration is shown in Figure [4]. This diagram is also a tropical surface, similar to the one given in [10] Figure 1], as pointed out by B. Sturmfels.

4.2.2. Weierstrass equation of \( X_{5,5} \). Let us denote by \( \mu_1 \) and \( \mu_2 \) two arbitrary points of \( \mathbb{P}^1 \) such that the fibers of \( \mathbb{P}^1 \) over \( \mu_1 \) and \( \mu_2 \) are smooth. Let \( X_{5,5} \) be the surface obtained from \( R_{5,5} \) by a base change of order 2 branched in \( \mu_1 \) and \( \mu_2 \).

We already observed that the surface \( X_{5,5} \) lives in a 2-dimensional family of K3 surfaces and its equation depends on the two parameters \( \mu_1 \) and \( \mu_2 \).
4.2.3. *fibers.* whose discriminant is (4.4) \[ \mu X \] It induces on branched on the union of the two cubics \( x_0 \) and \( x_2 \) and (4.7) by the equation one of type I surfaces with prescribed reducible fibers, whose singular fibers are:\[ \mu \]

Branch fibers \( \mu \) over \( 1 \) can choose the fiber of type I and theoretically one has four different admissible choices to do that. Indeed one can choose the fiber of type I and similarly one can choose the fiber of type I which is the branch fiber to be the fiber either over \( -11 + 5\sqrt{5} \) or over

\[ \mu = \mu_1 \alpha^2 + \beta^2, \quad \lambda = \alpha^2 + \beta^2/\mu_2. \]

It induces on \( X_{5,5} \) the elliptic fibration

\[ y^2 = x^3 + A(\alpha : \beta)x + B(\alpha : \beta) \]

whose discriminant is

\[ \begin{align*}
(\alpha^2\mu_2 + \beta^2)^5 & (\mu_1 \alpha^2 + \beta^2)^5 (\alpha^4 \mu_1^2 \mu_2^2 + 11\alpha^4 \mu_1 \mu_2 \beta^2 + 11\alpha^2 \mu_1 \mu_2 \beta^2 + 2\alpha^2 \mu_2 \beta^2 + \mu_2^2 \beta^4 + 11\beta^4 \mu_2 - \beta^4)) / (16\mu_2^7) \\
\end{align*} \]

For generic values of \( \mu_1 \) and \( \mu_2 \) the elliptic fibration has \( 4I_5 + 4I_1 \) as singular fibers.

4.2.3. *Double cover of \( \mathbb{P}^2 \).* On the other hand, \( X_{5,5} \) is the double cover of \( \mathbb{P}^2 \) branched on the union of the two cubics \( x_1x_2(x_0 - x_1) + \mu_1x_0(x_0 - x_1 - x_2)(x_0 - x_2) = 0 \) and \( x_1x_2(x_0 - x_1) + \mu_2x_0(x_0 - x_1 - x_2)(x_0 - x_2) = 0. \) So \( X_{5,5} \) can be described by the equation

\[ \begin{align*}
w^2 &= (x_1x_2(x_0 - x_1) + \mu_1x_0(x_0 - x_1 - x_2)(x_0 - x_2)) \\
&\quad \quad \quad (x_1x_2(x_0 - x_1) + \mu_2x_0(x_0 - x_1 - x_2)(x_0 - x_2)). \\
\end{align*} \]

4.3. *Branch fibers \( I_5 \) and \( I_1 \).* If one uses as branch fibers a fiber of type \( I_5 \) and one of type \( I_1 \) one obtains a rigid K3 surface (in the moduli space of the elliptic K3 surfaces with prescribed reducible fibers), whose singular fibers are \( I_{10} + 2I_5 + I_2 + 2I_1 \) and theoretically one has four different admissible choices to do that. Indeed one can choose the fiber of type \( I_5 \) which is the branch fiber to be the fiber either over \( \mu_1 = 0 \) or over \( \mu_1 = \infty \) and similarly one can choose the fiber of type \( I_1 \) which is the branch fiber to be the fiber either over \( \mu_2 = (-11 + 5\sqrt{5})/2 \) or over\

\[ \begin{align*}
\end{align*} \]
\( \mu_2 = (-11 - 5\sqrt{5})/2 \). In order to obtain the Weierstrass equation of these elliptic fibrations it suffices to apply the base change (4.4) with the chosen values for \( \mu_1 \) and \( \mu_2 \).

We assume that \( \mu_2 = (-11+5\sqrt{5})/2 \) and we obtain the following two Weierstrass equations. If \( \mu_1 = 0 \) the base change (4.4) applied to \( \mu_1 = 0 \) and \( \mu_2 = (-11 + 5\sqrt{5})/2 \) gives an elliptic fibration:

\[
y^2 = x^3 + A(\alpha : \beta)x + B(\alpha : \beta)
\]

whose discriminant is

\[-\frac{1}{512} \left( -\alpha^2 + 5\beta^2\sqrt{5} \right) \left( -2\alpha^2 - 11\beta^2 + 5\beta^2\sqrt{5} \right) ^5 \alpha^2\beta^{10}.
\]

In order to choose \( \mu_1 = \infty \), one has to slightly change the equation of the base change (4.4), which now is \( \mu = \alpha^2 \) and \( \lambda = \alpha^2/\mu_2 + \beta^2 \) and one obtains

\[
y^2 = x^3 + A(\alpha : \beta)x + B(\alpha : \beta)
\]

whose discriminant is

\[\frac{1}{5120} \left( -375125 + 167761\sqrt{5} \right) \left( -25\alpha^2 + \beta^2\sqrt{5} \right) \left( -2\alpha^2 + 11\beta^2 + 5\beta^2\sqrt{5} \right) ^5 \beta^2\alpha^{10}.
\]

We observe that in the first case the K3 surface obtained is described as a double cover of \( \mathbb{P}^2 \) by the equation

\[w^2 = x_1x_2(x_0-x_1) \left( x_0x_1x_2(13 + 5\sqrt{5}) - x_1^2x_2(11 + 5\sqrt{5}) + 2x_0^3 - 4x_0^2x_2 - 2x_1x_0^2 + 2x_0x_2^2 \right),
\]

in the second by the equation

\[w^2 = x_0(x_0-x_1-x_2)(x_0-x_2) \left( x_0x_1x_2(13 + 5\sqrt{5}) - x_1^2x_2(11 + 5\sqrt{5}) + 2x_0^3 - 4x_0^2x_2 - 2x_1x_0^2 + 2x_0x_2^2 \right).
\]

4.4. Branch fibers \( I_5 \) and \( I_0 \). If one chooses as branch fibers one fiber of type \( I_5 \) and one of type \( I_0 \) one obtains a 1-dimensional family of K3 surfaces, whose singular fibers are \( I_{10} + 2I_5 + 4I_1 \) and theoretically one has two different admissible ways to do that. Indeed one can choose that the fiber of type \( I_5 \) which is the branch fiber is the fiber either over \( \mu_1 = 0 \) or over \( \mu_1 = \infty \), while \( \mu_2 \) is the parameter of the family. In order to obtain the equations of these elliptic fibrations one has to apply the base changes \((\mu = \beta^2, \lambda = \alpha^2 + \beta^2/\mu_2) \) or \((\mu = \alpha^2, \lambda = \alpha^2/\mu_2 + \beta^2) \) to the equation (2.3), exactly as in the previous sections.

Similarly one can describe these K3 surfaces as a double cover of \( \mathbb{P}^2 \) substituting in (4.7) the appropriate values of \( \mu_1 \) and \( \mu_2 \).

4.5. Branch fibers \( I_1 \) and \( I_0 \). If one chooses as branch fibers one fiber of type \( I_1 \) and one of type \( I_0 \) one obtains a 1-dimensional family of K3 surfaces, whose singular fibers are \( 4I_5 + I_2 + 2I_1 \) and theoretically one has two different admissible ways to do that. Indeed one can choose that the fiber of type \( I_1 \) which is the branch fiber is the fiber either over \( \mu_1 = (-11 - 5\sqrt{5})/2 \) or over \( \mu_1 = (-11 + 5\sqrt{5})/2 \), while \( \mu_2 \) is the parameter of the family. In order to obtain the equations of these elliptic fibrations one has to apply the base change (4.4) with the chosen \( \mu_1 \) to the equation (2.3) and to obtain an equation of this surface as a double cover of \( \mathbb{P}^2 \) one has to substitute the chosen \( \mu_1 \) in (4.7).
4.6. Branch fibers $2I_1$. If one chooses as branch fibers the two fibers of type $I_1$ one obtains a rigid K3 surface, whose reducible fibers are $4I_5 + 2I_2$. In order to obtain the equation of this elliptic fibration one has to apply the base change (4.4) with the chosen $\mu_1 = (-11 - 5\sqrt{5})/2$ and $\mu_2 = (-11 + 5\sqrt{5})/2$ to the equation (2.3). Similarly to obtain an equation of this surface as a double cover of $\mathbb{P}^2$ one has to substitute $\mu_1 = (-11 - 5\sqrt{5})/2$ and $\mu_2 = (-11 + 5\sqrt{5})/2$ in (4.7).

5. Elliptic fibrations on K3 surfaces induced by the conic bundles

The aim of this section is to describe both geometrically and by the Weierstrass equations the elliptic fibrations induced by the conic bundles $B_i$ (described in Section 3) on the K3 surfaces described in Section 4. We also provided a general method to find these Weierstrass equations, under some assumption on the conic bundles, see Section 5.2.

5.1. An example. Let us consider the K3 surface $S_{5,5}$, whose equation as a double cover of $\mathbb{P}^2$ is given by (4.3). Let us consider also the conic bundle $|B_1|$ from Section 3. By [11, Theorem 5.3], the conic bundle $|B_1|$ induces an elliptic fibration on $S_{5,5}$ with three reducible fibers of type $I^*_2$: one whose components are $Q_0$, $\Omega^{(1)}_{1,0}$, $\Omega^{(1)}_0$, $\Omega^{(1)}_1$, $Q_1$, and $\Omega^{(1)}_{2,1}$, one whose components are $Q_2$, $\Omega^{(2)}_{4,0}$, $\Omega^{(2)}_4$, $\Omega^{(2)}_{4,3}$, $\Omega^{(2)}_3$, $Q_4$, and $\Omega^{(2)}_{3,2}$, and one whose components are $\Omega^{(1)}_{4,3}$, $\Omega^{(1)}_{3,2}$, $\Omega^{(1)}_3$, $Q_3$, $\Omega^{(2)}_1$, $\Omega^{(2)}_{2,1}$, and $\Omega^{(2)}_{1,0}$.

5.1.1. Equation of the elliptic fibration on $S_{5,5}$ induced by $|B_1|$. Let us consider the conic bundle $B_1$ on $R_{5,5}$ associated to the pencil of lines $x_1 = \tau x_0 \subset \mathbb{P}^2$. It induces an elliptic fibration on $S_{5,5}$. To find the equation of this elliptic fibration we use the equation of $S_{5,5}$ as double cover of $\mathbb{P}^2$, i.e. the equation (4.3) and we substitute in $x_1 = \tau x_0$ in (4.3).

This gives:

$$w^2 = (\tau x_0)x_2(x_0 - \tau x_0)x_0(x_0 - \tau x_0 - x_2)(x_0 - x_2).$$

We put $x_2 = 1$ and we obtain

$$w^2 = \tau(1 - \tau)x_0^3(x_0 - \tau x_0 - 1)(x_0 - 1).$$

Let us consider the change of coordinates $w \mapsto wx_0$ and divide both the members by $x_0^3$. We obtain

$$w^2 = \tau(1 - \tau)x_0(x_0 - \tau x_0 - 1)(x_0 - 1).$$

This is the equation of an elliptic fibration over $\mathbb{P}^1_\tau$. Moreover one can explicitly compute the Weierstrass form: first one uses the change of coordinates $w \mapsto \tau^2(1 - \tau)w$ and $x_0 \mapsto \tau x_0$ obtaining

$$w^2\tau^4(1 - \tau)^2 = \tau^2(1 - \tau)x_0(\tau x_0(1 - \tau) - 1)(\tau x_0 - x_2)$$

and so

$$w^2 = x_0\left(x_0 - \frac{1}{\tau(1 - \tau)}\right)\left(x_0 - \frac{1}{\tau}\right)$$

Second, one considers the change of coordinates $w \mapsto w/\tau^3(1 - \tau)^3$ and $x_0 \mapsto x_0/\tau^2(1 - \tau)^2$ and multiplies all the equation by $\tau^6(1 - \tau)^6$. So one obtains

$$(5.1)\quad w^2 = x_0(x_0 - \tau(1 - \tau))(x_0 - \tau(1 - \tau)^2).$$

The discriminant is $\tau^8(1 - \tau)^8$ and so, by Tate’s algorithm, there are three fibers of type $I^*_2$ over $\tau = 0$, $\tau = 1$, $\tau = \infty$. 

5.2. An algorithm to compute Weierstrass equations. The aim of this section is to formalize systematically what we did above.

**Setup.** Let \( V \) be a K3 surface obtained by a base change of order 2 from a rational elliptic surface \( R \). Therefore, \( V \) can be described as double cover of \( \mathbb{P}^2 \) branched on the union of two (possibly reducible) plane cubics from the pencil determining \( R \). It has an equation of the form

\[
(5.2) \quad w^2 = f_3(x_0 : x_1 : x_2)g_3(x_0 : x_1 : x_2).
\]

Let \( B \) be a conic bundle on \( R \), e.g. a basepoint-free linear system of rational curves giving \( R \to \mathbb{P}^1_\tau \). Pushing forward to \( \mathbb{P}^2 \), \( B \) is given by a pencil of plane rational curves with equation \( h(x_0 : x_1 : x_2, \tau) \). The polynomial \( h(x_0 : x_1 : x_2, \tau) \) is homogeneous in \( x_0, x_1, x_2 \), say of degree \( e \geq 1 \) and linear in \( \tau \).

As the anticanonical series on \( R \) coincides with the elliptic fibration, the adjunction formula implies that every curve with equation \( h(x_0 : x_1 : x_2, \tau) \) meets both of the branch curves (the proper transforms on \( R \) of) \( f_3 = 0 \) and \( g_3 = 0 \) in two additional points. It therefore meets (the proper transform of) their union \( f_3g_3 = 0 \) in four points. (Note that there may be additional points of intersection on \( \mathbb{P}^2 \) which are separated in the blow-up \( R \)). Therefore the preimage in \( V \) is the double cover of a rational curve branched over 4 points, e.g. the standard presentation of an elliptic curve. For general \( \tau \), we must find an isomorphism of the curve \( h(x_0 : x_1 : x_2, \tau) = 0 \) with \( \mathbb{P}^1 \), and extract the images of the four intersection points with \( f_3g_3 = 0 \).

When \( e \leq 3 \), an isomorphism with \( \mathbb{P}^1 \) is provided by projection from a point of order \( e-1 \) on the curve (e.g. any point in \( \mathbb{P}^2 \) if \( e = 1 \), a point on the conic if \( e = 2 \), and a double point of the cubic if \( e = 3 \)). Such a point necessarily exists (in the case \( e = 3 \) the singularity must be a basepoint of the pencil) and is also necessarily a basepoint of the original pencil of cubics giving \( \mathcal{E}_R \). Up to acting by \( \text{PGL}_3(\mathbb{C}) \), we may assume that this point is \((0 : 1 : 0)\).

**Algorithm when** \( e \leq 3 \).

1. Compute the resultant of the polynomials \( f_3(x_0 : x_1 : x_2)g_3(x_0 : x_1 : x_2) \) and \( h(x_0 : x_1 : x_2, \tau) \) with respect to the variable \( x_1 \). The result is a polynomial \( r(x_0 : x_2, \tau) \) which is homogeneous in \( x_0 \) and \( x_2 \), corresponding to the images of all of the intersection points \( \{f_3g_3 = 0\} \cap \{h_\tau = 0\} \) after projection from \((0 : 1 : 0)\).

2. Since \( B \) is a conic bundle, \( r(x_0 : x_2, \tau) \) will be of the form \( a(x_0 : x_2, \tau)^2b(x_0 : \) \( x_2, \tau)c(\tau) \), where \( a \) and \( b \) are homogeneous in \( x_0 \) and \( x_2 \), the degree of \( a \) depends upon \( e \) and the degree of \( b \) in \( x_0 \) and \( x_2 \) is 4.

3. The equation of \( V \) is now given by \( w^2 = r(x_0 : x_2, \tau) \), which is birationally equivalent to

\[
(5.3) \quad w^2 = c(\tau)b(x_0 : x_2, \tau),
\]

by the change of coordinates \( w \mapsto wa(x_0 : x_2, \tau) \). Since for almost every \( \tau \), the equation \((5.3)\) is the equation of a 2 : 1 cover of \( \mathbb{P}^1(x_0 : x_2) \) branched in 4 points, \((5.3)\) is the equation of the genus 1 fibration on the K3 surface \( V \) induced by the conic bundle \( B \).

4. If there is a section of fibration \((5.3)\), then it is possible to obtain the Weierstrass form by standard transformations.
Remark 5.1. The algorithm can be applied exactly in the same way to the generalized conic bundles, and not only to the conic bundles.

When \( e \geq 4 \), projection from a point may suffice, for example if all curves have a basepoint of degree \( e - 1 \). However there are several conic bundles whose general member cannot be parametrized by lines.

We now consider a parametrization which can be done by conics. Let \( \mathcal{P} \) be a pencil of rational curves of degree \( e \) passing through the (possibly infinitely near) basepoints \( T_1, \ldots, T_r \) with certain multiplicities. Let \( \mathcal{C} \) be a pencil of conics whose basepoints are among \( T_1, \ldots, T_r \) and such that \( 2e - 1 \) intersection points between a generic curve in \( \mathcal{P} \) and a generic curve in \( \mathcal{C} \) are in \( \{T_1, \ldots, T_r\} \). So there is exactly one extra intersection between a generic curve in \( \mathcal{P} \) and a generic curve in \( \mathcal{C} \). This allows to parametrize the curves in \( \mathcal{P} \) by the curves in \( \mathcal{C} \). If moreover the base points of \( \mathcal{C} \) are three distinct points and one infinitely near point we will say that the condition \((\ast)\) is satisfied. So \((\ast)\) is satisfied if the curves in \( \mathcal{P} \) can be parametrized by a pencil of conics passing through 4 points, exactly two of which are infinitely near.

If the condition \((\ast)\) is satisfied, up to changing coordinates by some matrix \( M \in \text{PGL}_3(\mathbb{C}) \), we may assume that the basepoints of \( \mathcal{C} \) are \( p_1 = (0 : 0 : 1), p_2 = (0 : 1 : 0), p_3 = (1 : 0 : 0) \) and the infinitely near point \( p'_1 \) corresponds to the line \( x_0 = x_1 \). The pencil of degree 2 maps \( \mathbb{P}^1 \rightarrow \mathbb{P}^2 \) sending

\[
1 \mapsto p_1, \quad \infty \mapsto p_2, \quad 0 \mapsto p_3
\]

with derivative at \( z = 1 \) in the direction of the line \( x_0 = x_1 \) is given by

\[
(x_0 : x_1 : x_2) = (z - 1 : z(z - 1) : p \cdot z), \quad p \in \mathbb{P}^1.
\]

In the following we are interested in pencils of quartics which satisfy the condition \((\ast)\), so we study the effect of this condition on quartic curves. We say that a pencil of quartics satisfies \((\dagger)\) if, up to a change of coordinates, it is of one of the following types: (1) each quartic is double at \( p_2 \) and has a tacnode at \( p_1 \) with principal tangent specified by \( p'_1 \); (2) each quartic is double at \( p_2 \) and \( p_3 \) and has a cusp at \( p_1 \) with principal tangent specified by \( p'_1 \).

We recall that, by the construction of the conic bundles, all the basepoints of \( \mathcal{P} \) (and thus also of \( \mathcal{C} \)) are also singular points for the sextic \( f_3 \cdot g_3 = 0 \).

Algorithm assuming \((\dagger)\).

1. Factor \( h(z - 1 : z(z - 1) : p_2 ; \tau) = c(\tau)z^a(z - 1)^b r(z, p, \tau) \) where \( r(z, p, \tau) \) is linear in \( z \) and \( a + b = 5 \) or 6 depending on the multiplicity of \( h \) at \( p_2 \). The solution \( z_0 \) of \( r(z, p, \tau) = 0 \) gives the rational parameterization \( h(z_0 - 1 : z_0(z_0 - 1) : p_2 z_0, \tau) = 0 \) with parameter \( p \in \mathbb{P}^1 \).
2. A birational equation of the K3 surface is given by

\[
w^2 = (f_3 \cdot g_3)(z_0 - 1 : z_0(z_0 - 1) : p_2 z_0).
\]
3. If there is a section of fibration \((\dagger),(3)\), then it is possible to obtain the Weierstrass form by standard transformations.

This algorithm can be generalized to pencil of curves satisfying \((\ast)\).

5.3. The elliptic fibrations induced by conic bundles. Here we can describe and compute the equations of all the elliptic fibrations induced by the conic bundles on the different K3 surfaces introduced. For this purpose, we apply the algorithm, described in the previous section, to the equations of the conic bundles given in Section 3 and to the Weierstrass equations given in Section 4.
5.3.1. The K3 surface $S_{5,5}$. The conic bundle $|B_2|$ induces an elliptic fibration on $S_{5,5}$ with two reducible fibers of type $I^*_1$: one whose components are $Q_0$, $\Omega^{(1)}_{0,4}$, $\Omega^{(1)}_{0,1}$, $\Omega^{(1)}_{1,0}$, $\Omega^{(1)}_2$, $Q_2$, and $\Omega^{(1)}_{2,1,1}$, and one whose components are $Q_3$, $\Omega^{(2)}_{1,0}$, $\Omega^{(2)}_1$, $\Omega^{(2)}_{1,0}$, $\Omega^{(2)}_4$, $\Omega^{(2)}_{3,3,2}$, $Q_4$, and $\Omega^{(2)}_{3,3,2}$.

The Weierstrass equation is computed applying the algorithm to $f_{3g_3} = x_0x_1x_2(x_0-x_1)(x_0-x_2)(x_0-x_1-x_2)$, by (5.3), and $h(x_0 : x_1 : x_2, \tau) = x_1x_2 - \tau(x_0x_2 - x_0^2)$.

One obtains the Weierstrass equation
\[
y^2 = x^3 - \frac{\tau^2(-\tau^2 + \nu^4 + 1)}{3} x - \frac{(1/27)^3(-2 + \nu^2)(-1 + 2\nu^2)(\nu^2 + 1)}{27}.
\]

So the discriminant $\Delta(\nu) = -\tau^{10}(-1 + \nu)^2(\nu + 1)^2$. Hence, by Tate’s algorithm, this fibration has two fibers of type $I^*_1$ over $\tau = 0$, $\infty$ and two fibers of type $I_2$ over $\tau = \pm 1$.

The conic bundle $|B_3|$ induces an elliptic fibration on $S_{5,5}$ with two reducible fibers: one of type $I^*_2$ whose components are $Q_0$, $\Omega^{(1)}_{0,4}$, $\Omega^{(1)}_4$, $\Omega^{(1)}_{0,1}$, $\Omega^{(1)}_2$, $\Omega^{(1)}_{3,3,2}$, $\Omega^{(1)}_3$, $Q_3$, and $\Omega^{(1)}_{3,3,2}$, one of type $III^*$ whose components are $Q_4$, $\Omega^{(2)}_3$, $\Omega^{(2)}_4$, $\Omega^{(2)}_{3,3,2}$, $\Omega^{(2)}_4$, and $\Omega^{(2)}_{3,3,2}$.

The Weierstrass equation is
\[
y^2 = x^3 - \frac{\tau^3(\tau^3 + 6\tau^2 + 9\tau + 3)}{3} x - \frac{\tau^5(\tau + 3)(2\tau^4 + 12\tau^2 + 18\tau + 9)}{27}.
\]

So the discriminant $\Delta(\nu) = -\tau^9(\nu + 4)(\nu + 1)^2$. Hence, by Tate’s algorithm, this fibration has one fiber of type $I^*_2$ over $\nu = \infty$, one fiber of type $III^*$ over $\nu = 0$, one fiber of type $I_2$ over $\nu = -1$ and one fiber of type $I_1$ over $\nu = -4$.

5.3.2. The K3 surface $X_{5,5}$. Here we consider the elliptic fibrations induced by $B_1$ on $X_{5,5}$. We recall that in this case one has to apply the algorithm to (5.3).

We summarize the results in the following table, where $r$ denotes the rank of the Mordell-Weil group of the fibration.

| $B_1$ | $\Delta$ | $\text{singular fibers}$ | $r$ |
|-------|----------|--------------------------|-----|
| $I^*_1$ | $-\tau^8(\tau - 1)(\mu_1 - \mu_2)^4$ | $\nu^2(\nu^2 + \nu^4 + 1)$ | $2$ |
| $2I_1$ | $\tau = 0$ |
| $2I_5$ | $\nu = \infty$, $1$ |
| $6I_1$ | $\nu = 0$, $\infty$ |

| $B_2$ | $-\tau^8(\tau - 1)^4(\mu_1 - \mu_2)^4$ | $\nu^2(\nu^2 + \nu^4 + 1)$ | $2$ |
|-------|----------|--------------------------|-----|
| $2I_4$ | $\tau = 0$, $\infty$ |
| $8I_1$ | $\nu = 0$, $\infty$ |

| $B_3$ | $-\tau^8(\tau + 2\tau^2 + \nu^2 - 2\nu^2 - 4\mu_2^2 + 2\mu_2 - \nu + \mu_2)^4$ | $\nu^2(\nu^2 + \nu^4 + 1)$ | $1$ |
|-------|----------|--------------------------|-----|
| $I^*_2$ | $\tau = 0$ |
| $I^*_1$ | $\nu = \infty$ |
| $6I_1$ | $\nu = 0$, $\infty$ |

5.3.3. Other K3 surfaces. As we saw above, all the equations for K3 surfaces that are double covers of $R_{5,5}$ branched over some special fibers can be obtained from the general equation for $X_{5,5}$ by substituting particular values of $\mu_1$ and $\mu_2$. In particular in order to find the Weierstrass equations of the elliptic fibrations induced by the conic bundles $B_i$ on a specific K3 surface it suffices to substitute in the appropriate values of $\mu_1$ and $\mu_2$. As an example here we construct a table analogous to (5.5) if the K3 surface is obtained by $R_{5,5}$ branching along one fiber of type $I_5$ and one smooth fiber. We already noticed that one has two different choices
for the $I_5$ branch fiber. Once one chooses the branch fiber $I_5$, the construction is not symmetric in $I_5$. For $i = 1, 2$ the reducible fibers of the conic bundle $|B_i|$ are symmetric up to switching the $I_5$-fibers, so the conic bundle $|B_i|$ is associated to elliptic fibrations with the same property choosing differently the $I_5$ branch fiber. For the conic bundles $|B_1|$ and $|B_2|$ we will choose the $I_5$ branch fiber to be the one over $\mu_1 = 0$. The conic bundle $|B_3|$ has a unique reducible fiber, supported over one specific $I_5$, so the elliptic fibrations induced by this conic bundle have not necessarily the same properties if one change the $I_5$ branch fibers. So we give the equations of the elliptic fibrations if one chose both $\mu_1 = 0$ and $\mu_1 = \infty$.

For all the conic bundles $\mu_2$ is the parameter of the $1$-dimensional family of K3 surfaces we are considering. So we obtain the following (where $r = \text{rank}(\text{MW})$ and both the reducible fibers and $r$ are given for generic choice of $\mu_2$):

(5.7)

| $\Delta$ | $\text{singular fibers}$ | $r$ |
|---------|-----------------|-----|
| $B_1$   | $-\tau^7\mu_2^2(-1+\tau)^8(\tau^3-2\tau^2-2\tau^2\mu_2+\tau+6\tau\mu_2+\tau\mu_2^2-4\mu_2^2)$ | $I_1^0$ | $\tau = 0$, $I_2^0$ | $\tau = 1$ | $1$ |
|         | $I_6$ | $\tau = \infty$, $3I_1$ |       |       |       |
| $B_2$   | $-\tau^{10}\mu_2^2(-1+\tau)^2(\mu_2+\tau^2\mu_2+2\mu_2-\tau^3-\tau+2\tau^2)(\mu_2-\tau)$ | $I_1^0$ | $\tau = 0$, $I_2^0$ | $\tau = 1$ | $1$ |
|         | $I_6$, $\tau = \infty$, $4I_1$ |       |       |       |       |
| $B_3$,  | $-\mu_2^2\tau\tau(\tau+1)^2(\tau+2\tau^2+\tau^3-6\mu_2\tau-2\mu_2\tau^2+4\mu_2^2+\tau\mu_2^2)$ | $II_2^0$ | $\tau = \infty$, $I_2^0$ | $\tau = -1$ | $1$ |
| $\mu_1 = 0$ | $I_{10}$ | $\tau = 0$, $3I_1$ |       |       |       |
| $B_3$,  | $-\tau^8(4+\tau)(\tau+2\tau^2+\tau^3-6\mu_2\tau-2\mu_2\tau^2+4\mu_2^2+\tau\mu_2^2)$ | $I_2^0$ | $\tau = 0$ | $4I_1$ | $1$ |
| $\mu_1 = \infty$ | $I_2$ | $\tau = \infty$, $4I_1$ |       |       |       |

6. The K3 surface $S_{5,5}$ and its elliptic fibrations

The aim of this section is to prove the following results, computing the equations of all the elliptic fibrations on $S_{5,5}$.

**Proposition 6.1.** The K3 surface $S_{5,5}$ admits 13 different elliptic fibrations. One of them is induced by $\mathcal{E}_R$, 3 are induced by conic bundles, 3 by splitting genus one pencils and 6 by generalized conic bundles. The equations of these elliptic fibrations are given in [4.2] (the one induced by $\mathcal{E}_R$), in [5.4], [5.7] [5.9] (the ones induced by the conic bundles), in [6.4] (the ones induced by splitting genus 1 pencil) and in [6.8] [6.9] (the ones induced by generalized conic bundles).

To prove this, we deeply analyze the elliptic fibrations on $S_{5,5}$ induced by splitting genus 1 pencils and generalized conic bundles, in particular giving an algorithm to find the Weierstrass equation of any elliptic fibration induced by a splitting genus 1 pencil.

The K3 surface $S_{5,5}$ can be also described as the (unique!) K3 surface which admits a non-symplectic involution fixing 10 rational curves. Indeed, by our construction it is clear that $\iota$ fixes 10 rational curves (the inverse image of the components of the two $I_5$ fibers). The fact that this K3 surface is unique is classically known, and due to Nikulin, see [8]. The transcendental lattice of this K3 surface is $T_S \simeq (2) \oplus (2)$. The elliptic fibrations on this K3 surface are classified by Nishiyama, see [9] Table 1.2, who used a lattice theoretic method that we will apply later to a different K3 surface, in Section [4] The complete list of the elliptic fibrations is the
the following:

| n° | singular fibers | MW          |
|----|----------------|-------------|
| 1  | $2II^{*} + 2I_1$ | $\{1\}$    |
| 2  | $II^{*} + I_6^* + 2I_1$ | $\{1\}$    |
| 3  | $I^*_{12} + 2I_2 + 2I_1$ | $\mathbb{Z}/2\mathbb{Z}$ |
| 4  | $2III^* + I_6^*$ | $\mathbb{Z}/2\mathbb{Z}$ |
| 5  | $III^* + I_6^* + I_2 + I_1$ | $\mathbb{Z}/2\mathbb{Z}$ |
| 6  | $I_{18} + I_2 + 4I_1$ | $\mathbb{Z}/3\mathbb{Z}$ |

Since the involution $\iota$ acts as the identity on the Néron–Severi group of $S_{5,5}$, there are no fibrations of type 3 on this K3 surface.

The fibration 13 in Table (6.1) is the one induced by the fibration $E_{R_{5,5}}$ and it has equation (6.2). By Section 5, the fibrations 5, 9, and 12 are induced by conic bundles and their equations are (5.5), (5.4), and (5.1), respectively.

The other fibrations are induced either by generalized conic bundles or by splitting genus 1 pencils.

An elliptic fibration induced by a splitting genus 1 pencil corresponds to a fibration of genus 1 curves on a non-relatively minimal rational elliptic surface (that is, this fibration admits $(-1)$-curves as components of some fibers). The original relatively minimal rational elliptic surface $R_{5,5}$ can be recovered from this non-minimal surface by blowing down some divisors. A different choice of divisors to blow-down, namely the $(-1)$–curves which are components of the fibers of the splitting genus 1 pencil, gives us another rational elliptic surface on which the splitting genus 1 pencil above corresponds to a relatively minimal elliptic fibration. Hence each fibration given by a splitting genus 1 pencil is indeed induced by a rational elliptic surface (different from $R_{5,5}$) by a base change of order 2 whose branch locus consists of 10 curves. Considering the list of elliptic fibrations on $S_{5,5}$ given in Table 6.1, one observes immediately that the fibrations 6, 10 and 11 could be of this type, i.e., they could be induced by splitting genus 1 pencils, (this is in fact proved in [4]). Indeed they present some fibers which appear in pairs (each pair is good candidate to be the inverse image of a unique fiber on the rational elliptic surface) and at most two other fibers, which do not appear an even number of time, but which are either of type $I_{2n}$ or of type $IV^*$. These fibers are the one obtained by base change of order 2 branched over $I_n$ or $IV$-fibers, so they could be the ramification fibers of the base change. The others fibration in Table 6.1 have not the same properties, thus can not be induced by rational elliptic surface by a base change of order 2. We already observed that the fibration 13 is induced by the elliptic fibration on $R_{5,5}$ and that the fibrations 5, 9 and 12 are induced by conic bundles, so the fibrations 1, 2, 3, 4, 7, 8 are induced by generalized conic bundles.

6.1. Splitting genus 1 fibrations.

6.1.1. An example, the fibration 6. We give an example of splitting genus 1 pencil of curves: we are looking for a fiber of type $I_{18}$ and it is given by

$$W_X := Q_0 + Q_0^{(2)} + Q_0^{(3)} + Q_4 + Q_4^{(2)} + Q_4^{(3)} + Q_4^{(4)} + Q_{3,2} + Q_2 + Q_{2,1} + Q_1 + Q_1^{(1)} + Q_{1,0} + Q_0^{(1)}.$$
Using (4.1), the class $W_R := \pi_*W_X$ is
\begin{equation}
2F_1 + E_1 + 2G_1 + \ell_1 + 2H_2 + E_2 + 2G_2 + \ell_2 + 2F_4 + E_4 + 2G_4 + m_3 + 2H_3 + E_3 + 2G_3 + m_1 = 5\ell - 2F_1 - 2G_1 - 4H_1 - E_2 - 2F_2 - G_2 - H_2 - 2E_3 - 4F_3 - 2G_3 - 2H_3 - E_4 - F_4 - G_4 - 2H_4 - 2E_{Q_R} - E_{T_2}.
\end{equation}

Since we know that the curves described split in the double cover, we can assume that the class $W_R$ is both the push down and the geometric image of a fiber of our fibration (i.e. $\pi_*W_X = \pi(W_X) = W_R$).

This class is the strict transform on $\tilde{R}$ of quintics in $\mathbb{P}^2$ with the following properties: they have a tacnode in $Q_1$ with principal tangent $\ell_2$; they have a tacnode in $Q_3$ with principal tangent $\ell_3$; they have a node in $Q_5$; the tangent in $Q_2$ is $m_2$; the tangent in $Q_4$ is $m_2$; they pass through $T_2$.

This gives the following families of quintics
\begin{equation}
-bx_0^5 + bx_0^4x_1 + bx_0^4x_2 - ex_0^3x_1x_2 + ex_0^2x_1x_2^2 + ex_0x_1x_2^3 + (-3b - e)x_0x_1^2x_2 + bx_1x_2^2 + bx_1^2x_2^3 = 0.
\end{equation}

This is the equation of the splitting genus 1 pencil that we are looking for. It indeed corresponds to a pencil of curves of genus 1 parametrized by $(b : e)$.

We now have to intersect the branch sextic given in equation (4.3) with (6.3). The resultant of the polynomials (4.3) and (6.3) with respect to the variable $x_0$ is
\begin{equation}
-x_1^{12}x_2^{12}b^3(x_1 - x_2)^4(x_2 + x_1)^2(e + 2b).
\end{equation}

We observe that all the solutions in $(x_1, x_2)$ have even multiplicities, as is necessarily if the double cover splits into two curves, isomorphic to the base curve, see [4 Section 3]. More precisely, the curve splits after the base change of order two branched in $(b : e) = (0 : 1)$ and $(b : e) = (1 : -2)$, cf. Lemma 5.2 below. In order to write down explicitly the Weierstrass form of the elliptic fibration on $X_{5,5}$ one first finds the rational elliptic fibration given by the splitting pencil of genus 1 curves (6.3), and then one performs the base change of order two. This can be computed by any computer algebra system and it is
\begin{equation}
y^2 = x^3 + A(b : e)x + B(b : e),
\end{equation}
where
\begin{equation}
A(b : e) := \frac{23}{48}b^4 - \frac{5}{12}b^3e - \frac{1}{8}b^2e^2 + \frac{1}{12}be^3 - \frac{1}{48}e^4
\end{equation}
and
\begin{equation}
B(b : e) := -\frac{181}{864}b^6 - \frac{17}{144}b^5e + \frac{31}{288}b^4e^2 - \frac{1}{54}b^3e^3 - \frac{5}{288}b^2e^4 + \frac{1}{144}be^5 - \frac{1}{864}e^6.
\end{equation}

The discriminant of this rational elliptic fibration is
\begin{equation}
\frac{1}{16}b^6(e + 2b)(e^2 - 5be + 13b^2)
\end{equation}
and the fibration has one fiber of type $I_9$ and three other singular fibers, all of type $I_1$.

Now we consider the base change of order 2 branched in $(b : e) = (0 : 1)$ and $(b : e) = (1 : -2)$. It can be directly written as a map $\mathbb{P}^1_{(b : e)} \to \mathbb{P}^1_{(b : e)}$, where $b = \beta^2$ and $e = -\beta^2 + 2\beta e + e^2$.

So we obtain a new elliptic fibration on $S_{5,5}$ whose equation is
\begin{equation}
y^2 = x^3 + A'(\beta : e)x + B'(\beta : e),
\end{equation}
where
\begin{equation}
A'(\beta : e) := \frac{23}{48}\beta^4 - \frac{5}{12}\beta^3e - \frac{1}{8}\beta^2e^2 + \frac{1}{12}\beta e^3 - \frac{1}{48}e^4
\end{equation}
and
\begin{equation}
B'(\beta : e) := -\frac{181}{864}\beta^6 - \frac{17}{144}\beta^5e + \frac{31}{288}\beta^4e^2 - \frac{1}{54}\beta^3e^3 - \frac{5}{288}\beta^2e^4 + \frac{1}{144}\beta e^5 - \frac{1}{864}e^6.
\end{equation}
Lemma 6.2. We have the following.

\[ A'(\beta : \epsilon) := \frac{23}{48}\beta^8 - \frac{5}{12}\beta^6(-\beta^2 + 2\beta\epsilon + \epsilon^2) - \frac{1}{8}\beta^4(-\beta^2 + 2\beta\epsilon + \epsilon^2)^2 + \]
\[ + \frac{1}{12}\beta^2(-\beta^2 + 2\beta\epsilon + \epsilon^2)^3 - (1/48)(-\beta^2 + 2\beta\epsilon + \epsilon^2)^4 \]

and

\[ B'(\beta : \epsilon) := -(1/108)\beta^{12} - (5/9)\beta^{11}\epsilon - (7/18)\beta^{10}\epsilon^2 + (28/27)\beta^9\epsilon^3 + (7/12)\beta^8\epsilon^4 - (11/12)\beta^7\epsilon^5 + \]
\[ - (35/72)\beta^6\epsilon^6 + (1/3)\beta^5\epsilon^7 + (5/24)\beta^4\epsilon^8 - (5/108)\beta^3\epsilon^9 - (1/18)\beta^2\epsilon^{10} - (1/72)\epsilon^{11}\beta - (1/864)\epsilon^{12}. \]

The discriminant is
\[ (1/16)\beta^{18}(19\beta^4 - 14\beta^3\epsilon - 3\beta^2\epsilon^2 + 4\beta\epsilon^3 + \epsilon^4)(\epsilon + \beta)^2. \]

This fibration has a fiber of type $I_{18}$, as expected, one fiber of type $I_2$ (in $(\beta : \epsilon) = (1 : -1)$), and four fibers of type $I_1$. By construction this elliptic fibration exhibits $S_{5,3}$ as the double cover of a rational elliptic surface with one fiber of type $I_0$ and three fibers of type $I_1$.

6.1.2. Splitting genus 1 fibration: an algorithm. The aim of this section is to generalize the previous construction to other splitting genus 1 pencils.

**Setup.** Let $\pi : V \to \mathbb{P}^1$ be a K3 surface which is a double cover of a (not necessarily minimal) rational elliptic surface $R$ branched over two fibers. If $\mathcal{H} : R \to \mathbb{P}^1_{(\beta:e)}$ is a splitting genus 1 pencil, then the induced elliptic fibration on $V$ comes via pullback from a double cover $\mathbb{P}^1_{(\beta,e)} \to \mathbb{P}^1_{(b:e)}$. Hence given an equation for the fibration $\mathcal{H}$, it suffices to find the branch points of the map $\mathbb{P}^1_{(\beta:e)} \to \mathbb{P}^1_{(b:e)}$ in order to find the Weierstrass equation for the elliptic fibration on $V$. We now explain how to do this in general, when the branch curves and equations for $\mathcal{H}$ are given in $\mathbb{P}^2$.

Assume that the equation of $V$ as double cover of $\mathbb{P}^2$ is given by $w^2 = f_3(x_0 : x_1 : x_2)g_3(x_0 : x_1 : x_2)$. Let $h((x_0 : x_1 : x_2), (b : e))$ be the equation of the pushforward of a splitting genus 1 pencil from $R$ to $\mathbb{P}^2$. The equation $h$ is homogeneous of some degree in the coordinate $(x_0 : x_1 : x_2)$ on $\mathbb{P}^2$ and linear in the coordinate $(b : e)$ of the base $\mathbb{P}^1$ of the pencil. For every $(b : e)$, the curve with equation $h((x_0 : x_1 : x_2), (b : e))$ is of arithmetic genus 1.

Write $\bigcup_{k \in K} C_k$ for the irreducible components of the branch curves $f_3g_3 = 0$. For $D \subset \mathbb{P}^2$, write $\mult_{C_k}(D)$ for the multiplicity of the component $C_k$ in $D$. Then we have the following.

**Lemma 6.2.** A plane curve $D_{(b:e)} \subset \mathbb{P}^2$ that is member of the pencil $\mathcal{H}$ is a branch curve for the double cover $V \rightarrow \tilde{R}$ induced by the splitting genus 1 pencil if and only if there exists $k \in K$ such that $\mult_{C_k}(D_{(b:e)}) \neq 0$.

**Proof.** If $D$ meets the branch curves transversely, it does so only in points of even multiplicity, and so splits in the double cover as two disjoint elliptic curves. It suffices, therefore, to show that if $D$ contains at least one component $C_k$, the support of the preimage of $D$ under the $2 : 1$ map $\pi : V \to \mathbb{P}^2$ is connected. This follows from the fact that the preimage of $C_k$ is a double curve, the support of
Lemma 6.3. The resultant \( r((x_1 : x_2)(b : e)) \) vanishes to order

\[
= \sum_k \text{mult}_{C_k}(D_{(b_0 : e_0)}) \cdot \begin{cases}
\deg C_k & : (1 : 0 : 0) \not\in C_k \\
\deg C_k - 1 & : (1 : 0 : 0) \in C_k
\end{cases}
\]

at \((b : e) = (b_0 : e_0)\). 

Proof. This follows from the geometric description of the zeros of the resultant in terms of projecting the scheme-theoretic intersection of \( h = 0 \) and \( f_3g_3 = 0 \) from the point \((1 : 0 : 0)\).

We can therefore determine the relevant branch points from the resultant. This leads to the following algorithm.

Algorithm.

1. Compute the resultant \( r((x_1 : x_2)(b : e)) \) of the two polynomials \( f_3(x_0 : x_1 : x_2)g_3(x_0 : x_1 : x_2) \) and \( h((x_0 : x_1 : x_2), (b : e)) \) in one variable, say \( x_0 \).
2. Observe that \( r((x_1 : x_2)(b : e)) = c_1(b : e)c_2(b : e)s((x_1 : x_2), (b : e))^2 \), where \( c_i(b : e) \) are homogeneous polynomials each with a unique root, denoted by \((b_i : e_i)\). (If \((1 : 0 : 0)\) is in the branch curves, it may be necessary to change coordinates first.)
3. Write the Weierstrass form of \( h((x_0 : x_1 : x_2), (b : e)) \), by applying the standard transformations. This is the equation of a rational elliptic surface, and the base of the fibration is \( \mathbb{P}^1_{(b : e)} \).
4. Consider the base change \( \mathbb{P}^1_{(b : e)} \to \mathbb{P}^1_{(b : e)} \) given by \( b = \beta^2(b_1/e_1) + e^2, \quad e = \beta^2 + (e_2/b_2)e^2 \) (cf. [1,4]). Substituting this base change in the previous Weierstrass equation, one finds the Weierstrass equation of the elliptic fibration on the K3 surface \( V \) whose base is \( \mathbb{P}^1_{(b : e)} \).

6.2. The elliptic fibrations on \( S_{5,5} \). In this section we want to describe all the elliptic fibrations on \( S_{5,5} \) giving equations for each of them.

In [2] a model of \( S_{5,5} \) as a double cover of \( \mathbb{P}^2 \) was given and the elliptic fibrations induced by (generalized) conic bundles are already studied geometrically in that context. Here we explicitly describe in our context both the fibrations induced by generalized conic bundles and the ones induced by splitting genus 1 curves, giving also a Weierstrass equation for each of them.
6.2.1. Elliptic fibrations induced by splitting genus 1 pencils. The fibration 11 of Table 6.1 is induced by the class of the fiber

\[ M_1 := Q_0 + \Omega_0^{(1)} + \Omega_{1,0}^{(1)} + \Omega_2^{(1)} + Q_1 + \Omega_2^{(2)} + \Omega_{3,2}^{(2)} + \Omega_4^{(2)} + \Omega_{3,1}^{(2)} + \Omega_4^{(2)} + \Omega_{1,0}^{(2)} \]

which is the class of a fiber of type $I_{12}$. The curves $\Omega_3^{(1)}$, $\Omega_{3,2}^{(1)}$, $\Omega_2^{(1)}$, $\Omega_{3,4}^{(1)}$, $\Omega_4^{(1)}$, $Q_3$, and $\Omega_1^{(2)}$ are orthogonal to the components of the $I_{12}$-fiber and form a fiber of type $IV^*$. The classes $Q_2$, $Q_4$, $\Omega_{1,2}^{(1)}$, $\Omega_{4,0}^{(1)}$, $\Omega_{1,0}^{(2)}$, $\Omega_{2,1}^{(2)}$ are sections of the elliptic fibration induced by $|M_1|$. We observe that there are 6 curves fixed by $\iota$ among the components of the fiber of type $I_{12}$ (the curves $\Omega_j^{(j)}$ for $(i, j) = (0, 1)$, $(1, 1)$, $(2, 2)$, $(3, 2)$, $(4, 2)$, $(0, 2)$) and 4 among the components of the $IV^*$-fiber (the curves $\Omega_j^{(j)}$ for $(i, j) = (3, 1)$, $(2, 1)$, $(4, 1)$, $(1, 2)$).

The push-down of the class $M_1$ is

\[ 3h - E_1 - F_1 - G_1 - 2H_1 - E_2 - 2F_2 - G_2 - H_2 - E_3 - F_3 - G_3 - H_3 - E_{T_1} - E_{T_2} - E_5 \]

which corresponds to a pencil of cubics passing through $Q_1$ with tangent line $\ell_2$, through $Q_2$ with tangent line $m_2$, through $Q_3$, $E_{T_1}$, $E_{T_2}$, and $Q_5$. The equation of this pencil is

\[ \begin{equation}
(b x_0^2 x_1 - x_0 x_1^2 + x_1^2 x_2 + x_1 x_2^2 - 2x_0^2 x_2) + e(x_0 x_1 x_2 - x_0^2 x_2) = 0.
\end{equation} \tag{6.5} \]

The Weierstrass form of the (rational) elliptic fibration associated to the pencil (6.5) is

\[ y^2 = x^3 - \frac{1(28b^2 + 4eb + e^2)(2b + e)^2}{48} \cdot \frac{(376b^4 + 176eb^3 + 60e^2b^2 + 8e^3b + e^4)(2b + e)^2}{864}, \]

whose discriminant is $b^6(31b^2 + 4eb + e^2)(2b + e)^4/16$. This elliptic fibration has a fiber of type $I_6$ on $b = 0$ and one of type $IV$ on $(b : e) = (1 : -2)$.

The fibration 10 of Table 6.1 is induced by the class of the fiber

\[ M_2 := Q_0 + \Omega_0^{(1)} + \Omega_{1,0}^{(1)} + \Omega_2^{(1)} + \Omega_{3,2}^{(1)} + \Omega_4^{(1)} + \Omega_{3,1}^{(2)} + \Omega_4^{(2)} + Q_4 + \Omega_4^{(2)} + \Omega_{4,0}^{(2)} + \Omega_{1,0}^{(2)} \]

which is the class of a fiber of type $I_{16}$.

The push-down of the class $M_2$ is

\[ 4h - E_1 - F_1 - G_1 - 2H_1 - E_2 - F_2 - 2G_2 - H_2 - E_3 - 2F_3 - G_3 - H_3 - E_4 - 2F_4 - G_4 - H_4 - 2E_{T_2} - 2E_5 \]

which corresponds to a pencil of quartics with bitangent lines $\ell_2$ (in $Q_2$ and $Q_4$) and $\ell_3$ (in $Q_1$ and $Q_3$) and having two nodes in $E_{T_2}$ and $E_5$. The equation of this pencil is

\[ \begin{equation}
(b x_0^4 - 2bx_0^3 x_1 + bx_0^2 x_1^2 - 2bx_0^3 x_2 + (3b + 4e)x_0^2 x_1 x_2 + (-b - 4e)x_0 x_1^2 x_2 + ex_1^2 x_2 + bx_0^2 x_2^2 + (-b - 4e)x_0 x_1 x_2^2 + 2ex_1^2 x_2^2 + ex_1 x_2^3 = 0.
\end{equation} \tag{6.6} \]

Using the algorithm, we find the following Weierstrass equations for elliptic fibrations on $S_{5,5}$ induced by splitting genus 1 pencils.
elliptic fibrations

| $i$ | elliptic fibrations |
|-----|---------------------|
| 6   | $A = \frac{\beta}{48} \beta^8 - \frac{\beta}{12} \beta^3 (-\beta^2 + 2 \beta \epsilon + \epsilon^2) - \frac{1}{6} \beta^3 (-\beta^2 + 2 \beta \epsilon + \epsilon^2)^2 +$ $+ \frac{1}{12} \beta^2 (-\beta^2 + 2 \beta \epsilon + \epsilon^2)^3 - (1/48)(-\beta^2 + 2 \beta \epsilon + \epsilon^2)^4$ $B = -(1/108) \beta^{12} - (5/9) \beta^{11} \epsilon - (7/18) \beta^{10} \epsilon^2 + (28/27) \beta^9 \epsilon^3 + (7/12) \beta^8 \epsilon^4 - (11/12) \beta^7 \epsilon^5 +$ $-(35/72) \beta^6 \epsilon^6 + (1/3) \beta^5 \epsilon^7 + (5/24) \beta^4 \epsilon^8 - (5/108) \beta^3 \epsilon^9 - (1/18) \beta^2 \epsilon^{10} - (1/72) \epsilon^{11} \beta - (1/864) \epsilon^{12}$ $\Delta = (1/16) \beta^{18} (19 \beta^4 - 14 \beta^3 \epsilon - 3 \beta^2 \epsilon^2 + 4 \beta \epsilon^3 + \epsilon^4)(\epsilon + \beta)^2$ |
| 11  | $A = -(24 \epsilon^4 + \beta^3)^3 / 48$, $B = -(216 \epsilon^8 + 36 \beta^4 \epsilon^3 + \beta^4) / 864$ $\Delta = \epsilon^{12}(27 \epsilon^4 + \beta^4)^3 / 16$ |
| 10  | $A = (-\beta^8 + 16 \epsilon^4 \beta^3 - 16 \epsilon^8) / 48$, $B = -(\beta^3 - 8 \epsilon^4)(-8 \epsilon^8 - 16 \epsilon^4 \beta^3 + \beta^8) / 864$ $\Delta = \epsilon^{16} \beta^4 (2 \epsilon - \beta)(2 \epsilon + \beta)(4 \epsilon^2 + \beta^2)^2 / 16$ |

6.2.2. Elliptic fibrations induced by generalized conic bundles. Let us consider the divisors:

$N_1 = 2\Omega_0(1) + 4\Omega_0 + 6\Omega_0(2) + 5\Omega_1 + 4\Omega_1(2) + 3\Omega_2 + 2\Omega_2 + \Omega_3 + 3\Omega_4,$

$N_2 = 2\Omega_4(2) + 2\Omega_4(2) + 6\Omega_0 + 5\Omega_1 + 4\Omega_1(2) + 3\Omega_2 + 2\Omega_2 + \Omega_3 + 3\Omega_4,$

$N_3 = \Omega_0 + \Omega_4 + 3\Omega_4 + 2 \left( \Omega_0^2 + \Omega_0 + \Omega_4 + \Omega_4^2 + \Omega_4 + \Omega_1 + \Omega_1^2 + \Omega_2 + \Omega_2 + \Omega_4 + \Omega_4^2 \right),$ 

$N_4 = \Omega_4^2 + 2\Omega_4 + 3\Omega_0 + 4\Omega_1 + 3\Omega_2 + 2\Omega_2 + \Omega_3 + 2\Omega_4 + 2\Omega_4,$

$N_5 = \Omega_1 + \Omega_4 + \Omega_4 + 2 \left( \Omega_0^2 + \Omega_0 + \Omega_4 + \Omega_4 + \Omega_4 + \Omega_4 + \Omega_4 + \Omega_4^2 + \Omega_4 + \Omega_4 \right).$

The linear system $|N_i|$ induces the elliptic fibration number $i$ of the Table (3.1), indeed the divisor $N_1$ corresponds to an elliptic fibration with a fibre of type $II^*$, $III^*$, $I^{12}$, $I_8^*$ if $i = 1, 2, 3, 4, 8$ respectively, so $N_3$ (resp. $N_8$) corresponds to the unique fibration in Table (3.1) with a fibre of type $I_2^*$ (resp. $I_8^*$), i.e. the fibrations 3 (resp. 8). A priori, $N_1$ could correspond either to the fibration 1 or to the fibration 2 (which are the fibrations which admit at least a fibre of type $II^*$). To distinguish among these cases we consider the other reducible fibers: the curves orthogonal to $N_1$ are $\Omega_{h,j}^{(1)}$, for $h, j \in \{1, 2, 3, 4\}$, $h < j$, $\Omega_{k}^{(1)}$ for $k = 1, 2, 3, 4$, $Q_2$ and $Q_4$ and they span the lattice $\mathbb{E}_8$, so $N_1$ corresponds to the fibration 1 in Table (6.1); the curves orthogonal to $N_2$ are $\Omega_{h,j}^{(1)}$, for $h, j \in \{1, 2, 3, 4\}$, $h < j$, $\Omega_{k}^{(1)}$ for $k = 1, 2, 3, 4$ and $Q_2$ and they span the lattice $D_{10}$, so $N_2$ corresponds to the fibration 2 in Table (6.1).

Let us now consider the fibration $N_4$. The fiber associated to $N_4$ is a fiber of type $III^*$. The curves $\Omega_2(1)$ and $\Omega_4(1)$ are sections of the fibration. The curves $\Omega_2(1)$, $\Omega_2$, $\Omega_2(2)$, $\Omega_2$, $\Omega_4(2)$, $\Omega_4(1)$, $Q_2$, $Q_4$ are orthogonal to $N_4$ and are the components of another fiber of type $III^*$. This implies that $|N_4|$ is the fibration 4 in Table (6.1), and that the unique other reducible fiber is of type $I_5^*$. The curves $Q_3$, $\Omega_3(1)$, $\Omega_3(1)$ and $\Omega_3(1)$ are orthogonal to $N_4$ and span a lattice isometric to $D_4$. So they are components of the $I_5^*$-fiber in the fibration $|N_4|$. A $I_5^*$-fiber has five components, four of them are $Q_3$, $\Omega_3(1)$, $\Omega_4(1)$ and $\Omega_5(1)$, the fifth component is another curve, say $V_1$. So that we have a special fiber of the fibration $|N_4|$, which is $2\Omega_4(1) + \Omega_4(1) + \Omega_4(1) + Q_3 + V_1$. Hence we can express the class of the curve $V_1$ as $N_4 - (2\Omega_4(1) + \Omega_4(1) + \Omega_4(1) + Q_3)$. From this expression one can compute all the intersection numbers of $V_1$ with all
the curves $\Omega_{1,0}^{1}, \Omega_{1,0}^{2}$, and $Q_k$. One can also observe that since $V_1$ is a component of a fiber of the fibration $|N_4|$, it is orthogonal to all the components of the two other reducible fibers of the same fibration, i.e. to the components of the III*-fibers.

Let us now consider the class:

$$N_7 := \Omega_{1,0}^{1} + \Omega_{1,0}^{2} + V_1 + \Omega_{1,3}^{1} + 2(\Omega_{1,0}^{1} + Q_0 + \Omega_{1,0}^{2} + \Omega_{1,0}^{2} + \Omega_{1,0}^{2} + \Omega_{2,1}^{2} + \Omega_{3,2}^{2} + \Omega_{3,2}^{2} + \Omega_{4,2}^{2} + \Omega_{4,2}^{2} + Q_2 + \Omega_{2,1}^{2} + \Omega_{3,2}^{2} + \Omega_{3,2}^{2}).$$

It is the class of the elliptic fibration 7 in the Table 6.1 since it is the class of a fiber of an elliptic fibration on $S_{5,5}$ with a fiber of type $I_{14}^*$. All the classes $N_i$ for $i = 1, 2, 3, 4, 7, 8$ considered above correspond to generalized conic bundles which can be written in the following way in terms of the classes on $\hat{R}$:

| $i$ | $(\pi_*(N_i))/2$ |
|-----|-----------------|
| 1   | $4h - (E_2 + F_2 + G_2 + H_2) - (2E_3 + 3F_3 + 3G_3 + 2H_3) - 2(E_4 + 2F_4 + G_4 + H_4) - E_5$ |
| 2   | $4h - (2E_2 + 2F_2 + 2G_2 + 3H_2) - 2(E_4 + 2F_4 + G_4 + H_4) - (E_3 + 2F_3 + G_3 + H_3) - E_5$ |
| 3   | $4h - (2E_1 + 2F_1 + 2G_1 + 3H_1) - (E_4 + 2F_4 + G_4 + 2H_4) - (E_3 + 2F_3 + G_3 + H_3) - E_5$ |
| 4   | $2h - (E_1 + F_1 + 2G_1 + H_1) - (E_3 + 2F_3 + G_3 + H_3)$ |
| 7   | $7h - 3(E_1 + F_1 + 2G_1 + H_1) - (E_2 + 2F_2 + G_2 + H_2) + 2E_3 + 2F_3 + G_3 + H_3)$ |
| 8   | $4h - 2(E_1 + F_1 + 2G_1 + H_1) - (2E_2 + 3F_2 + 2G_2 + 2H_2) + (E_4 + 2F_4 + G_4 + H_4) - (E_3 + 2F_3 + G_3 + 3H_3)$ |

This allows to compute explicitly the equations of pencils of singular rational curves in $\mathbb{P}^2$ corresponding to our elliptic fibrations on $S_{5,5}$.

| $i$ | pencils in $\mathbb{P}^2$ |
|-----|-----------------|
| 1   | $a(x_0^2 - x_1 x_1 + 3x_0^2 x_1 - 2x_0^2 x_2 + 6x_0^2 x_2 - 3x_0 x_1 x_2^2 - 4x_0 x_1 x_2^2 + 4x_0 x_1 x_2^2 + x_1 x_2^2 + x_2^2) + gx_0 x_1 x_2^2 |
| 2   | $n(x_0^2 - 2x_0 x_1 + 2x_0 x_1 + 7x_0 x_1 x_2 - 3x_0 x_1 x_2 - 4x_0 x_1 x_2 - 6x_0 x_1 x_2 + 8x_0 x_1 x_2 + 8x_1 x_2 + x_1 x_2 + x_2) + m(8x_1^2 x_2 x_0 - 8x_1^2 x_2)$ |
| 3   | $f(-x_0^2 + x_0 x_1 x_2 + x_0 x_1 x_2 - x_1 x_2^2) + n(x_0^2 + 2x_0 x_1 x_2 - x_0^2 x_2 - x_0 x_1 x_2^2)$ |
| 4   | $\tau x_0^2 + \sigma(x_0 x_2 - x_1 x_2)$ |
| 7   | $s(x_0^2 - 2x_0 x_1 + 3x_0 x_1 x_2 - x_0 x_1 x_2 - 2x_0 x_1 x_2 - 2x_0 x_1 x_2 - 2x_0 x_1 x_2 + x_0 x_1 x_2 + x_0 x_1 x_2 + x_0 x_1 x_2 + x_0 x_1 x_2)$ |

Now it remains to find the Weierstrass equations of the elliptic fibrations on $S_{5,5}$ corresponding to the linear systems $(\pi_*(N_i))/2$ on $\hat{R}$. In case 4, the curves which are fibers of the conic bundle have degree 2, so we can directly apply the first algorithm in Section 5.2. In cases 1, 2, 3, and 8 the curves are quartics which satisfy condition (1) and so we may apply the second algorithm in Section 5.2. The
rational parameterizations and induced Weierstrass equations are given by

\[(6.8)\]

| i | rational parameterization | elliptic fibration |
|---|--------------------------|-------------------|
| 1 | \[x_0 = -agp^2 - 2agp - agp\] | \[A = -3a^2g^4, B = a^2g^5 + a^5g^2\] |
|   | \[x_1 = -agp^2 + 2agp - agp\] | \[\Delta = -432a^{10}n^{10}(a - g)^2(a + g)^2\] |
|   | \[x_2 = agp^2 + agp - g^2p^2\] |                               |
| 2 | \[x_0 = -64agp^2 + 8agp^3 - 8agp^2\] | \[A = 108n^2a^4\left(-n^2 + 384m^2\right)\] |
|   | \[x_1 = -64agp^2 + 16agp^3\] | \[B = -432m^3n^2\left(n^4 - 576m^2n^2 + 55296m^4\right)\] |
|   | \[x_2 = -n^2p^2 - 16agp^3 + 2n^2p - n^2\] | \[\Delta = 57063042868384m^{10}n^2\left(n^2 - 432m^2\right)\] |
| 3 | \[x_0 = p(-np + fp + n)(-np^2 + fp^2 + fp - n + f)\] | \[A = (3f)^4 - 18fn + 36f n^2 - 24f^5n + 3f^4n^6 + 6f n^6 - n^6);\] |
|   | \[x_1 = (p + 1)(-n + f)p^2\left(-np + fp + n\right)\] | \[27(f - n)^2\] |
|   | \[x_2 = (-np^2 + fp^2 + fp - n + f)^2\] | \[B = (9f^6 - 54f^6n + 117f^4n^2 - 108f^3n^3 + 39f^2n^4 - 6fn^5 + n^6);\] |
|   | \[\Delta = -503056(n - f)(n - 2f)(2n - f)^2(n - f)^2(n - f)^2\] | \[27n(f - n)^3(3f - 6fn + 2n^2)\] |
| 4 | \[x_0 = (p - 1)(sp + t)(sp^2 - sp - t)\] | \[A = \tau^2(1 + \tau)^2; B = 0,\] |
|   | \[x_1 = sp^2(sp^2 - sp - t)\] | \[\Delta = 4\tau^2(1 + \tau)^6\] |
|   | \[x_2 = (p - 1)(sp + t)(sp - t)\] | \[B = -27\tau^2s^2(2s^2 + 8s^2t^2 - t^4)\] |
|   |                               | \[\Delta = 8503056s^6t^4(2s^2 + 4t^4)\] |

The fibration induced by \(|N_7|\) is the unique elliptic fibration on a K3 surface with a fiber of type \(I^2_4\) (which is a maximal fiber, since if a K3 surface admits an elliptic fibration with this reducible fiber, then this is the unique reducible fiber). So it suffices to know the equation of this elliptic fibration, which is classically known \cite{[3]} Theorem 1.2. Hence for \(|N_7|\) we only re-write here the known equation, a part from the fact that we chose the parameters over \(\mathbb{P}^1_{(\tau, \sigma)}\) in such a way that 4 fibers of type \(I_1\) are over the points \((\tau : \sigma) = ((\pm \sqrt{-26 \pm 14i\sqrt{7}})/4 : 1)\). These values correspond to the septic in \(|N_7|\) which are tangent to \(m_2\) in a smooth point. We therefore have equation:

\[(6.9)\]

\[A = \tau^2(-12\sigma^6 - (3/8)\sigma^4\tau^2 - (15/2048)\sigma^2\tau^4 - (9/262144)\tau^6),\]

\[B = \tau^3\sigma(-16\sigma^8 - (3/4)\tau^2\sigma^6 - (21/1024)\sigma^4\tau^4 - (35/131072)\tau^6\sigma^2 - (63/33554432)\tau^8),\]

\[\Delta = -(729/4503596)(27370496)\tau^{20}(2048\sigma^4 + 52\tau^2\sigma^2 + \tau^4).\]

We note that it is possible to obtain such an equation using our techniques. Indeed one may find a rational parameterization of the septic plane curves of the generalized conic bundle by rational cubic curves, and from there the computation follows in the same way as above. We omit this computation here as the equation is already in the literature.

7. The K3 surface \(X_{5,5}\) and its elliptic fibrations

The K3 surface \(X_{5,5}\) is very well-known and studied, in particular since its Néron–Severi group allows to describe the moduli spaces of K3 surfaces with an elliptic fibration with a 5-torsion section in terms of \(L\)-polarized K3 surfaces, see \cite{[5]}. Indeed, if a K3 surface admits an elliptic fibration with a 5-torsion section, then the lattice \(U \oplus M\) has to be primively embedded in its Néron–Severi lattice, where \(M\) is an overlattice of index 5 of a root lattice. The lattice \(M\) is known to be an overlattice of index 5 of \(A_4^4\) and so the lattice \(U \oplus M\) is isometric to the Néron–Severi lattice of \(X_{5,5}\). Hence the moduli space of the K3 surfaces which are \(NS(X_{5,5})\)-polarized coincides with the moduli space of the K3 surfaces which admit an elliptic fibration with a 5-torsion section.
7.1. The list of all the elliptic fibrations. The transcendental lattice of $X_{5,5}$ is known to be $T_X \simeq U \oplus U(5)$, see e.g. [3]. This allows to apply the Nishiyama method in order to classify (at least lattice theoretically) the elliptic fibrations on $X_{5,5}$. This method is studied and applied in several papers, and we do not intend to describe it in details. Here we just observe that we can apply the method using $A_4 \oplus A_4$ as the lattice $T$, so that $T$ is a negative-definite lattice with the same discriminant form as the one of the transcendental lattice $T_X$ and whose rank is $\text{rank}(T) = \text{rank}(T_X) + 4$. Then one has to find the primitive embeddings of $A_4 \oplus A_4$ in the Niemeier lattice up to isometries, and this can be done by embedding $T$ into the root lattice of the Niemeier lattices. The list of the Niemeier lattices and the possible embeddings of root lattices in Niemeier lattices up to the Weyl group can be found in [9] (see also [7]). In particular one has that $A_4$ embeds primitively in a unique way (up to the action of the Weyl group) in $A_n$ for $n > 4$, in $D_m$ for $m > 4$, in $E_h$ for $h = 6, 7, 8$, see [9] Lemmas 4.2 and 4.3. On the other hand $A_4 \oplus A_4$ has a primitive embedding in $A_n$ for $n \geq 9$, in $D_m$ for $m \geq 10$, and has no primitive embeddings in $E_h$ for $h = 6, 7, 8$, see [9] Lemma 4.5. All these primitive embeddings are unique with the exception of $A_4 \oplus A_4 \hookrightarrow D_{10}$, for which there are two possible primitive embeddings, see [9] Page 325, just before Step 3. The orthogonal complement of the embedded copy of $A_4 \oplus A_4$ in the root lattice of each Niemeier lattices is a lattice $L$ which can be computed by [9] Corollary 4.4 and which encodes information about both the reducible fibers and the rank of the Mordell–Weil group of the elliptic fibrations. In particular the root lattice of $L$ is the lattice spanned by the irreducible components of the reducible fibers orthogonal to the zero section. More precise information on the sections can be obtained by a deeper analysis of these embeddings, but this is outside the scope of this paper. So in the following list we give the root lattice of the Niemeier lattice that we are considering, the embeddings of $A_4 \oplus A_4$ in this root lattice, the root lattices of the orthogonal complement, and in the last two columns the properties of the associated elliptic fibration. This gives the complete list of the types of elliptic fibrations on $X_{5,5}$:

| Niemeier Lattice | Embeddings of $A_4 \oplus A_4$ | Orthogonal Complement | Properties |
|------------------|-------------------------------|------------------------|------------|
| $A_n$ for $n > 4$ | $A_4 \oplus A_4$ primitively | $L$ determined by [9]  |            |
| $D_m$ for $m > 4$ | $A_4 \oplus A_4$ primitively | $L$ determined by [9]  |            |
| $E_h$ for $h = 6, 7, 8$ | $A_4 \oplus A_4$ primitively | $L$ determined by [9]  |            |
| $D_{10}$          | $A_4 \oplus A_4 \hookrightarrow D_{10}$ | $L$ determined by [9]  |            |
| n° | Niemeier | embedding(s) | roots orthogonal | singular fibers | rk(MW) |
|----|----------|--------------|-----------------|----------------|--------|
| 1  | $E_8^3$  | $A_4 \subset E_8$ $A_4 \subset E_8$ | $A_4 \oplus A_4 \oplus E_8$ | $2I_5 + II^* + 2I_3$ | 0 |
| 2  | $E_8 \oplus D_{16}$ | $A_4 \subset E_8$ $A_4 \subset D_{16}$ | $A_4 \oplus D_{11}$ | $I_5 + I_3 + 6I_3$ | 1 |
| 3  | $E_8 \oplus D_{16}$ | $A_4 \oplus A_4 \subset D_{16}$ | $E_8 \oplus D_6$ | $II^* + I_3^* + 6I_3$ | 2 |
| 4  | $E_7 \oplus D_{10}$ | $A_4 \subset E_7$ $A_4 \subset D_{10}$ | $A_2^2 \oplus D_{10}$ | $2I_2 + I_3^* + 6I_3$ | 2 |
| 5  | $E_7 \oplus D_{10}$ | $A_4 \subset E_7$ $A_4 \subset D_{10}$ | $E_7 \oplus A_3 \oplus D_5$ | $III^* + I_3 + I_1^* + 5I_1$ | 2 |
| 6  | $E_7 \oplus D_{10}$ | $A_4 \oplus A_4 \subset D_{10}$ | $E_7^*$ | $2III^* + 6I_1$ | 2 |
| 7  | $E_7 \oplus D_{10}$ | $A_4 \oplus A_4 \subset D_{10}$ | $E_7^*$ | $2III^* + 6I_1$ | 2 |
| 8  | $E_7 \oplus A_{17}$ | $A_4 \subset E_7$ $A_4 \subset A_{17}$ | $A_2 \oplus A_{12}$ | $I_3 + I_{13} + 8I_3$ | 2 |
| 9  | $E_7 \oplus A_{17}$ | $A_4 \oplus A_4 \subset A_{17}$ | $E_7 \oplus A_7$ | $III^* + I_8 + 7I_1$ | 2 |
| 10 | $D_{24}$ | $A_4 \oplus A_4 \subset D_{24}$ | $D_{14}$ | $I_{10} + 8I_1$ | 2 |
| 11 | $D_{12} \oplus D_{12}$ | $A_4 \subset D_{12}$ $A_4 \subset D_{12}$ | $D_7 \oplus D_7$ | $2I_9^* + 6I_1$ | 2 |
| 12 | $D_{12} \oplus D_{12}$ | $A_4 \subset D_{12}$ $A_4 \subset D_{12}$ | $D_{12} \oplus A_2^7$ | $I_5^* + 2I_2 + 6I_3$ | 2 |
| 13 | $D_8^3$ | $A_4 \subset D_8$ $A_4 \subset D_8$ | $D_8 \oplus A_3 \oplus A_3$ | $I_5^* + 2I_4 + 6I_3$ | 2 |
| 14 | $D_8 \oplus A_{15}$ | $A_4 \subset D_8$ $A_4 \subset A_{15}$ | $D_4 \oplus A_{10}$ | $I_3^* + I_4 + 7I_1$ | 2 |
| 15 | $D_8 \oplus A_{15}$ | $A_4 \oplus A_4 \subset A_{15}$ | $D_9 \oplus A_5$ | $I_9^* + I_8 + 7I_1$ | 2 |
| 16 | $E_6^8$ | $A_4 \subset E_6$ $A_4 \subset E_6$ | $A_2^3 \oplus E_6^*$ | $2I_5^* + 1V^* + 4I_1$ | 2 |
| 17 | $E_6 \oplus D_7 \oplus A_{11}$ | $A_4 \subset E_6$ $A_4 \subset D_7$ | $A_4 \oplus A_{11}$ | $3I_2 + I_{12} + 6I_1$ | 2 |
| 18 | $E_6 \oplus D_7 \oplus A_{11}$ | $A_4 \subset E_6$ $A_4 \subset A_{11}$ | $A_1 \oplus D_7 \oplus A_6$ | $I_2^* + I_6 + 6I_1$ | 2 |
| 19 | $E_6 \oplus D_7 \oplus A_{11}$ | $A_4 \subset D_7$ $A_4 \subset A_{11}$ | $E_6 \oplus A_2^6 \oplus A_6$ | $IV^* + 2I_4 + 5I_3$ | 2 |
| 20 | $E_6 \oplus D_7 \oplus A_{11}$ | $A_4 \oplus A_4 \subset A_{11}$ | $E_6 \oplus D_7 \oplus A_1$ | $IV^* + I_7^* + 2I_2 + 5I_1$ | 2 |
| 21 | $D_6^4$ | $A_4 \subset D_6$ $A_4 \subset D_6$ | $D_2^6$ | $2I_2^* + 8I_1$ | 4 |
| 22 | $D_6 \oplus A_9^2$ | $A_4 \subset D_6$ $A_4 \subset A_9$ | $A_4 \oplus A_9$ | $I_5 + I_{10} + 9I_1$ | 3 |
| 23 | $D_6 \oplus A_9^2$ | $A_4 \subset A_9$ $A_4 \subset A_9$ | $D_6 \oplus A_4 \oplus A_4$ | $I_2^* + 2I_5 + 6I_1$ | 2 |
| 24 | $D_6 \oplus A_9^2$ | $A_4 \oplus A_4 \subset A_9$ | $D_6 \oplus A_9$ | $I_2^* + I_{10} + 6I_1$ | 1 |
| 25 | $D_2 \oplus A_7^2$ | $A_4 \subset D_5$ $A_4 \subset D_5$ | $A_2^7$ | $2I_8 + 8I_1$ | 2 |
| 26 | $D_2 \oplus A_7^2$ | $A_4 \subset D_5$ $A_4 \subset A_7$ | $A_7 \oplus D_5 \oplus A_2$ | $I_8 + I_7^* + I_7 + 6I_1$ | 2 |
| 27 | $D_2 \oplus A_7^2$ | $A_4 \subset A_7$ $A_4 \subset A_7$ | $D_2^5 \oplus A_2^2$ | $2I_5^* + 2I_4 + 4I_1$ | 2 |
| 28 | $A_8^3$ | $A_4 \subset A_8$ $A_4 \subset A_8$ | $A_2^3 \oplus A_8$ | $2I_4 + I_8 + 7I_1$ | 2 |
| 29 | $A_4 \oplus A_4 \subset A_2$ | $A_4 \subset A_4$ $A_4 \subset A_2$ | $A_{14}$ | $I_{15} + 9I_1$ | 2 |
| 30 | $A_2^7$ | $A_4 \subset A_2$ $A_4 \subset A_12$ | $A_2^7$ | $2I_8 + 8I_1$ | 2 |
| 31 | $A_2^7$ | $A_4 \subset A_4$ $A_4 \subset A_{12}$ | $A_2 \oplus A_{12}$ | $I_3 + I_{13} + 8I_1$ | 2 |
| 32 | $A_2^7$ | $A_4 \subset A_4$ $A_4 \subset A_5$ | $D_4 \oplus A_2^5$ | $I_5^* + 2I_6 + 6I_1$ | 2 |
| 33 | $A_4^4$ | $A_4 \subset A_4$ $A_4 \subset A_5$ | $A_4^2 \oplus A_6^2$ | $2I_2^* + 2I_7 + 6I_1$ | 2 |
| 34 | $A_4^4$ | $A_4 \subset A_4$ $A_4 \subset A_4$ | $A_4^2$ | $4I_5 + 4I_1$ | 0 |

Observe that lines 6 and 7 correspond to the two different embeddings of $A_4 \oplus A_4$ in $D_{10}$. The K3 surface $X_{5,5}$ is obtained as double cover of a rational surface $R_{5,5}$ branched on two smooth fibers, so there are no elliptic fibrations induced by generalized conic bundles or by splitting genus 1 pencils, see [3]. So an elliptic fibration on $X_{5,5}$ is either induced by a conic bundle on $R_{5,5}$ or it is of type 3.

Putting together these considerations with the results of Sections 4 and 6 we proved the following proposition.

**Proposition 7.1.** The elliptic fibrations on $X_{5,5}$ are of 34 types, listed in Table 7.1. The fibration in line 34 of Table 7.1 is induced by $E_R$ and its equation is given in Section 4. The fibrations of lines 22, 30 and 32 are induced by conic bundles on $R_{5,5}$ and their equations are given in Section 5. The fibrations on $X_{5,5}$ are of type 3.
7.2. Fibration of type 3: an example, the fibration 26. The aim of this section is to construct explicitly an example of an elliptic fibration of type 3 and to discuss the geometry of the non complete linear system on \( \mathbb{P}^2 \) which induces this fibration.

The divisor
\[
D_1 := \Omega_0^{(2,2)} + \Omega_0^{(1,1)} + 2Q_0 + 2\Omega_0^{(2,1)} + \Omega_1^{(2,1)} + \Omega_4^{(2,1)}
\]
corresponds to the class of the fiber of a fibration which has one reducible fiber of type \( I_1' \), thus \( |D_1| \) is one of the fibrations 5,26,27 in Table (7.1). The curves \( \Omega_2^{(2,1)}, \Omega_3^{(2,1)}, Q_2, Q_3, \Omega_1^{(2,2)}, \Omega_4^{(2,2)}, \Omega_1^{(1,1)}, \Omega_4^{(1,1)} \) are sections of the fibration \( |D_1| \).

Assuming that \( \Omega_2^{(2,1)} \) is the zero section there is fiber whose non trivial components are \( \Omega_2^{(2,2)}, \Omega_3^{(2,2)}, Q_4, \Omega_4^{(1,2)}, \Omega_1^{(1,2)}, \Omega_3^{(1,2)} \). So there is a fiber of type \( I_8 \) and \( |D_1| \) is the fibration 26 in (7.1) and there is a fiber of type \( I_3 \) whose non trivial components are \( \Omega_2^{(1,1)}, \Omega_3^{(1,1)} \).

Denoted by \( \pi : X_{5,5} \to R_{5,5} \), we have \( \pi(Q_i) = P_i \) and \( \pi(\Omega_i^{(j,1)}) = \Omega_i^{(j,2)} = \Theta_i^{(j)} \), for \( j = 1, 2 \). In particular \( \iota(\Omega_i^{(j,1)}) = \Omega_i^{(j,2)} \), thus \( \iota(D_1) \neq D_1 \) and indeed \( D_2 := \iota(D_1) \) is
\[
D_2 := \Omega_0^{(2,1)} + \Omega_0^{(1,2)} + 2Q_0 + 2\Omega_0^{(2,2)} + \Omega_1^{(2,2)} + \Omega_4^{(2,2)}.
\]

We observe that \( \Omega_0^{(2,1)} D_1 = 0, \Omega_2^{(1,2)} D_1 = 2, Q_0 D_1 = 0, \Omega_0^{(2,2)} D_1 = 0, \Omega_1^{(2,2)} D_1 = 1, \Omega_4^{(2,2)} D_1 = 1 \), and thus \( D_2 D_1 = 0 + 2 + 0 + 1 + 1 = 4 \).

So \( D_1 D_2 = 4 \) and \( (D_1 + D_2)^2 = 8 \). In particular a smooth member of the linear system \( |D_1 + D_2| \) is a curve of genus 5.

We are interested in the class of the curve \( \pi(D_1 + D_2) \). By the projection formula \( \pi_*(D_1 + D_2) = 2\pi(D_1 + D_2) \), so we are looking for \( \frac{1}{2} \pi_*(D_1 + D_2) \). Since \( \pi(D_1) = \pi(D_2), \frac{1}{2} \pi_*(D_2 + D_2) = \pi_*(D_1) = \pi_*(D_2) \).

We recall that the map \( \pi \) restricted to \( \Omega_i^{(j,1)} \) is a 1 : 1 map to \( \Theta_i^{(j)} \), and similarly the map \( \pi \) restricted to \( \Omega_i^{(j,2)} \) is a 1 : 1 map to \( \Theta_i^{(j)} \). On the other hand the map \( \pi \) restricted to the sections \( Q_i \) is a 2 : 1 map to the section \( P_i \). So
\[
\pi_*(D_1) = \Theta_0^{(2)} + \Theta_0^{(1)} + 4P_0 + 2\Theta_0^{(2)} + \Theta_1^{(2)} + \Theta_4^{(2)} = 3\Theta_0^{(2)} + \Theta_1^{(2)} + \Theta_4^{(2)} + \Theta_0^{(1)} + 4P_0.
\]

Hence by (2.4)
\[
\pi_*(D_1) = 3E_1 + \ell_1 + \ell_2 + m_1 + 4F_1 = 3h - E_2 - F_2 - E_Q - E_4 - 2F_4 - E_5 - F_5,
\]
which is the class of the strict transforms of cubics in \( \mathbb{P}^2 \) passing through \( Q_2, Q_3, Q_4 \) with tangent \( \ell_2 \), and \( Q_5 \).

The equation of the cubics satisfying these properties is
\[
(7.2) \quad ax_0^3 + bx_0^2x_1 + (-a - b)x_0x_1^2 + dx_1^2x_2 + cx_0x_1x_2 + fx_0^2x_2 + (-3a + 2d)x_0x_2^2 + (a - e - f)x_1x_2^2 + (d + 2a)x_2^3 = 0.
\]

This equation depends on 5 parameters (4 projective parameters) and specializes to equations of cubics which split on the double cover and induces elliptic fibrations on \( X_{5,5} \).

The generic cubic \( c_3 \) as in equation (7.2) is a cubic in \( \mathbb{P}^2 \). We recall that \( X_{5,5} \) is the double cover of \( \mathbb{P}^2 \) branched along the reducible sextic \( c_6 \) whose equation is \( f_3g_3 = 0 \) for two cubics \( f_3 \) and \( g_3 \). So \( c_3 \) and \( c_6 \) meet in 18 points in \( \mathbb{P}^2 \) counted with multiplicity. Recall that \( c_6 \) is singular at \( Q_2, Q_3, Q_4, \) and \( Q_5 \) and in \( Q_4, c_6 \)
is the union of two cubics, both with tangent direction \( \ell_2 \). Hence \( c_4 \) intersects \( c_6 \) in \( Q_2, Q_3, Q_5 \) with multiplicity 2, and in \( Q_4 \) with multiplicity 4. Outside these points, \( c_3 \) and \( c_6 \) intersect in \( 18 - 2 - 2 - 2 - 4 = 8 \) points. The inverse image of \( c_3 \) on \( X_{5,5} \) is a double cover of \( c_3 \) branched in 8 points. Since generically \( c_3 \) is a smooth cubic in \( \mathbb{P}^2 \), it has genus 1 and then its inverse image on \( X_{5,5} \) has genus \( g \) such that \( 2g - 2 = 2(0) + 8 \). So \( g = 5 \).

We already observed that \( c_6 \) is the union of two smooth cubics in \( \mathbb{P}^2 \), which are the image of the branch curves of the double cover \( X_{5,5} \to R_{5,5} \). Denoting by \( b_1 : f_1 = 0 \) and \( b_2 := g_1 = 0 \) these two cubics, \( c_3 \) intersects \( b_1 \) in nine points, five of which are \( Q_2, Q_3, Q_4 \) with tangent \( \ell_2 \), and \( Q_5 \). So \( c_3 \) and \( b_1 \) generically intersect in four other points. In the case \( c_3 \) splits in the double cover (which is the case in which \( c_3 \) is the image both of \( B_1 \) and \( B_2 \)), these four points are either one point with multiplicity 4 or two points with multiplicity 2. The strict transform of \( b_1 \) (resp. \( b_2 \)) on \( R_{5,5} \) is a smooth fiber of the fibration on \( R_{5,5} \) and its pullback to \( X_{5,5} \) is a smooth fiber, denoted by \( B_1 \) (resp. \( B_2, B_3, B_4 \)) of the fibration induced on \( X_{5,5} \) by the one on \( R_{5,5} \). Since a section of this fibration is \( Q_0, B_1Q_0 = B_2Q_0 = 1, B_3Q_0^{(1,5)} = 0 \) and thus \( D_1B_1 = D_1B_2 = D_2B_1 = D_2B_2 = 2 \). In particular \( D_1 \) and \( D_2 \) intersect in four points, two on \( B_1 \) and two on \( B_2 \). Considering the image of these curves in \( \mathbb{P}^2 \), one realizes that if \( c_3 \) is the image of \( D_1 \), then it intersects \( b_1 \) (resp. \( b_2 \)) in two points each with multiplicity 2.

So, theoretically, in order to find the specializations of a curve \( c_3 \) which is the image of \( D_1 \), one has to require that the intersection \( c_3 \cap b_1 \) consists of the points \( Q_2, Q_3, Q_4 \) with tangent \( \ell_2 \), and \( Q_5 \), and of two other points each with multiplicity 2.

As in the previous context one can compute the resultant between the equation of the cubics \( c_3 \) and the branch locus of the double cover \( X_{5,5} \to \mathbb{P}^2 \), given in \([4,7]\). Since not all the curves in the linear system \(|c_3|\) split in the double cover, the resultant of the equation of \( c_3 \) and the equation of the branch locus of \( X \to \mathbb{P}^2 \) is not the square of a polynomial. Nevertheless one recognizes some factors with even multiplicity (which correspond to the conditions that \( c_3 \) passes with a certain multiplicity through a certain base point of the pencil of cubics from which \( R_{5,5} \) arises) and one can also observe that for certain choices of the values \((a, d, e, f)\) the resultant becomes a square. For examples one observes that for \( f = -a - d - e \) the resultant with respect to \( x_1 \) is

\[
\begin{align*}
&x_0^2(x_0 - x_2)^6(x_0x_2(6m + am - a + dm) + x_0^2(am + bm) - x_0^2(d - 2a))^2 \\
&\quad \times (x_0x_2(6l + al - a + dl) + x_0^2(al + bl) - x_0^2(d - 2a))^2
\end{align*}
\]

so in this case we know that the intersection between the generic member of \(|c_3|\) and the branch curve is always with even degree, which is the necessary condition to have a splitting in any point.
