General relativistic corrections to the galaxy power spectrum appearing at the horizon scale, if neglected, may induce biases on the measured values of the cosmological parameters. In this paper, we study the impact of general relativistic effects on non standard cosmologies such as scenarios with a time dependent dark energy equation of state, with a coupling between the dark energy and the dark matter fluids or with non–Gaussianities. We then explore whether general relativistic corrections affect future constraints on cosmological parameters in the case of a constant dark energy equation of state and of non–Gaussianities. We find that relativistic corrections on the power spectrum are not expected to affect the foreseen errors on the cosmological parameters nor to induce large biases on them.

PACS numbers:

I. INTRODUCTION

The complete general relativistic description of the observed matter power spectrum is, at large scales, significantly different from the standard Newtonian one. The observed redshift and position of galaxies are affected by matter fluctuations and gravity waves between the source and the observer, see e.g. Ref. [1]. In addition, the matter density perturbation, $\delta_m$, is gauge dependent while observable quantities, such as the power spectrum, should be gauge invariant. The standard picture looks, therefore, incomplete, and a general relativistic description is needed in order to correctly compute the measured observables $^2$ $^3$. Current observations, based on available galaxy surveys, are not affected, in practice, by general relativistic corrections since they appear only at very large scales. In future galaxy surveys, however, these corrections may interfere with the measure of other physical effects which modify the large-scale shape of the power spectrum.

In this paper, we study the general relativistic effects in several cosmological scenarios, like: i) a constant dark energy equation of state; ii) a time varying equation of state $w(a)$; iii) non–Gaussianities; iv) a coupling between dark energy and dark matter; and finally iv) massive neutrinos. For the scenarios i) and iii), we compute the expected errors and biases from a future Euclid-like galaxy survey by means of a Fisher matrix analysis, comparing the results with and without general relativistic corrections in the matter power spectrum.

The structure of the paper is the following. Section II summarizes the general relativistic corrections treatment. In Sec. III the impact of general relativistic corrections in the cosmological scenarios quoted above is presented. The expected errors and biases on the cosmological parameters are computed in Sec. IV for two particular scenarios. Finally in Sec. V we conclude.

II. PRELIMINARIES

Following the results of Refs. [1,2], we briefly summarize the treatment of the observed galaxy power spectrum in redshift space. In linear perturbation theory, the observed (matter) density $\rho_m$ at a given redshift is defined as a function of the density fluctuation $\delta_m$ and the background (matter) density $\bar{\rho}_m$

$$\rho_m = \bar{\rho}_m(\bar{\bar{z}})(1 + \delta_m).$$ (1)
For the standard ΛCDM cosmology, that we take as reference, the background matter density in terms of
the current Hubble parameter $H_0$ and today’s matter density relative to the critical density $\Omega_m$ reads $^1$: 

$$\bar{\rho}_m(\bar{z}) = \frac{3H_0^2}{8\pi G} \Omega_m(1 + \bar{z})^3.$$  \hspace{1cm} (2)

In Eqs. (1) and (2), the dependence of the background density $\bar{\rho}_m$ on the background redshift $\bar{z}$ has been made explicit. The ratio between the emitter and the observed frequencies at the background level is defined as

$$1 + \bar{z} = \frac{\bar{\nu}_e}{\bar{\nu}_o} = \frac{(\bar{K}^\mu \bar{u}_\mu)_e}{(\bar{K}^\mu \bar{u}_\mu)_o} = \frac{1}{\bar{a}},$$  \hspace{1cm} (3)

where $\bar{K}^\mu$ and $\bar{u}_\mu$ are the background photon wave vector and the background emitter/observer $(e/o)$ four-
velocity, respectively. At linear order in perturbation theory, the observed redshift of a given source, $z$, differs from the background one due to the matter/gravity fluctuations that the photon encounters between the emitter and the observer positions. The perturbed four-velocity and photon null–vector read:

$$u^\mu = \frac{1}{\bar{a}} \left( 1 - A, v^i \right);$$  \hspace{1cm} (4)

$$K^\mu = \frac{\bar{\nu}}{\bar{a}} \left( 1 + \frac{\delta \nu}{\bar{\nu}}, n^i + \delta n_i \right),$$  \hspace{1cm} (5)

where $\mu = 0, \ldots, 3$ and $i = 1, \ldots, 3$. $v^i$ is the peculiar velocity of the observer/emitter and $\delta \nu$ and $\delta n_i$ are the perturbed photon frequency and propagation direction, respectively. The conventions used for the perturbed Friedmann-Robertson-Walker (FRW) metric, together with a list of useful relations, can be found in Appendix A. The observed (perturbed) redshift $z$ thus reads:

$$1 + z \equiv 1 + \bar{z} + \delta z = \frac{(K^\mu u_\mu)_e}{(K^\mu u_\mu)_o} = \frac{1 + \frac{\delta \nu}{\bar{\nu}}}{\bar{a} + (B_i - v_i) n^i} \left[ 1 + \frac{\delta \nu}{\bar{\nu}} + A + (B_i - v_i) n^i \right].$$  \hspace{1cm} (6)

Expressing the matter density in terms of the observed redshift, instead of the unobservable background one, it gives:

$$\rho_m = \bar{\rho}_m(z) \left( 1 + \delta_m - \frac{d\bar{\rho}_m}{dz} \frac{\delta z}{\bar{\rho}_m} \right) = \bar{\rho}_m(z)(1 + \Delta z),$$  \hspace{1cm} (7)

with the background matter density $\bar{\rho}_m(z)$ function of the observed redshift $z$. While the density contrast $\delta_m$ and the redshift fluctuation $\delta z$ are gauge dependent quantities, their combination $\Delta z$ is, instead, gauge invariant. Notice, however, that the truly observed quantity is the galaxy number density perturbation $^2, ^4, ^5$, corresponding to:

$$\Delta_{obs} = \frac{\delta N}{N} \equiv \frac{N(z) - \bar{N}(z)}{\bar{N}(z)} = \Delta z + \frac{\delta \text{Vol}}{\text{Vol}},$$  \hspace{1cm} (8)

where an extra contribution from the physical survey volume perturbation appears. Being the volume density perturbation, $\delta \text{Vol}$, a gauge invariant quantity, $\Delta_{obs}$ is automatically gauge invariant, as it should be for any observable quantity. In addition, one has to introduce a bias between galaxy and matter overdensities. We will ignore for the moment the bias issue, deferring a brief discussion of this aspect to Sec. III B.

Making use of the null energy condition and the photon geodesic equation (see Appendix A and also Refs. $^1, ^2, ^3$ for more details) one can write $\Delta z$ in terms of gauge invariant quantities as:

$$\Delta z = \Delta_m + 3 \mathbf{n} \cdot \mathbf{V} + 3 (\Psi_B - \Phi_B) - 3 \int_{\lambda_o}^{\lambda_e} d\lambda \left( \dot{\Psi}_B - \dot{\Phi}_B \right),$$  \hspace{1cm} (9)

$^1$ See Sec. III C for non standard cosmologies in which Eq. (2) is not valid.
where $\Phi_B$ and $\Psi_B$ are the Bardeen potentials and $\Delta_m$ and $V$ are the gauge invariant matter density contrast and peculiar velocity, which definitions can be found in Appendix A. The last term in Eq. (9) is the usual integrated Sachs–Wolfe effect between the observer and the emission point with $d/d\tau = \partial_x + n^i\partial_i$. The survey volume perturbation $\delta \text{Vol}$ has been carefully derived in several references, see e.g. Refs. [2, 4], we therefore omit the details of its calculation here. Neglecting the unmeasurable monopole and dipole perturbations at the observer position, the expression of $\Delta_{\text{obs}}$ in terms of gauge invariant quantities reads:

$$
\Delta_{\text{obs}} = \Delta_m + \Phi_B - \Phi_B - n \cdot V - \frac{1}{H} \left[ n^i \partial_i \Phi_B + \frac{d}{d\lambda} (n \cdot V) \right] + \left( \frac{2}{r_s H} + \frac{\dot{H}}{H^2} \right) \left[ n \cdot V + \Psi_B + \int_0^{r_s} d\lambda \left( \dot{\Phi}_B - \Phi_B \right) \right] + \frac{2}{r_s} \int_0^{r_s} d\lambda (\Psi_B - \Phi_B) - \frac{1}{r_s} \int_0^{r_s} d\lambda \frac{r_s - r}{r} \Delta_\Omega (\Psi_B - \Phi_B) ,
$$

(10)

where $r_s = \int_{\tau_0}^{\tau_s} d\tau$ corresponds to the comoving distance between the source and the observer and $\Delta_\Omega$ is the angular Laplacian on a unit sphere. Notice that Eq. (10) holds for the standard cosmology case and reduces to Eq. (30) of Ref. [4] once the Euler equation for the gauge invariant matter velocity scalar perturbation:

$${\dot{V}^i} = -H V^i - \partial_x I_B ,$$

(11)

is implemented. Also, let us emphasize that we have assumed a constant comoving source number density and ignored the vector and tensor contributions in Eqs. (9) and (10).

For later convenience, let us express Eqs. (9) and (10) in the Newtonian gauge. The density perturbations $\Delta_\tau$ and $\Delta_{\text{obs}}$ read respectively:

$$
\Delta_\tau = \delta_m^N + 3 n \cdot v + 3 \Psi_N - 3 \int d\lambda (\Psi_N + \dot{\Phi}_N) ;
$$

(12)

$$
\Delta_{\text{obs}} = \delta_m^N + \frac{1}{H} n \cdot \partial_x v - 2 \kappa + \Psi_N - 2 \dot{\Phi}_N + \frac{1}{H} \dot{\Phi}_N + \left( \frac{2}{r_s H} + \frac{\dot{H}}{H^2} \right) \left[ n \cdot V + \Psi_N + \int_0^{r_s} d\lambda \left( \dot{\Phi}_N + \dot{\Phi}_N \right) \right] + \frac{2}{r_s} \int_0^{r_s} d\lambda (\Psi_N + \dot{\Phi}_N) ,
$$

(13)

where $\kappa$ is the lensing convergence (see Eq. A10), $\Psi_N$ and $\Phi_N$ are the scalar perturbations of the metric in the Newtonian gauge (see Appendix A) and the partial derivative $\partial_x = e^i \partial_i = -n^i \partial_i$ with $e^i$ indicating the source position. With $\delta_m^N$ and $v$, we refer to the matter density and peculiar velocity perturbation in the Newtonian gauge.

In the standard Newtonian approximation, the galaxy number density perturbation, $\Delta_\tau$, only gets contributions from the three first terms of Eq. (13), namely from the matter density perturbation, the redshift space distortion term and from the convergence term. We consider that, neglecting the bias between galaxy and matter overdensities, the associated standard Newtonian power spectrum is related to the matter power spectrum evaluated in the synchronous gauge$^2$ in the following way:

$$
P_{\Delta_\tau} = P_m^S (1 + f_{\text{eff}} \mu_k^2) ^2 .
$$

(14)

The latter is typically used for calculating the power spectrum when relativistic contributions can be safely neglected (i.e. for scales much smaller than the horizon scale). In Eq. (14), the index $S$ refers to the synchronous comoving gauge, $f_{\text{eff}}$ is the linear growth function and $\mu_k$ is the cosine of the angle between the line of sight and the wave vector $k$. In standard cosmological scenarios, the growth function $f_{\text{eff}}$ is given by $d \ln \delta_m / d \ln a$.

Notice that in Eq. (14) we have ignored the contribution from the convergence term. Through all this study contributions from projected quantities have been neglected when computing the 3-D power spectrum.

$^2$ For a comprehensive discussion see for example Refs. [5, 6].

III. COSMOLOGICAL SCENARIOS

We explore below the impact of general relativistic corrections in several cosmological scenarios which include the presence of a constant dark energy equation of state and the presence of non–Gaussianities. In the next section, we will estimate the foreseen errors on the several cosmological parameters involved in each of these two cosmologies using the Fisher matrix formalism. For the sake of illustration, we also discuss the effect of general relativistic corrections on the observed galaxy power spectrum in the case of a time varying equation of state $w(a)$, a coupling between dark energy and dark matter and massive neutrinos.

Unless otherwise stated, the following numerical values for the cosmological parameters have been used: $\Omega_b h^2 = 0.02267$, $\Omega_{\text{dm}} h^2 = 0.1131$, $h = 0.705$, the scalar amplitude $A_s = 2.64 \times 10^{-9}$ and the scalar spectral index $n_s = 0.96$. $\Omega_{\text{b}}(\text{dm})$ refers to the current baryon (dark matter) energy density relative to the critical density and $h$ is related to the present value of the Hubble parameter $H_0 = 100h$ Mpc/km/s. The sound speed for the dark energy fluid is fixed to $c_s^2 = 1$.

A. Dark energy

We first consider a cosmological model including standard cold dark matter and a dark energy fluid characterized by a constant equation of state $w$. Figure 1 shows the dark matter power spectra $P_{\Delta v}(k, \mu_k)$ and $P_{\Delta t}(k, \mu_k)$ for both the line-of-sight ($\mu_k = 1$) and the transverse ($\mu_k = 0$) modes at $z = 0.5$ for several values of $w$, ranging from $w = -0.9$ to $w = -0.5$. The horizon scale, $k_H$ is also shown for the $w = -0.9$ case.

\footnote{We know that luminous red galaxies occupy massive dark matter halos today from weak lensing measurements \cite{7}.}
FIG. 2: $P_{\Delta_{\text{obs}}}(k)$ (solid lines) and $P_{\Delta_{\text{st}}}(k)$ (dashed lines) for $\mu_k = 1$ (left panel) and $\mu_k = 0$ (right panel) for the three possible $w(a)$ cosmologies explored here at $z = 0.5$. The vertical lines depict the horizon scale $k_H$ for $w_0 = -1$ and $w_a = 0$.

Notice that, in Sec. [II], we discuss the $k$ position of the dip appearing at large scales in the power spectrum $P_{\Delta_{\text{obs}}}(k, \mu_k)$ in the transverse direction (right plot). The modifications in the shape of the power spectra when relativistic effects are considered barely change when the dark energy equation of state is varied. In addition, the new features on the power spectrum induced by the general relativity terms barely change when the dark energy equation of state is varied. Therefore, the extra information contained in these general relativistic terms will poorly increase the precision on the measurement of a time varying dark energy equation of state.

B. Non–Gaussianity

In this section, we take into account a non zero bias between galaxy and dark matter overdensities. Following the prescription of several recent studies [5, 6, 16] and considering a linear bias relation in the comoving synchronous gauge, the galaxy and dark matter overdensities are related by $\delta_g = b \delta_{\text{dm}}$. If the primordial fluctuations are Gaussian, it is generally assumed that this bias $b$ is scale independent.

Deviations from Gaussian initial conditions offer a unique tool for testing the mechanism which generated primordial perturbations. Non–Gaussianities are commonly characterized by a single parameter, $f_{\text{NL}}$. The local primordial Bardeen gauge-invariant potential on large scales in the matter dominated era can be written...
as \(17\text{–}20\)

\[
\Phi_{\text{NG}} = \Phi_G + f_{\text{NL}} \left( \Phi_G^2 - \langle \Phi_G^2 \rangle \right) ,
\]

(15)

where \(\Phi_G\) is a Gaussian random field. The non–Gaussianity parameter \(f_{\text{NL}}\) is often considered to be a constant, yielding non–Gaussianities of the local type with a bispectrum which is maximized for squeezed configurations \(21\). The standard observables to constrain non–Gaussianities are the CMB and the Large-Scale Structure (LSS) of the Universe. References \(22\) and \(23\) showed that primordial non–Gaussianities affect the clustering of dark matter halos inducing a scale-dependent large-scale bias \(24\text{–}30\).

Following Refs. \(22, 24, 31\) (see also \(6, 16, 32\) for recent studies with general relativity corrections), we consider a scale dependent bias induced by the local non–Gaussianity of the following form

\[
\delta^S_g = b \delta^S_{\text{dm}} \quad \text{where} \quad b = b_G + \Delta b ,
\]

(16)

with \(b_G\), a constant Gaussian bias and

\[
\Delta b = 3f_{\text{NL}}(1 - b_G)\frac{H_0^2 \Omega_m}{k^2 T(k)D(a)} .
\]

(17)

\(T(k)\) is the linear transfer function that we have taken to be equal to unity and \(D(a)\) is the growth factor defined as \(\delta_{\text{dm}}(a)/\delta_{\text{dm}}(a = 1)\). The linear overdensity for spherical collapse can be considered as a constant: \(\delta_c = 1.686\) \(33\).

The resulting non Gaussian halo power spectrum is shown in Fig. 3. The standard Newtonian power spectrum is now obtained using

\[
P_{\Delta \ell} = P_{\text{dm}}^S \left( b_G + \Delta b + f_{\text{eff}} \mu_k^2 \right)^2 ,
\]

(18)

while the general relativity-corrected power spectra is obtained expressing Eq. (10) in the synchronous gauge and replacing \(\delta_n\) by the galaxy density fluctuation defined in Eq. (16). The left (right) panel of Fig. 3 shows the power spectra for the line of sight (transverse) modes. Note that even in the absence of general relativity corrections the introduction of a negative \(f_{\text{NL}}\) induces the presence of a dip at large scales (contrarily to the case of positive \(f_{\text{NL}}\)). This can be easily understood by studying the \(k\) dependence of the factor multiplying \(P_{\text{dm}}^S\) in Eq. (18). In the negative \(f_{\text{NL}}\) case, once we introduce general relativity corrections, the dip at large scales can become shallower (deeper) in the \(\mu_k = 1\) (\(\mu_k = 0\)) case. In the case of the positive \(f_{\text{NL}}\) values considered here, the presence of non Gaussianities induces an increase of the Newtonian matter power spectrum at \(k < 0.01\) Mpc/\(h\). General relativity corrections may also induce an increase of the power spectrum but at larger scales, \(k < 0.001\) Mpc/\(h\). However, non–Gaussianities dominate the shape of the power spectrum and make the general relativity effects totally subdominant. The shape of the non–Gaussian power spectrum rarely changes when general relativistic effects are considered, regardless of the sign of the non Gaussianity parameter \(f_{\text{NL}}\). Therefore, we do not expect an important improvement on the precision measurement of the different cosmological parameters nor large biases on them in a non–Gaussianity scenario when general relativity corrections are included, see Sec. IV for a quantitative analysis.

C. Coupled and modified gravity cosmologies

Interactions within the dark sectors, i.e. between cold dark matter and dark energy, are still allowed by observations \(34\text{–}51\). Constraints on coupled cosmologies as well as on modified gravity models could also be affected by the relativistic effects on the matter power spectrum. As an illustration, we parameterize the dark matter-dark energy interactions at the level of the stress-energy tensor conservation equations. Following the notations of \(47\), an energy momentum exchange of the following form can be introduced:

\[
\nabla^\mu T^\nu_{(\text{dm})\nu} = Q_\nu \quad \text{and} \quad \nabla^\mu T^\nu_{(\text{de})\nu} = -Q_\nu ,
\]

(19)

with

\[
Q_\nu = \xi \mathcal{H} \rho_{\text{de}} u^\nu_{\nu} / a \quad \text{or} \quad Q_\nu = \xi \mathcal{H} \rho_{\text{de}} u^\nu_{(\text{de})\nu} / a ,
\]

(20)
where $u_{\nu}^{\text{dm}(\text{de})}$ is the cold dark matter (dark energy) four velocity and $\xi$ is a dimensionless coupling, considered negative in order to avoid early time non adiabatic instabilities. In general, coupled models with $Q_\nu$ proportional to $u_{\nu}^{\text{de}}$ are effectively modified gravity models. Assuming a flat universe and perfect measurements of $\Omega_{\text{dm}} h^2$, $\Omega_b h^2$, and of the angular diameter distance to the last scattering surface from Cosmic Microwave Background (CMB) observations, the amplitude of $\xi$ is degenerate with the physical energy density in dark matter today, $\Omega_{\text{dm}} h^2$. Consequently, $\Omega_{\text{dm}} h^2$ should be changed accordingly each time $\xi$ is varied, see Appendix B of Ref. [48] for the values of $\Omega_{\text{dm}} h^2$ and $h$ considered here.

Coupled cosmologies imply some extra terms in the expression of the gauge invariant matter fluctuation Eq. (9). Indeed, in the case of the coupled models studied here

$$\frac{d\rho_{\text{dm}}}{dz} = 3 \frac{\rho_{\text{dm}}}{1+z} - \xi \frac{\rho_{\text{de}}}{1+z},$$

which directly affects the expressions for $\Delta_m$ and $\Delta_z$. In the $u_{\nu}^{\text{dm}}$ case the gauge invariant quantity defined in Eq. (7) becomes:

$$\Delta z^{u_{\nu}^{\text{dm}}} = \Delta z^{\xi} + \left(3 - \xi \frac{\rho_{\text{de}}}{\rho_{\text{dm}}} \right) \left[ n \cdot V_{\text{dm}} + (\Psi_B - \Phi_B) + \int_0^r d\lambda \left( \dot{\Psi}_B - \dot{\Phi}_B \right) \right],$$

where we have made explicit the $\xi$ dependence of the gauge invariant dark matter density perturbation:

$$\Delta z^{\xi} = \delta_{\text{dm}} + (3 - \xi \rho_{\text{de}}/\rho_{\text{dm}}) \mathcal{R}/H,$$

where $\mathcal{R}$ is the curvature perturbation defined in Eq. (A5). In the $u_{\nu}^{\text{de}}$ case another extra contribution results from the modified Euler equation. In the gauge invariant formalism for dark matter perturbations (see e.g. [47])

$$\dot{V}_{\text{dm}} = -H V_{\text{dm}} - \nabla \Psi_B + \xi \frac{\rho_{\text{de}}}{\rho_{\text{dm}}} \mathcal{H} (V_{\text{de}} - V_{\text{dm}}).$$

Therefore, the perturbation in the number density of galaxies in the $u_{\nu}^{\text{de}}$ case reads

$$\Delta z^{u_{\nu}^{\text{de}}} = \Delta z^{u_{\nu}^{\text{dm}}} - \xi \frac{\rho_{\text{de}}}{\rho_{\text{dm}}} (V_{\text{de}} - V_{\text{dm}}) \cdot n.$$
Power spectrum $[h^{-3} \text{Mpc}^3]$ $k$ [Mpc/h]

Power spectra at redshift $z=0.50$ for $\mu_k=1$ $\xi=-0.0$ $\xi=-0.1$ $\xi=-0.2$ $\xi=-0.3$ $\xi=-0.4$ $k H$

Power spectra at redshift $z=0.50$ for $\mu_k=0$ $\xi=-0.0$ $\xi=-0.1$ $\xi=-0.2$ $\xi=-0.3$ $\xi=-0.4$ $k H$

**FIG. 4:** The left (right) panel depicts $P_{\Delta_{\text{obs}}}(k)$ and $P_{\Delta_{\text{st}}}(k)$ by solid and dashed lines, respectively for coupled models $\propto u_{\text{dm}}^\nu$ and $\mu_k=1$ ($\mu_k=0$). Different values of the coupling $\xi$ are illustrated, and the redshift is $z=0.5$. In all the models, the cosmological parameters $\Omega_{\text{dm}} h^2$ and $h$ have been chosen to satisfy CMB constraints. The vertical lines show the horizon scale for $w = -0.9$.

Figure 4 depicts the resulting matter power spectra $P_{\Delta_{\text{obs}}}(k,\mu_k)$ and $P_{\Delta_{\text{st}}}(k,\mu_k)$ for coupled models with an interaction term proportional to $u_{\text{dm}}^\nu$ for both the line of sight and transverse modes at $z=0.5$ and for different values of the coupling $\xi$. Notice that in coupled cosmological scenarios considered here, the growth function appearing in the definition of $P_{\Delta_{\text{st}}}(k,\mu_k)$ in Eq. (14) is given by $d \ln \delta_{\text{dm}}/d \ln a + \xi \rho_{\text{de}}/\rho_{\text{dm}}$ [48]. Similar results are obtained for the case in which the coupling term is proportional to $u_{\text{de}}^\nu$. As in the case of the dark energy equation of state, no strong biases are expected in constraining the coupling when these new general relativistic terms are included in the analysis: the shape of the different curves including relativistic corrections barely changes when the coupling is varied.

### D. Neutrino masses

Consider a $\Lambda$CDM model plus massive neutrinos of a given energy density $\Omega_{\nu} h^2$. We would like to determine if the massive neutrino energy density could affect the position of the dip appearing in the dark matter power spectrum $P_{\Delta_{\text{obs}}}(k,\mu_k)$ for the transverse modes ($\mu_k=0$). In order to simplify the discussion let us consider the expression of $\Delta_{\text{obs}}$ in the Newtonian gauge, see Eq. (13). In the approximation in which all projected quantities in the power spectrum computation are neglected, the dip appears for $\mu_k=0$ (i.e. $\mathbf{n} \cdot \mathbf{v} = 0$) when the condition

$$\delta_{\text{dm}}^N + \Psi_N - 2 \Phi_N + \frac{1}{H} \dot{\Phi}_N + \left( \frac{2}{r_s H} + \frac{\dot{H}}{H^2} \right) \Psi_N = 0$$

is satisfied. For a specific choice of redshift and of cosmology, the factor $\Sigma = (2/(r_s H) + \dot{H}/H^2)$ does not depend on the wave number $k$. Neglecting anisotropic stress, so that $\Psi_N = \Phi_N$, and making use of the Einstein equations (see Ref. [52] for the prescription used here):

$$k^2 \Psi_N = -\frac{3}{2} H^2 \sum_a \Omega_a \left( \delta_a^N + \frac{3 H}{k} (1 + w_a) v_a \right),$$

$$k^2 (\Phi_N + H \Psi_N) = \frac{3}{2} H^2 \sum_a \Omega_a (1 + w_a) k v_a,$$
the dip position in the Fourier space as a function of $\Omega_\alpha, \delta_\alpha, v_\alpha$ can be extracted:

$$k^2 = \frac{3}{2\delta_{\text{dm}}} \mathcal{H}^2 \sum_\alpha \Omega_\alpha \left[ (\Sigma - 2) \delta_\alpha + (w_\alpha + 1) v_\alpha \left( 3 \frac{\mathcal{H}}{k} (\Sigma - 2) - \frac{k}{\mathcal{H}} \right) \right].$$ (29)

In the previous equations the index $\alpha$ runs over all the relevant fluids. In principle, different scenarios with different $\Omega_\alpha$ will show a dip at different wave numbers. However, this $k$ difference will vanish when the total matter energy density (i.e. cold dark matter plus baryons plus the neutrino contribution) is kept constant. Therefore, general relativity effects can not help in extracting the values of the neutrino masses.

IV. COSMOLOGICAL PARAMETER FORECASTS AND BIASES

In this section we explore if the measurement of the different cosmological parameters is affected by relativistic corrections. We present constraints from future galaxy survey measurements, making use of the Fisher matrix formalism. Then, we compare the cosmological parameter errors with and without general relativistic corrections.

A. Methodology

The Fisher matrix is defined as the expectation value of the second derivative of the likelihood surface about the maximum. As long as the posterior distribution for the parameters is well approximated by a multivariate Gaussian function, its elements are given by [53–55]

$$F_{\alpha\beta} = \frac{1}{2} \text{Tr} \left[ C^{-1} C_{,\alpha} C^{-1} C_{,\beta} \right],$$ (30)

where $C = S + N$ is the total covariance which consists of signal $S$ and noise $N$ terms. The commas in Eq. (30) denote derivatives with respect to the cosmological parameters within the assumed fiducial cosmology. The 1–σ error on a given parameter $p_\alpha$ marginalized over the other parameters is $\sigma(p_\alpha) = \sqrt{(F^{-1})_{\alpha\alpha}}$, $F^{-1}$ being the inverse of the Fisher matrix. In order to focus on the role played by general relativity corrections, we have restricted the analysis to galaxy survey data, i.e. we have not included in the analysis forecasts from the on going Planck CMB experiment. We exploit here an enlarged version of the future Euclid galaxy survey experiment, with an area of 20000 deg$^2$, 24 redshift slices between $z = 0.15$ and $z = 2.55$ and a mean galaxy density of 1.56 $\times$ 10$^{-3}$, see Refs. [56, 57].

Two possible fiducial cosmologies are analyzed: i) a constant $w$ cosmology ($w$ denotes the dark energy equation of state), and ii) a constant $w$ cosmology with the presence of primordial non Gaussianities (characterized by the parameter $f_{\text{NL}}$). In the analysis i), the model is described by the physical baryon and cold dark matter densities, $\Omega_b h^2$ and $\Omega_{\text{dm}} h^2$, the scalar spectral index, $n_s$, $h$, the dimensionless amplitude of the primordial curvature perturbations, $A_s$ and $w$. In the analysis ii), which includes non–Gaussianities, the model is described by $\Omega_b h^2$, $\Omega_{\text{dm}} h^2$, $h$, $w$, the dark energy sound speed squared $c_s^2$ and the $f_{\text{NL}}$ parameter. We have therefore fixed in this case the scalar spectral index and the dimensionless amplitude of primordial fluctuations, expected to be measured with excellent accuracy by the CMB Planck experiment. We follow a conservative approach, assuming that non–Gaussianities are constrained exclusively from the very large scale halo power spectrum.

In addition to the marginalized parameter errors, the biases induced in the cosmological parameters when data are wrongly fitted to the standard Newtonian power spectrum, neglecting general relativity corrections, are also computed. The biases in the cosmological parameters read [58]

$$\delta p_\alpha = (F^{-1})_{\alpha\beta} \sum_i \frac{\partial \mathcal{O}_{\text{obs}}^i}{\partial p_\beta} \frac{1}{\sigma_{\mathcal{O}_{\text{obs}}^i}^2} \left( \mathcal{O}_{\text{obs}}^i - \mathcal{O}_{\text{st}}^i \right),$$ (31)

where the sum runs over the bins indices in $i = z, k$ and $\mu_k$ in the case of the 3-D power spectrum analysis, i.e. $\mathcal{O} = P(z, k, \mu_k)$, and $i = z$ and $\ell$ in the case of the 2-D power spectrum analysis , i.e. $\mathcal{O} = C_\ell(z)$. $F$ is the Fisher matrix computed with the power spectra including general relativity corrections, $\mathcal{O}_{\text{obs}}^{i(k,z)}$ and
$C^{k,z}_{\ell}$ are the general relativity and standard Newtonian power spectra respectively and $\sigma_{C^{k,z}}$ is the error on the power spectrum with general relativity corrections.

In the case of analysis ii), we also have determined the shifts in the parameters $\{\Omega_b h^2, \Omega_{dm} h^2, h, w, \sigma_8^2\}$ that would result when mock data generated with primordial non-Gaussianities ($f_{NL} = 20$ in this example) are fitted to a theoretical model without them. The idea is the following: if the data are fitted assuming a model $M_1$ with $n_1$ parameters, but the true underlying cosmology is a model $M_2$ characterized by $n_2$ parameters (with $n_2 > n_1$ and the parameter space of $M_2$ includes the model $M_1$ as a subset), the inferred values of the $n_1$ parameters will be shifted from their true values to compensate for the fact that the model used to fit the data is wrong. In the case illustrated here, $M_2$ will be the model with non-Gaussianities and $M_1$ the one without non-Gaussianities, i.e., with $f_{NL} = 0$. While the first $n_1$ parameters are the same for both models, the remaining $n_2 - n_1$ parameters in the enlarged model $M_2$ are accounting for the presence of non-Gaussianities, i.e., $f_{NL}$. Assuming a Gaussian likelihood, the shifts of the remaining $n_1$ parameters are given by [31]:

$$\delta \theta' = -(G^{-1})_{\alpha\beta} F_{\beta\zeta} \delta \psi_{\zeta}$$

where $G$ represents the Fisher sub-matrix for the model $M_1$ and $F$ denotes the Fisher matrix for the model $M_2$. In the case considered in this paper, $M_1$ is the model without primordial non-Gaussianities while $f_{NL} \neq 0$ in the model $M_2$ so that $n_2 - n_1 = 1$ and $\delta \psi = \delta f_{NL} = 20$.

### B. 3-D Power Spectrum

For details regarding the calculation of the Fisher matrix for the 3-D power spectra $P(k; \mu_k)$ measured by a galaxy survey, see Ref. [60]. Here we perform a binning both in $k$ and in $\mu_k$, considering nine bins in the former quantity. The minimum scale $k_{\text{min}}$ is fixed to $10^{-4} h/\text{Mpc}$ and the maximum scale is fixed to 0.1 $h/\text{Mpc}$.

Table I contains the 1-σ marginalized errors on the cosmological parameters for analysis i), with a fiducial cosmology with constant dark energy equation of state $w = -1$. Two results are illustrated: those obtained with the standard Newtonian power spectrum and those obtained with general relativistic corrections included. Note that the errors obtained in the standard Newtonian prescription are generally 40% smaller than those obtained with general relativistic one, except for the $w$ parameter in which case the tendency is reversed. The biases on the cosmological parameters are also presented in Tab. I. Note that their size is always smaller than the 1-σ marginalized errors and therefore these biases will barely interfere with the extraction of the cosmological parameters.

Table II presents the results from analysis ii), which includes non-Gaussianities with a fiducial $f_{NL} = 20$. Recently, the authors of Ref. [32] have shown that using methods to reduce the sampling variance and shot noise [61, 62], a full sky galaxy survey can measure general relativistic effects. We do not exploit here these cancellation methods, leaving these combined techniques for a future study.

The errors on cosmological parameters resulting from the Fisher analysis are not improved including general relativity corrections. This fact was not unexpected, given that for the value of the $f_{NL}$ considered in this analysis the changes in the power spectrum due to general relativity corrections are almost hidden by the effect of non-Gaussianities, see Sec. III.B. Note also that the biases are always smaller than the corresponding 1-σ marginalized errors and therefore they will have no impact on the extraction of the cosmological parameters. Also, we find no significant shifts in the values of the cosmological parameters in any of the two prescriptions when the non-Gaussianity parameter $f_{NL}$ is (wrongly) assumed to be zero. We conclude that relativistic corrections in the 3-D power spectrum will not help in constraining the cosmological parameters.

Finally, we briefly comment on the dependence of the cosmological parameter errors on the maximum scale considered in the analysis, $k_{\text{max}}$, assuming a fiducial cosmology with a constant dark energy equation of state $w = -1$. A larger $k_{\text{max}}$ will imply a larger number of modes, more information from the location of the acoustic peaks is available and consequently the errors will be smaller. Figure 5 illustrates the size of the relative errors on the different cosmological parameters considered in analysis i) versus the scale $k_{\text{max}}$. Going from $k_{\text{max}} = 0.05 h/\text{Mpc}$ to $k_{\text{max}} = 0.2 h/\text{Mpc}$ the expected errors in $\Omega_b h^2, \Omega_{dm} h^2, h$ and $w$ are reduced by a factor $\sim 5$ while in the case of the $n_s$ parameter its error is reduced one order of magnitude.
| Parameter        | $P_{\Delta s}(k, \mu_k)$ | $P_{\Delta obs}(k, \mu_k)$ | Biases                        |
|------------------|---------------------------|-----------------------------|-------------------------------|
| $\Delta(\Omega_{dm}h^2)$ | 0.0035                    | 0.0057                      | $7.0 \times 10^{-5}$          |
| $\Delta(\Omega_b h^2)$   | 0.0010                    | 0.0016                      | $-8.0 \times 10^{-5}$         |
| $\Delta A_s$         | 0.021                     | 0.036                       | $1.1 \times 10^{-5}$          |
| $\Delta h$           | 0.010                     | 0.017                       | $1.3 \times 10^{-4}$          |
| $\Delta n_s$         | 0.012                     | 0.016                       | $-4.3 \times 10^{-3}$         |
| $\Delta w$           | 0.015                     | 0.010                       | $7.7 \times 10^{-3}$          |

TABLE I: $1-\sigma$ marginalized errors from the Euclid-like survey considered here for a fiducial cosmology with a constant dark energy equation of state, with a fiducial value $w = -1$. The third row illustrates the biases induced in the cosmological parameters when general relativistic corrections are (wrongly) neglected. The error on the amplitude of the primordial fluctuations $\Delta A_s$ is quoted in units of $2.64 \times 10^{-9}$.

| Parameter        | $P_{\Delta s}(k, \mu_k)$ | $P_{\Delta obs}(k, \mu_k)$ | Biases          | Shifts            |
|------------------|---------------------------|-----------------------------|-----------------|-------------------|
| $\Delta(\Omega_{dm}h^2)$ | 6.2 $10^{-4}$             | 6.1 $10^{-4}$              | $-4.8 \times 10^{-5}$ | $-2.4 \times 10^{-4}$ |
| $\Delta(\Omega_b h^2)$   | 8.7 $10^{-4}$             | 9.3 $10^{-4}$              | $-6.3 \times 10^{-5}$ | $3.4 \times 10^{-4}$ |
| $\Delta h$           | 3.5 $10^{-3}$             | 3.8 $10^{-3}$              | $-3.5 \times 10^{-4}$ | $2.0 \times 10^{-3}$ |
| $\Delta n_s$         | 1.310$^{-2}$              | 2.0 $10^{-3}$              | $-3.5 \times 10^{-3}$ | $1.5 \times 10^{-2}$ |
| $\Delta c_s^2$       | 4.0                       | 4.3                        | 1.0             | -2.5              |
| $\Delta f_{NL}$      | 3.1                       | 3.1                        | 0.7             | -                 |

TABLE II: $1-\sigma$ marginalized errors from the Euclid-like survey considered here for a fiducial cosmology with a constant dark energy equation of state, with fiducial values $w = -1$, $f_{NL} = 20$ and $c_s^2 = 1$. The third row presents the biases induced in the cosmological parameters when general relativistic corrections are neglected. The shifts in the cosmological parameters when $f_{NL}$ is set to zero but the data are generated with $f_{NL} = 20$ have been computed including general relativity corrections. Similar results are obtained using the standard Newtonian expression.

FIG. 5: Illustration of the relative $1-\sigma$ marginalized errors ($\Delta p/p$) dependence on the scale $k_{\text{max}}$ using the standard Newtonian prescription for the cosmological parameters $p = \Omega_b h^2, \Omega_{dm}h^2, h, w, A_s$ and $n_s$ for a fiducial cosmology with a constant dark energy equation of state with a fiducial value $w = -1$. 
C. 2-D Angular Power Spectrum

The 2-D $C_\ell$ angular power spectrum is a projection of the 3-D quantity and therefore it implies an integration of the 3-D power spectrum $P(k)$ convoluted with a window function, the Bessel transform of the radial selection function, see Refs. 64, 65. Therefore, the $C_\ell$'s are not expected to give as much information on the cosmological parameters as the 3-D power spectrum $P(k)$. For the calculations presented here we have computed the $C_\ell$ assuming no magnification bias and a constant distribution of sources with redshift. For details regarding the calculation of the Fisher matrix for the 2-D power spectra measured by a galaxy survey, see Ref. 66 (notice that we considered $\ell_{\text{min}} = 2$ and $\ell_{\text{max}} = 400$).

Table III contains the 1-σ marginalized errors for analysis i), a fiducial cosmology with constant dark energy equation of state. We show the results when the Fisher matrix formalism is applied to the 2-D angular power spectrum in the standard Newtonian case and in the case in which general relativistic corrections are included. The errors in the two prescriptions are very similar. The biases in the cosmological parameters are also presented, and will have very little impact in the measurement of the cosmological parameters, as can be noticed from their sizes.

Table IV presents the analogous but for the analysis ii) with non–Gaussianities. Notice that the errors are exactly the same for the two prescriptions and therefore there is no improvement in the determination of the cosmological parameters when the general relativistic corrections are addressed in the angular power spectrum. The biases induced in the cosmological parameters when the data are fitted to the standard Newtonian power spectrum are also presented. These biases are always smaller than the corresponding 1-σ marginalized errors and therefore, will have no impact on the extraction of the cosmological parameters. Also, we find no significant shifts in the values of the cosmological parameters in any of the two prescriptions when the non–Gaussianity parameter $f_{\text{NL}}$ is (wrongly) assumed to be zero. Consequently, from what regards the 2-D angular power spectrum, relativistic corrections will not have any impact on future measurements of the cosmological parameters, even if the information contained at the largest scales becomes at reach.

Notice that, as expected, the errors on the cosmological parameters obtained exploiting the 2-D power spectrum are, in general, larger than in the 3-D case. In the case of analysis i), the expected errors on $w$ differ by one order of magnitude. The results of the 2-D and 3-D analysis should however roughly match in the limit of many narrow redshift bins. We have thus carried out a new fisher matrix analysis, decreasing the size of the redshift bin one order of magnitude in the 2-D analysis. In the latter case, similar marginalized errors are obtained when exploiting 2-D or 3-D power spectrum. In the case of the non–Gaussianity parameter $f_{\text{NL}}$, the errors are three orders of magnitude larger when using the 2-D angular information. This is due to the fact that the 2-D $C_\ell$ angular power spectrum is essentially sensitive to modes transverse to the line of sight, while the 3-D $P(k)$ power spectrum benefit from extra information from the radial modes.

| Parameter | $C_\ell_{\Delta_{\text{st}}}$ | $C_\ell_{\Delta_{\text{obs}}}$ | Biases |
|----------|-----------------|-----------------|-------|
| $\Delta(\Omega_{\text{dm}}h^2)$ | 0.0088 | 0.0086 | 0.003 |
| $\Delta(\Omega_{\text{b}}h^2)$ | 0.002 | 0.002 | $< 10^{-4}$ |
| $\Delta A_s$ | 0.093 | 0.093 | −0.03 |
| $\Delta h$ | 0.045 | 0.045 | 0.003 |
| $\Delta n_s$ | 0.04 | 0.04 | −0.02 |
| $\Delta w$ | 0.24 | 0.24 | 0.01 |

TABLE III: 1-σ marginalized errors from the Euclid-like survey considered here for a fiducial cosmology with a constant dark energy equation of state with a fiducial value $w = -1$. The biases in the parameters are also presented. The error on the amplitude of the primordial fluctuations $\Delta A_s$ is quoted in units of $2.64 \cdot 10^{-9}$.

V. SUMMARY

The complete general relativistic description of the observed matter power spectrum at large scales is significantly different than the standard Newtonian one. The observed redshift and position of galaxies are
TABLE IV: 1−σ marginalized errors from the Euclid-like survey data for a fiducial cosmology with a constant dark energy equation of state, with fiducial values \( w = -1, f_{\text{NL}} = 20, c_s^4 = 1 \). The third row presents the biases induced in the cosmological parameters when general relativistic corrections are neglected. The shifts in the cosmological parameters when \( f_{\text{NL}} \) is set to zero but the data are generated with \( f_{\text{NL}} = 20 \) have been computed including general relativity corrections. Similar results are obtained using the standard Newtonian expression.

affected by the different matter fluctuations and by the gravity waves between the source galaxies and the observer, see Refs. [2–5]. In this paper we have studied the role of relativistic effects in the extraction of different cosmological parameters with the galaxy power spectrum measurements that will be available from future surveys.

We have explored the impact of such corrections in several cosmological scenarios as: constant (but \( w \neq 1 \)) dark energy equation of state, time varying \( w(a) = w_0 + w_a(1-a) \) dark energy equation of state, coupled dark matter dark energy scenario, massive neutrinos and primordial non–Gaussianities. We have performed a Fisher matrix analysis considering data from a future Euclid–like spectroscopic galaxy survey for two scenarios: one with a constant dark energy equation of state, the other with non–Gaussianities. We find that general relativistic corrections will not interfere neither with the extraction of the standard cosmological parameters (as the cold dark matter and baryon densities) nor with the measurement of primordial non–Gaussianities. The expected marginalized errors when relativistic corrections are included in the matter or halo power spectra are very similar to those obtained in the standard Newtonian case. The biases induced in the different cosmological parameters when neglecting these relativistic effects are also negligible. We conclude that the measurement of the cosmological parameters will not be compromised by the presence of general relativistic effects, once they will be included in the analysis.

VI. ACKNOWLEDGMENTS

The authors would like to acknowledge R. de Putter, C. Peña Garay and L. Verde for very useful comments and enlightening discussions. O.M. is supported by AYA2008-03531 and the Consolider Ingenio-2010 project CSD2007-00060. L. L. H is supported in part by the ISN and by the Belgian Science Policy (IAP VI/11). S. Rigolin acknowledges the partial support of an Excellence Grant of Fondazione Cariparo and of the European Program Unification in the LHC era under the contract PITN- GA-2009-237920 (UNILHC).

Appendix A: Gauge invariant formalism

The conventions we use are from Ref. [67] with a few exceptions. More details can be found in Ref. [47]. For perturbations in a flat space time, the perturbation variables can be expanded by harmonic functions \( Y^{(S)}(x,k) \) satisfying \( (\nabla_x + k^2)Y^{(S)} = 0 \). In the following we focus on scalar perturbations, for which we define:

\[
Y^{(S)}_i = \frac{1}{k} Y^{(S)}_i , \tag{A1}
\]

\[
Y^{(S)}_{ij} = \frac{1}{k^2} Y^{(S)}_{ij} + \frac{1}{3} \gamma_{ij} Y^{(S)} . \tag{A2}
\]
Following Ref. [67], the FRW metric, up to first order in perturbation theory, can be written as:

\[ g_{\mu\nu}dx^\mu dx^\nu = \bar{a}^2 \left[ -(1 + 2A)dt^2 - 2B_i dr dx^i + (\gamma_{ij} + 2H_{ij})dx^i dx^j \right], \]  

(A3)

where \( \gamma_{ij} \) is the 3D flat metric with positive signature. The perturbations \( A, B_i \) and \( H_{ij} \) are functions of time and space and are in general gauge-dependent. Expanding the independent perturbations in the Fourier basis, and keeping only the scalar modes, we denote:

\[ A \rightarrow \bar{A}Y(S); \]
\[ B_i \rightarrow \bar{B}Y_i(S); \]
\[ H_{ij} \rightarrow \bar{H}_L\gamma_{ij}Y(S) + \bar{H}_T Y_{ij}(S). \]

In the following, for the sake of simplicity, we will omit the tilde symbols in the notation. Remember that all these quantities are represented by the correspondent Fourier expansion and depend only on time and on the 3-momentum \( k \), while the position dependence is left only in the \( Y \) basis elements.

Using these metric perturbations, we can now define \( \sigma_g \), the shear perturbation and \( R \), the curvature perturbation, as

\[ \sigma_g = \frac{1}{k} \left( H_T - kB \right); \]  
\[ R = H_L + \frac{1}{3} H_T, \]  

(A4)

(A5)

which are no gauge invariant quantities. The Bardeen metric gauge invariants are defined as [68]:

\[ \Psi_B = A - \frac{H}{k} \sigma_g - \frac{1}{k} \dot{\sigma}_g, \]
\[ \Phi_B = H_L + \frac{1}{3} H_T - \frac{H}{k} \sigma_g. \]

(A6)

(A7)

In the same line one can define perturbations for the energy–density for a given fluid \( a \):

\[ u^\mu_a = \frac{1}{a} \left( 1 - A, v_i^a \right); \]
\[ T_{\mu\nu}^a = \rho_a (1 + \delta_a) u^\mu_a u^\nu_a + \tau_{\mu\nu}, \]

(A8)

(A9)

where \( v_i^a \) is the peculiar velocity perturbation of the fluid and \( \delta_a \) the fluid matter density contrast. Following [67] one define the following gauge-invariant quantities:

\[ V_a = v_a - \frac{\dot{H}_T}{k}; \]
\[ \Delta_a = \delta_a - \frac{\dot{\rho}_a}{\rho_a} \frac{R}{H}, \]

(A10)

(A11)

where \( \Delta_a \) is the gauge invariant density contrast for the fluid \( a \) defined in the gravity rest frame. Notice that \( v_i^a = v_a Y_i \) and that in Eq. (9) and the following, \( V^i \) refers to the gauge invariant velocity perturbation associated to the matter component, i.e. \( V^i \equiv V_m^i = V_m Y^i \).

1. Photon wave vector: some relations

Here we provide several relations resulting from the null energy condition \( K^\mu K_\mu = 0 \) and the geodesic equations \( K^\mu K^\nu_a = 0 \) useful in the derivation of the expression of gauge invariant matter density perturbation \( \Delta_a \) defined in Eq. (17). On the one hand, from the perturbed null equation \( K^\mu K_\mu = 0 \), one obtains the following relation between the temporal and spatial null vector perturbations:

\[ n^i \delta n_i = \frac{\delta \nu}{\nu} + (\Psi_B - \Phi_B) - \frac{1}{k^2} \frac{d}{d\lambda} \left( \frac{dH_T}{d\lambda} - 2H_T + kB \right), \]

(A12)
where \( \frac{d}{d\lambda} = \partial_{\tau} + n^i \partial_i \) and we have taken into account that the background null equation imposes \( n_i n_i = 1 \). We have also used the background geodesic equation giving rise to \( n_i \partial_j n^i = n_i \dot{n}_i = 0 \). On the other hand, the temporal geodesic equation \( K_{\nu}^\nu K_{\nu}^0 \) gives the following condition:

\[
\frac{d}{d\lambda} \left( \frac{\delta \nu}{\nu} + 2 \Psi_B \right) = \left( \dot{\Psi}_B - \dot{\Phi}_B \right) - \frac{1}{k} \frac{d}{d\lambda} \left( \frac{d\sigma_g}{d\lambda} + 2 \mathcal{H} \sigma_g \right). \tag{A13}
\]

\[2. \quad \text{Newtonian gauge}\]

It can be useful for comparison to make a particular gauge choice. In the Newtonian gauge, \( \sigma_g = 0 \) and the perturbed metric is reduced to:

\[
ds^2 = a^2 \left[ -(1 + 2 \Psi_N) d\tau^2 + (1 - 2 \Phi_N) dx^i dx_i \right]. \tag{A14}\]

In particular, for this gauge choice metric perturbations are given by:

\[
\Psi_N = \Psi_B = A, \quad \Phi_N = -\Phi_B = -R. \tag{A15}\]

The convergence \( \kappa \), in the Newtonian gauge, reads:

\[
\kappa = \int_0^{r_s} \frac{r_s - r}{2r_s^2} \Delta_\Omega (\Phi_N + \Psi_N), \tag{A16}\]

where \( r_s \) is the comoving distance between the source and the observer and \( \Delta_\Omega = \cot \theta \partial_\theta + \partial_\theta^2 + 1/ \sin^2 \theta \partial_\phi^2 \) is the angular laplacian on a unit sphere.
