Abstract: The rising costs of building construction in developing countries have been a source of concern to government and private developers. This study investigated the use of clay soil as partial replacement for fine aggregate in the concrete production. Clay was used to replace fine aggregates from 0% (conventional), 5%, 10% and 15% with the concrete of grade M 20. For this study, concrete cubes measuring 150 x 150 x 150mm and cylinders measuring 150 x 300mm were casted and their compressive strengths and split tensile strengths were evaluated at 7, 14 and 28 days. From this study, it has been encountered that the increase in percentage of clay in concrete cubes and cylinders led to a corresponding reduction in compressive and split tensile strength values due to the reduction in the bond strength in-between the concrete ingredients. It is overcome by, Alumina powder and Sodium Phosphate which is considered as the materials that provide better bond strength has been considered as additive admixtures to the concrete. These two ingredients Alumina & Sodium Phosphate were added to the clay-concrete from 5%, 10% and 15% with water cement ratio as 0.5. From the results obtained from this new clay-concrete with bonding admixtures, the compressive strength and split tensile strength has been found to increase gradually by increase in the admixture to the concrete. It is also to be noted that the increase in compressive and split tensile strength of clay-concrete has crossed the strength of the conventional concrete with a considerable value. So, it could be concluded as that the clay can be used as a replacement to fine aggregate in concrete with bonding admixtures to get a hybrid concrete with better performance than the conventional concrete.

Keywords: Compressive strength, Split tensile strength, EDAX result, Alumina powder, Sodium phosphate

1. Introduction

Concrete is a construction material which is composed of three main materials, these being cement, water and aggregates (sand, natural gravel or crushed stone). Sometimes, an admixture, this being an additional material, is added in order to change or modify certain properties (such as water-repellent, on colouring agent or to retard a hasten setting) of concrete. The chemically active constituent of concrete is cement. The reactivity of cement is only guaranteed and achieved on mixing it with water. Aggregates do not have a role to play in the chemical reactions within concrete but they are very useful because they act as economic filler materials with good resistance to volume changes, which occur in concrete after mixing. Another important aspect of aggregates is that they improve the durability of concrete. Concrete aggregates can sometimes contain impurities like clay particles which can have an impact on the concrete properties.

Clay coatings consist of clay particles that are held tightly to aggregate surface. Because the material usually adheres to the aggregate even after the concrete is mixed, it is believed to interfere with the aggregate-cement paste bond. Unlike clay coating, dust coating are easily removed during mixing and affect concrete performance by increasing the amount of fineness dispersed in the mix.

Coatings containing clay, silt, and organic matter are found naturally in the overlying layers of the deposit or are artificially placed on the aggregate during processing. This article is limited to the impact of clay particles on concrete compressive strength.

1.1. Clay

Clays are distinguished from other fine-grained soils by differences in size and mineralogy. Silts, which are fine-grained soils that do not include clay minerals, tend to have larger particle sizes than clays. There is, however, some overlap in particle size and other physical properties, and many naturally occurring deposits include both silts and clay. The distinction between silt and clay varies by discipline. Geologists and soil scientists usually consider the separation to occur at a particle size of 2 μm (clays being finer than silts), sedimentologists often use 4–5 μm, and colloid chemists use 1 μm. Geotechnical engineers distinguish between silts and clays based on the plasticity properties of the soil, as measured by the soils’ Atterberg limits. ISO 14688 grades clay particles as being smaller than 2 μm and silt particles as being larger.

1.2. Properties of Clay

Clay is one of the oldest building materials on Earth, among other ancient, naturally-occurring geologic materials such as stone and organic materials like wood. Between one-half and
two-thirds of the world's population, in traditional societies as well as developed countries, still live or work in a building made with clay as an essential part of its load-bearing structure. Also a primary ingredient in many natural building techniques, clay is used to create adobe, cob, cordwood, and rammed earth structures and building elements such as wattle and daub, clay plaster, clay render case, clay floors and clay paints and ceramic building material. Clay was used as a mortar in brick chimneys and stone walls where protected from water.

1.3. Alumina Powder

![Alumina Powder Reaction]

Native Alumina (Al₂O₃) is found as the mineral corundum. Most bauxite is refined by the Bayer process to remove impurities and produce a nominal 99.5% Al₂O₃ product.

1.4. Tetrasodium Phosphate

It is colorless, transparent, crystalline chemical compound with the formula Na₄P₂O₇. It is a salt composed of phosphate and sodium ions.

2. Basic Material Tests

| Test | Description | Weight (gm) |
|------|-------------|-------------|
| 1. | Weight of empty bottle (W₁) | 34 |
| 2. | Weight of bottle + cement (W₂) | 103 |
| 3. | Weight of bottle + cement + kerosene (W₃) | 179 |
| 4. | Weight of bottle + Kerosene (W₄) | 132 |

Specific gravity of cement

\[
\text{Specific gravity of cement} = \frac{(W₂-W₁)}{(W₂-W₁) - (W₃-W₄)} = \frac{5}{1.72}
\]

Specific gravity of coarse aggregate = 2.82

Table 3: Tested Results of Specific Gravity of Coarse Aggregate

| DESCRIPTION | Weight (kg) |
|-------------|-------------|
| weight of empty basket (W₁) | 2.57 |
| Weight of basket + coarse aggregate (W₂) | 7.57 |
| Weight of basket + coarse aggregate + water, (W₃) | 4.24 |
| Weight of basket + water, (W₄) | 2.48 |
| Weight of coarse aggregate in basket, (W₂-W₁) | 5 |
| Weight of equal volume of water (W₂-W₁) – (W₃-W₄) | 1.72 |

Table 4: Replacement percentage of fine aggregate

| Replacement % of Clay Content with FA | Mix Design |
|--------------------------------------|------------|
| For conventional concrete | 1:1.493:3.183 |
| 5% of partially replacement of F.A | 1:1.48:3.183 |
| 10% of partially replacement of F.A | 1:1.497:3.183 |
| 15% of partially replacement of F.A | 1:1.5:3.183 |

3. Selection of Clay and Soil

3.1 Swelling Index

Sample from PSNA CET

Volume of clay in water = 19 ml
Volume of clay in kerosene = 18 ml
\[ V_d = \text{volume of clay in water} \]
\[ V_k = \text{volume of clay in kerosene} \]

Swelling index = \( V_d - V_k \times 100\% = 5.55\% \)

Table 5: Swelling Limits (IS 2720 Part- 40 & 41) 1997

| S. No | Swelling limits in % |
|-------|----------------------|
| 1     | 0 – 15               |
| 2     | 10 – 35              |
| 3     | 20 – 55              |
| 4     | 35 above             |

3.2. EDAX results for clay

![Diagram of Swelling Index test]
3.3. EDAX results for soil

1) Silica content = 69.97%
2) Iron content = 8%

Table 6: Chemical Properties Tabulation

| Elements | An | Percentage Of Elements |
|----------|----|------------------------|
| O        | 8  | 57.75                  |

| 1.18            | 357.00                | 565.00                        | 208.00                   | 74.10  |
| 0.60 µ          | 340.00                | 562.50                        | 222.50                   | 48.24  |
| 0.30 µ          | 369.00                | 712.50                        | 343.50                   | 82.59  |
| 0.15 µ          | 319.00                | 397.00                        | 78.00                    | 17.41  |
| 0.75 µ          | 305.50                | 370.10                        | 64.60                    | 9.61   |
| Pan             | 328.50                | 354.00                        | 25.50                    | 0.60   |

Finess modulus = total sum of the cumulative % retained / 1000
= 496.27 / 1000
= 0.496

4. Calculations

4.1. For Compressive strength

\[
\text{Compressive strength} = \frac{\text{Load}}{\text{Area}}
\]

Load = 38000 * 9.81 = 372780 N.

\[
\text{Compressive strength} = \frac{\text{Load}}{\text{Area}} = \frac{372780}{22500} = 16.56 \text{ N/mm}^2
\]

4.2. For Split tensile strength

\[
\text{Split tensile strength} = \frac{2P}{\pi dl}
\]

\[
P = 21000 \times 9.81 = 206010 \text{ N.}
\]

\[
\text{Split tensile strength} = \frac{2P}{\pi dl} = \frac{412020}{141300} = 2.91 \text{ N/mm}^2
\]

5. Test Results

Table 10: Test results for cubes and cylinders

6. Conclusion

This study shows an alternative approach of replacing fine aggregate with clay particles in concrete. A comparative study of different percentage of clay particles to be replaced. Finally, it is concluded that, 1.5 % of decrease in Alumina powder and 1.5 % of increase in Sodium phosphate provides the value of conventional concrete. The EDAX results for all the cubes and cylinders are obtained to compare the compressive strength, split tensile strength results for both conventional and clay added concrete.
