Long-time asymptotics for the focusing Fokas-Lenells equation in the solitonic region of space-time

Qiaoyuan Cheng, Engui Fan

Abstract

We study the long-time asymptotic behavior of the focusing Fokas-Lenells (FL) equation

$$u_{tx} + \alpha \beta^2 u - 2i\alpha\beta u_x - \alpha u_{xx} - i\alpha \beta^2 |u|^2 u_x = 0$$

with generic initial data in a Sobolev space which supports bright soliton solutions. The FL equation is an integrable generalization of the well-known Schrodinger equation, and also linked to the derivative Schrodinger model, but it exhibits several different characteristics from theirs. (i) The Lax pair of the FL equation involves an additional spectral singularity at $k = 0$. (ii) four stationary phase points will appear during asymptotic analysis, which require a more detailed necessary description to obtain the long-time asymptotics of the focusing FL equation. Based on the Riemann-Hilbert problem for the initial value problem of the focusing FL equation, we show that inside any fixed time-spatial cone

$$\mathcal{C}(x_1, x_2, v_1, v_2) = \{(x, t) \in \mathbb{R}^2 | x = x_0 + vt, x_0 \in [x_1, x_2], v \in [v_1, v_2]\},$$

the long-time asymptotic behavior of the solution $u(x, t)$ for the focusing FL equation can be characterized with an $N(2)$-soliton on discrete spectrums and a leading order term $O(|t|^{-1/2})$ on continuous spectrum up to a residual error order $O(|t|^{-3/4})$. The main tool is the $\mathcal{J}$ nonlinear steepest descent method and the $\mathcal{J}$-analysis.

**Keywords:** Focusing Fokas-Lenells equation, Riemann-Hilbert problem, $\mathcal{J}$ steepest descent method, long-time asymptotics, soliton resolution.

1 Introduction

The study of long-time behaviors of solutions to nonlinear integrable systems goes back to the work of Zakharov and Manakov [1]. Using the monodromy theory, It was able to reduce the Riemann-Hilbert (RH) problem formulation for the Schrödinger (NLS) equation to a model case, which can then be solved explicitly, giving the desired asymptotics [2]. Deift and Zhou developed a rigorous nonlinear steepest descent method to study the oscillatory RH problem associated with the mKdV equation [3]. Later it becomes a powerful tool for the long-time asymptotics of the integrable nonlinear evolution equations, such as the NLS equation [4, 5], the KdV equation [6], the Camassa-Holm equation [7, 8], the modified Camassa-Holm equation [9], the Degasperis-Procesi equation [10, 11], the sine-Gordon equation [12, 13], the Fokas-Lenells equation [14] and so on. Recently the Deift-Zhou steepest descent method was further extended to the ∂-steepest descent method of McLaughlin and Miller, which first appeared in the orthogonal polynomial setting [15, 16].

The ∂-method follows the general scheme of the Deift-Zhou steepest descent argument, while the nonanalytic data are now continued to the desired contours via the solution of a ∂-equation. The ∂-steepest descent method allows asymptotic analysis for nonanalytic phases with two Lipschitz derivatives near the stationary points. This method was adapted to obtain the long-time asymptotics for solutions to the NLS equation and the derivative NLS equation, with a sharp error bound for the weighted Sobolev initial data [17–20].

In this paper we study the long-time asymptotic behavior of the Fokas-Lenells (FL) equation

\[
\frac{\partial u}{\partial t} + \alpha \beta^2 u - 2i\alpha \beta u_x - \alpha u_{xx} + \sigma i\alpha \beta^2 |u|^2 u_x = 0,
\]

(1.1)

which is an integrable generalization of nonlinear Schrödinger equation, and is also related to the derivative NLS model. As is well-known, the Camassa-Holm equation can be mathematically derived by utilizing the two Hamiltonian operators associated with the KdV equation [21]. Similarly, by utilizing the two Hamiltonian operators associated with the NLS equation, it is possible to derive the FL equation [22]. In optics, considering suitable higher-order linear and nonlinear optical effects, the FL equation has been derived as a model to describe the femtosecond pulse propagation through single mode optical silica fiber, for which several
interesting solutions have been constructed. It also belongs to the deformed derivative NLS hierarchy proposed by Kundu [23, 24].

The soliton solutions for the FL equation have been constructed by the inverse scattering transform method and the dressing method [25, 26]. Matsumo obtained the bright and the dark soliton solutions for the FL equation by using the Hirota method [27, 28]. The double Wronskian solutions for the FL equation was further given via bilinear approach [29]. The lattice representation and the n-dark solitons of the FL equation have been presented in [30]. The breather solutions of the FL equation have also been constructed via a dressing-Bäcklund transformation related to the RH problem formulation [31]. It has been shown that the periodic initial value problem for the FL equation is well-posed in a Sobolev space [32]. A kind of rogue wave solution for the FL equation were obtained by using the Darboux transformation [33]. The Fokas method was used to investigate the initial-boundary value problem for the FL equation on the half-line and a finite interval, respectively [34, 35]. An algebro-geometric method was used to obtain algebro-geometric solutions for the FL equation [36]. The explicit one-soliton of the initial value problem for the FL equation was given by the RH method [37]. The inverse scattering transformation for the FL equation with nonzero boundary conditions was further investigated by using the RH method [38].

It is noted that for the defocusing case \( \sigma = 1 \), the FL equation (1.1) with zero boundary conditions does not admit a soliton solution. For the Schwartz initial value \( u(x,0) \in S(\mathbb{R}) \), Xu obtained the long-time asymptotics for the FL equation without solitons by using the Deift-Zhou method [14]. However, for the focusing case \( \sigma = -1 \), the FL equation (1.1) takes

\[
\begin{align*}
    u_{tx} + \alpha \beta^2 u - 2i\alpha \beta u_x - \alpha u_{xx} - i\alpha \beta^2 |u|^2 u_x &= 0, \\
u(x,0) &= u_0(x),
\end{align*}
\]

whose soliton solutions will appear for zero boundary conditions which correspond to discrete spectrums. In this case, the long-time asymptotic behavior of solutions is more complicated than the defocusing case due to the presence of solitons. A more detailed necessary description on the asymptotic analysis and some new techniques have to be adapted.

In this work, we apply the \( \partial \)-techniques to obtain the long-time asymptotic behavior of solutions to the focusing FL equation (1.2) with a Sobolev initial data \( u_0(x) \in H^{3,3}(\mathbb{R}) \). Comparing with the classical NLS equation and the derivative NLS equation [18–20], to conduct an asymptotic analysis on the FL equation (1.2) confronts with the following complications,
The FL equation (1.2) belongs to a negative hierarchy, with two spectral singularities at $k = 0$ and $k = \infty$ involved in its Lax pair.

In comparison with the FL spectral problem (2.1), the Zakharov-Shabat spectral problem has no multiplication of matrix potential $U_x$ by $k$. As a result, Neumann series solutions for the Jost functions of Zakharov-Shabat spectral problem converge if $u_0(x) \in L^1(\mathbb{R})$. However, for the FL spectral problem (2.1), the Volterra equation will involve the term $ku_0(x)$ (see (2.14) in next section), which is not $L^2(\mathbb{R})$ bounded since $k$ may go to infinity. Through the small $k$ and large $k$ estimates respectively, we overcome this difficulty and prove the existence and the differentiability of the eigenfunctions, further establish the scattering map from the initial data $u_0(x)$ to the scattering coefficient $r(k)$.

In the RH problem of the FL equation (1.2), the oscillatory term $e^{i\theta(k)}$ involves four stationary phase points: $z_1, z_3$ are located on the real axis and $z_2, z_4$ are located on the imaginary axis. The corresponding local models need two kinds of parabolic cylinder models to described in asymptotic analysis. To simplify the expression of the RH problem formula in our analysis, we propose to use a uniform parabolic cylinder model to match the solvable RH model of the four stationary phase points.

When the variables $x$ and $t$ change inside a time-spatial cone $\mathcal{C}(x_1, x_2, v_1, v_2)$, the corresponding discrete spectrums fall in a band region $-v_2/2 < \text{Re}(k) < -v_1/2$ for the NLS equation and derivative NLS equation [18–20], while for our FL equation, the discrete spectrums fall in a tyre region $f(v_1) < |k| < f(v_2)$ (please see Figure 8 in Section 7).

The structure of the paper is as follows. In Section 2, based on the Lax pair of the FL equation (1.2) and through the small $k$ and large $k$ estimates, we prove the existence and the differentiability of the eigenfunctions. We also establish the scattering map from the initial data to the scattering coefficients, and study the analyticity, the symmetries and the asymptotics of the eigenfunctions. In Section 3, inspired by [14], we construct a RH problem for $M(k)$ to formulate the initial value problem of the FL equation. In our Section 4, we prove the existence and uniqueness of the RH problem. We first show that the Beals-Coifman integral equation associated with the RH problem has a unique solution. Then we give a reconstruction formula for the potential $u$ in terms of the solution $\mu(k)$ of the Beals-Coifman
integral equation. In Section 5, we introduce a function $T(k)$ to transform $M(k)$ into a new RH problem for $M^{(1)}(k)$, which admits a regular discrete spectrum and two triangular decompositions of the jump matrix near four stationary-phase points $z_n$, $n = 1, 2, 3, 4$. By introducing a matrix-valued function $R^{(2)}(k)$, we obtain a mixed $\partial$-RH problem for $M^{(2)}(k)$ by a continuous extension of the $M^{(1)}(k)$. In Section 5.3, we decompose $M^{(2)}(k)$ into a model RH problem for $M^{(3)}(k)$ and a pure $\partial$-Problem for $M^{(3)}(k)$. The $M^{rhp}(k)$ can be obtained via an outer model $M^{(out)}(k)$ for the soliton components to be solved in Section 6, and an inner model $M^{(in)}(k)$ which are approximated by a solvable model for $M^{HF}(k)$ obtained in Section 7. In Section 8, we compute the error function $E(k)$ with a small-norm RH problem. In Section 9, we analyze the $\partial$-problem for $M^{(3)}(k)$. Finally, in Section 10, based on the results obtained above, we find a decomposition formula

$$M(k) = M^{(3)}(k)E(k)M^{(out)}(k)R^{(2)}(k)^{-1}T(k)^{\sigma_3}, \quad (1.4)$$

which leads to the long-time asymptotic behavior for the solutions of the initial value problem (1.2)-(1.3) for the FL equation.

2 Spectral analysis on Lax pair

In this section, we show the well-posedness for the initial value problem of the Fokas-Lenells (FL) equation (1.2). We prove the existence of the eigenfunctions and establish the scattering map from the initial data to the scattering coefficients.

2.1 Existence and differentiability of eigenfunctions

The FL equation (1.2) admits the Lax pair

$$\begin{cases} 
\psi_x + ik^2 \sigma_3 \psi = kU_x \psi, \\
\psi_t + i\eta^2 \sigma_3 \psi = V \psi,
\end{cases} \quad (2.1)$$

where $\psi = \psi(x, t, k)$, and

$$\sigma_3 = \begin{pmatrix} 1 & 0 \\
0 & -1 \end{pmatrix}, \quad U = \begin{pmatrix} 0 & u \\
-\bar{u} & 0 \end{pmatrix}, \quad (2.2)$$

$$\eta = \sqrt{\alpha(k - \beta^2/2k)}, \quad V = \alpha k U_x + \frac{i\alpha \beta^2}{2} \sigma_3 \left( \frac{1}{k} U - U^2 \right).$$

With the transformation

$$\psi = \varphi e^{-i(k^2 x + \sigma^2 t) \sigma_3}, \quad (2.3)$$

$$\varphi = e^{-i(k^2 t + \sigma^2 t) \sigma_3},$$

$$\psi = \varphi e^{-i(k^2 x + \sigma^2 t) \sigma_3}, \quad (2.3)$$
\( \varphi \) satisfies a new Lax pair

\[
\begin{aligned}
\varphi_x + ik^2[\sigma_3, \varphi] &= kU_x \varphi, \\
\varphi_t + i\eta^2[\sigma_3, \varphi] &= V \varphi,
\end{aligned}
\tag{2.4}
\]

which can be written in the full derivative form

\[
d(e^{i(k^2x+\eta^2t) \hat{\sigma}_3} \varphi) = e^{i(k^2x+\eta^2t) \hat{\sigma}_3} (kU_x dx + V dt) \varphi,
\tag{2.5}
\]

The Lax pair (2.4) has singularities at \( k = 0 \) and \( k = \infty \), which is different from NLS and derivative NLS equations. To control the behavior of solutions of (2.4) and construct the solution \( u(x, t) \) of the FL equation (1.2), we should resort to the \( t \)-part and the expansion of the eigenfunction as the spectral parameter \( k \to 0 \). Specifically, we consider two different asymptotic expansions respectively to analyze these two singularities \( k = 0 \) and \( k = \infty \).

From the Lax pair (2.4), we obtain the following asymptotic expansion

\[
\begin{aligned}
\varphi(x, t, k) &= I + kU + \mathcal{O}(k^2), \quad k \to 0, \\
\varphi(x, t, k) &= \varphi_0 + \mathcal{O}(k^{-1}), \quad k \to \infty,
\end{aligned}
\tag{2.6}
\]

where \( U \) is given by (2.2) and

\[
\varphi_0(x, t) = e^{-\frac{i}{2} \int_{-\infty}^{x} |u_y(y, t)|^2 dy \hat{\sigma}_3}.
\tag{2.8}
\]

We introduce a new function \( \omega = \omega(x, t, k) \) by

\[
\varphi(x, t, k) = \varphi_0(x, t) \omega(x, t, k),
\tag{2.9}
\]

which satisfies the Lax pair

\[
\begin{aligned}
\omega_x + ik^2[\sigma_3, \omega] &= V_1 \omega, \\
\omega_t + i\eta^2[\sigma_3, \omega] &= V_2 \omega,
\end{aligned}
\tag{2.10}
\]

and can be written in full derivative form

\[
d\left(e^{i(k^2x+\eta^2t) \hat{\sigma}_3} \omega\right) = W(x, t, k),
\tag{2.12}
\]

where

\[
W(x, t, k) = e^{i(k^2x+\eta^2t) \hat{\sigma}_3} (V_1 dx + V_2 dt) \omega,
\tag{2.13}
\]

and the matrices \( V_1 \) and \( V_2 \) are given respectively, by

\[
\begin{aligned}
V_1 &= e^{\frac{i}{2} \int_{-\infty}^{x} |u_y(y, t)|^2 dy \hat{\sigma}_3} (kU_x + \frac{i}{2} |u_x|^2 \sigma_3), \\
V_2 &= e^{\frac{i}{2} \int_{-\infty}^{x} |u_y(y, t)|^2 dy \hat{\sigma}_3} (V + \frac{ia}{2} (|u_x|^2 - \beta^2 |u|^2) \sigma_3).
\end{aligned}
\]
Now we conduct a spectral analysis on the $x$-part of (2.10). Since the analysis takes place at a fixed time, the $t$-dependence will be suppressed. Define two solutions $\omega^\pm(x,k)$ of the $x$-part of (2.10) by

$$\omega^\pm(x,k) = I + \int_{\pm\infty}^x e^{-ik^2(x-y)^2} (V_1\omega^\pm)(y,k)\,dy.$$  \hspace{1cm} (2.14)

Denoting $\omega^\pm(x,k) = (\omega_1^\pm, \omega_2^\pm)$, where the scripts 1 and 2 denote the first and second columns of $\omega^\pm(x,k)$, we have

![Figure 1: The analytical domains $D^+$ and $D^-$ for $\omega^\pm(x,k)$.](image)

**Proposition 1.** For $u(x,0) \in H^{3,3}(\mathbb{R})$, there exist unique eigenfunctions $\omega^\pm(x,k)$ which satisfy (2.14), respectively. Moreover, $\omega_1^+(x,k)$, $\omega_2^+(x,k)$ and $a(k)$ are analytical in $D^+$; $\omega_1^-(x,k)$ and $\omega_2^-(x,k)$ are analytical in $D^-$, where

$$D^+ = \{k : \text{Im}k^2 > 0\}, \quad D^- = \{k : \text{Im}k^2 < 0\},$$

as Figure 1 shows.

By denoting $\omega^\pm(x,k) = (\omega_1^\pm(x,k))$, from (2.14), we obtain two integral equations

$$\omega_{11}^\pm(x,k) = 1 - \int_x^{\pm\infty} ku_y(y)\omega_{21}^\pm(y)\,dy - \int_x^{\pm\infty} \frac{i}{2} |u_y(y)|^2 \omega_{11}^\pm(y,k)\,dy,$$  \hspace{1cm} (2.15)

$$\omega_{21}^\pm(x,k) = \int_x^{\pm\infty} e^{2ik^2(x-y)} ku_y(y)\omega_{11}^\pm(y,k)\,dy + \frac{i}{2} \int_x^{\pm\infty} e^{2ik^2(x-y)} |u_y(y)|^2 \omega_{21}^\pm(y,k)\,dy.$$  \hspace{1cm} (2.16)
where \( \bar{u}_x(x) \) is the substitution of \( \bar{u}_x e^{i \int_{-\infty}^{x} |u_y(y, t)|^2} \).

Without loss of generality, we take \( \omega_1^+ = (\omega_{11}^+, \omega_{21}^+)^T \) as an illustrative example to prove Proposition 1 from the small-\( k \) estimates and large-\( k \) estimates.

### 2.1.1 Small-\( k \) estimates

By denoting
\[
w = (\omega_{11}^+ - 1, \omega_{21}^+)^T,
\]
we write (2.15) – (2.16) as the form
\[
w = w_0 + T_0 w, \quad w_0 \equiv T_0 e_1,
\]
where \( T_0 \) is an integral operator defined by
\[
(T_0 h)(x) = \int_{-\infty}^{x} K_0(x, y, k) h(y) dy,
\]
and
\[
K_0(x, y, k) = \begin{pmatrix}
-\frac{i}{2} |u_y|^2 & -k u_y \\
\frac{1}{2} i u_y e^{2ik^2(x-y)} k \bar{u}_y & \frac{1}{2} |u_y|^2
\end{pmatrix}.
\]
To study the \( k \)-derivatives of the solution, we solve the integral equations
\[
w_k = w_{0,k} + T_{0,k} w + T_0 (w_k).
\]

### A. Estimates on \( w_0, T_0 \) and their derivatives

In this part, we derive estimates on the terms \( w_0, T_0 \) and their derivatives with respect to \( k \), which we later use to estimate \( r(k) \) and \( r'(k) \).

**Lemma 1.** For \( k \in I_0 = \{ k \in \mathbb{R} \cup i \mathbb{R} : |k| < 1 \} \), we have the following estimates
\[
\|w_0\|_{C^0([0, L_0^2])} \lesssim \|u\|_{H^2,2},
\]
\[
\|w_0\|_{L^2([0, L_0^2])} \lesssim \|u\|_{H^3,3},
\]
\[
\|w_{0,k}\|_{C^0([0, L_0^2])} \lesssim \|u\|_{H^2,2},
\]
\[
\|w_{0,k}\|_{L^2([0, L_0^2])} \lesssim \|u\|_{H^2,2}.
\]

**Proof.** Noting that
\[
w_0 = \left( \int_{-\infty}^{x} -\frac{i}{2} |u_y|^2 dy, \int_{-\infty}^{x} e^{2ik^2(x-y)} k \bar{u}_y dy \right)^T,
\]
whose first component is independent of \( k \), bounded by \( \| u \|_{H^1} \).

By letting \( \varphi \in C_0^\infty (I_0) \), we compute

\[
\left\| \int_x^\infty e^{2ik^2(x-y)}k\bar{u}(y)dy \right\|_{L^2(I_0)}^2 = \sup_{\| \varphi \| = 1} \int_{I_0} \varphi(k) \int_x^\infty e^{2ik^2(x-y)}ku_y(y)dy \lesssim c\| u_y \|_{L^1},
\]

The first estimate is immediate and the second follows by integration in \( x \). Therefore for the second component, we have

\[
\int_{\mathbb{R}^+} \int_{I_0} \left| \int_x^\infty e^{2ik^2(x-y)}ku_y(y)dy \right|^2 dkdx \lesssim \int_{\mathbb{R}^+} \left| \int_x^\infty e^{2ik^2(x-y)}ku_y(y)dy \right|^2 dx \lesssim \| u \|_{L^{1,1}} \| u_y \|_{L^1}.
\]

Noting that

\[
w_{0,k} = \left( \int_x^\infty 0 \right),
\]

where

\[
g(x, y, k) = e^{2ik^2(x-y)}(1 + 4ik^2)(x - y)\bar{u}_y(y),
\]

the estimates of \( w_{0,k} \) can be obtained in the same way.

\[\square\]

The operator \( T_{0,k} \) induces linear mappings from \( L^2(\mathbb{R}^+ \times I_0) \) to \( L^2(\mathbb{R}^+ \times I_0) \) and \( C^0(\mathbb{R}^+, L^2(I_0)) \) by the formula \( g(x, k) = T_{0,k}(f(\cdot, k))(x) \) respectively. We need the following estimates on these induced maps.

**Lemma 2.** Suppose that \( u(x, 0) \in H^{3,3}(\mathbb{R}) \), the following operator bounds hold uniformly and the operators are Lipschitz functions of \( u \).

\[
\| T_0 \|_{L^2(\mathbb{R}^+ \times I_0) \rightarrow C^0(\mathbb{R}^+, L^2(I_0))} \lesssim \| u \|_{H^{3,2}},
\]

\[
\| T_{0,k} \|_{L^2(\mathbb{R}^+ \times I_0) \rightarrow L^2(\mathbb{R}^+ \times I_0)} \lesssim \| u \|_{H^{3,3}},
\]

\[
\| T_{0,k} \|_{L^2(\mathbb{R}^+ \times I_0) \rightarrow C^0(\mathbb{R}^+, L^2(I_0))} \lesssim \| u \|_{H^{3,3}}.
\]

**Proof.** For an operator \( T_0(k) \) with an integral kernel \( K(x, y, k) \) satisfying the estimate

\[
\sup_{k \in I_0} |K(x, y, k)| \leq h(y),
\]

and satisfying \( K(x, y, k) = 0 \) if \( x > y \), the \( L^2(\mathbb{R}^+ \times I_0) \)-norm is controlled by

\[
\left( \int_0^\infty \int_x^\infty h(y)^2 dy dx \right)^{1/2} = \left( \int_0^\infty y h(y)^2 dy \right)^{1/2},
\]

\[\square\]
and the norm from $L^2(\mathbb{R}^+ \times I_0)$ to $C^0(\mathbb{R}^+, L^2(I_0))$ is controlled by $\sup_x \left( \int_0^\infty h(y)^2 dy \right)^{1/2}$. The conclusions follow from this observation and the estimates

$$\int_{I_0} \varphi(k) \int_x^\infty |g(x, y, k)| dy \, dk \leq \int_{I_0} \varphi(k) \left( \int_x^\infty e^{2ik^2(x-y)} \bar{u}_y dy + \int_x^\infty |4ik^2 e^{2ik^2(x-y)} \bar{u}_y dy \right) \, dk$$

$$\leq c(\int_{I_0} \varphi(k)^2 \, dk)^{1/2} \int_x^\infty |\bar{u}_y| dy \lesssim ||\varphi||_{L^2} ||u||_{H^{1,1}}.$$  

B. Resolvent estimates

With the following lemma, we obtain the resolvent estimates in Lemma 4.

**Lemma 3.** Suppose that $X$ is a Banach space and consider the Volterra-type integral equation

$$u(x) = f(x) + (Tu)(x), \quad (2.29)$$
on the space $C^0(\mathbb{R}^+, X)$, where $f \in C^0(\mathbb{R}^+, X)$ and $T$ is an integral operator on $C^0(\mathbb{R}^+, X)$. Let $f^*(x) = \sup_{y \geq x} \|f(y)\|_X$, and assume there is a nonnegative function $h \in L^1(\mathbb{R}^+)$ such that

$$(Tf)^*(x) \leq \int_x^\infty h(t) f^*(t) \, dt.$$  

Then the equation (2.29) has a unique solution for each $f$. Moreover, the resolvent $(I - T)^{-1}$ obeys the bound

$$\|(I - T)^{-1}\|_{(C^0(\mathbb{R}^+, X))} \leq \exp \left( \int_0^\infty h(t) \, dt \right).$$

Our construction of the resolvent is based on the estimate

$$(T_0f)^*(x) \leq \int_x^\infty \sigma(y) f^*(y) dy. \quad (2.30)$$

In what follows, we define

$$\sigma(y) = 2|u_y(y)| + |iu_y(y)|^2,$$

which implies $\|\sigma\|_{L^1}$ and $\|\sigma\|_{L^{2,2}}$ since $u \in H^{3,3}(\mathbb{R})$.

**Lemma 4.** For each $k \in \mathbb{R} \cup i\mathbb{R}$ and $u(x, 0) \in H^{3,3}(\mathbb{R})$, the operator $(I - T_0)^{-1}$ exists as a bounded operator from $C^0(\mathbb{R}^+) \otimes \mathbb{C}^2$ to itself. Moreover, $(I - T_0)^{-1} - I$ is an integral operator with a continuous integral kernel $L_0(x, y, k)$ such that $L_0(x, y, k) = 0$ for $x > y$. The integral kernel $L_0(x, y, k)$ satisfies the estimate

$$|L_0(x, y, k)| \leq \exp (\|\sigma\|_{L^1}) \sigma(y). \quad (2.31)$$
**Proof.** Since \( T_0 \) is a Volterra operator, we can obtain precise estimates on the resolvent through the Volterra series. The integral kernel \( K_0(x, y, k) \) obeys the estimate \(|K_0(x, y, k)| \leq \sigma(y)\). The operator

\[
L_0 \equiv (I - T_0)^{-1} - I,
\]

is an integral operator with an integral kernel \( L_0(x, y, k) \) given by

\[
L_0(x, y, k) = \begin{cases} \sum_{n=1}^{\infty} K_n(x, y, k), & x \leq y, \\ 0, & x > y, \end{cases}
\]

where

\[
K_n(x, y, k) = \int_{x \leq y_1 \leq \cdots \leq y_{n-1}} K_0(x, y_1, k) K_0(y_1, y_2, k) \cdots K_0(y_{n-1}, y_1, k) \, dy_{n-1} \cdots dy_1,
\]

and the estimate

\[
|K_n(x, y, k)| \leq \frac{1}{(n-1)!} \left( \int_{x}^{\infty} \sigma(t) \right)^{n-1} \sigma(y),
\]

holds. Therefore follows the estimate (2.31). \( \square \)

Now, we use the above estimates to solve (2.18) and (2.20). We first present the results here.

**Proposition 2.** We suppose that \( u(x, 0) \in H^{3,3}(\mathbb{R}) \) and \( I_0 = \{ k \in \mathbb{R} \cup i\mathbb{R} : |k| < 1 \} \), then there exists a unique solution \( w \in C^0(\mathbb{R}^+, L^2(I_0)) \cap L^2(\mathbb{R}^+ \times I_0) \) for (2.18) for each \( k \in I_0 \) satisfies:

(i) The map \( u(x, 0) \rightarrow w(x, k) \) is Lipschitz continuous from \( H^{3,3}(\mathbb{R}) \) to \( C^0(\mathbb{R}^+, L^2(I_0)) \cap L^2(\mathbb{R}^+ \times I_0); \)

(ii) The map \( u(x, 0) \rightarrow w_k(x, k) \) is Lipschitz continuous from \( H^{3,3}(\mathbb{R}) \) to \( C^0(\mathbb{R}^+, L^2(I_0)) \cap L^2(\mathbb{R}^+ \times I_0). \)

**2.1.2 Large-\( k \) estimates**

First, we insert (2.10) to evaluate the derivative of \( \omega_{11}^{\pm} \) in the following computation

\[
\omega_{11}^{\pm,x} = \frac{i}{2} |u_x|^2 \omega_{11}^{\pm} + k\bar{u}_x,
\]

from which, by canceling out some opposite terms, we derive

\[
\omega_{11}^{\pm}(x, k) = 1 + i \int_x^{\pm \infty} \bar{u}_y(y) \int_y^{\pm \infty} e^{2ik^2(z-y)} \bar{u}(z) \omega_{11}^{\pm}(z, k) \, dz \, dy,
\]

\[
\omega_{21}^{\pm}(x, k) = -\frac{i}{2k} \bar{u}_x(x) \omega_{11}^{\pm}(x, k) - \frac{i}{2k} \int_x^{\pm \infty} e^{2ik^2(z-y)} \bar{u}(y) \omega_{11}^{\pm}(y, k) \, dy,
\]
where
\[ \tilde{u}(x) = \bar{u}_{xx}(x) + \frac{i}{2} |u_x(x)|^2 \bar{u}_x(x). \]  
(2.38)

As \( \omega_{21}^\pm \) does not occur in the equation for \( \omega_{11}^\pm \), we solve the integral equation (2.36) for \( \omega_{11}^\pm \), and use the solution to compute \( \omega_{21}^\pm \).

We introduce the following notations
\[ \eta_{11}^\pm(x,k) = \omega_{11}^\pm(x,k) - 1, \]  
(2.39)
\[ \eta_{21}^\pm(x,k) = \omega_{21}^\pm(x,k) + \frac{i}{2k} u_x(x), \]  
(2.40)
which will facilitate the extraction of the leading order behavior of \( \omega_{11}^\pm \) and \( \omega_{21}^\pm \) for a large \( k \). From (2.36), (2.37), (2.39) and (2.40), we conclude that
\[ \eta_{11}^\pm(x,k) = F_{\pm}^\pm(x,k) + (T_{\pm} \eta_{11}^\pm)(x,k), \]  
(2.41)
\[ \eta_{21}^\pm(x,k) = G_{\pm}^\pm(x,k) - \frac{i}{2k} u_x(x) \eta_{11}^\pm - \frac{i}{2k} \int_{-\infty}^{\infty} e^{2ik^2(x-y)} \bar{u}(y) \eta_{11}^\pm(y,k) dy, \]  
(2.42)
where
\[ F_{\pm}^\pm(x,k) = - \int_{-\infty}^{\infty} \bar{u}(y) G_{\pm}^\pm(y,k) dy, \]  
(2.43)
\[ G_{\pm}^\pm(x,k) = - \frac{i}{2k} \int_{-\infty}^{\infty} e^{2ik^2(x-y)} \bar{u}(y) dy, \]  
(2.44)
\[ (T_{\pm} f)(x,k) = \frac{i}{2} \int_{-\infty}^{\infty} \bar{u}(y) \int_{y}^{\infty} e^{2ik^2(y-z)} \bar{u}(z) f(z) dz. \]  
(2.45)

Let \( \eta^\pm = (\eta_{11}^\pm, \eta_{21}^\pm) \) and \( I_\infty \equiv \{ k \in \mathbb{R} \cup i \mathbb{R} : |k| > 1 \} \). We utilize the similar method used in the above part to give the existence of \( \omega^\pm \) and \( \omega_{k}^\pm \). To study \( \eta_{11}^\pm \) and \( \eta_{11,k}^\pm \), we take \( k \)-derivatives at both sides of (2.41) which gives
\[ \eta_{11,k}^\pm = F_{\pm,k} + T_{\pm,k} \eta_{11} + T_{\pm} \eta_{11,k}^\pm. \]  
(2.46)

With good estimates for \( \eta_{11}^\pm \) and its derivatives at hands, it is straightforward to prove the corresponding estimates on \( \eta_{21}^\pm \) using (2.42).

In the rest of this part, we drop the \( \pm \) and derive estimates on \( \eta_{11}^\pm \) and \( \eta_{21}^\pm \). Similar procedures can be used to obtain estimates on \( \eta_{11}, \eta_{21} \). For simplicity, we write \( \eta_{11} \) for \( \eta_{11}^\pm \), \( F \) for \( F_+ \), \( T \) for \( T_+ \), etc. Recall that \( I_\infty = \{ k \in \mathbb{R} \cup i \mathbb{R} : |k| > 1 \} \).

**A. Estimates on \( F, G, T \) and their derivatives**

In this part, we mainly give estimates on \( F, G, \) and \( T \), so as their derivatives.
Lemma 5. Suppose $u(x,0) \in H^{3,3}(\mathbb{R})$, the following terms define Lipschitz maps from $H^{3,3}(\mathbb{R})$ into $C^0(\mathbb{R}^+, L^2(I_\infty)) \cap L^2(\mathbb{R}^+ \times I_\infty)$

(i) $G$, (ii) $F$, (iii) $\partial G / \partial k$, (iv) $\partial F / \partial k$.

Proof. Observing that

$$\|F\|_{C^0(\mathbb{R}^+, L^2(I_\infty))} \leq \|u\|_{W^{1,1}} \|kG\|_{C^0(\mathbb{R}^+, L^2(I_\infty))},$$

$$\|F\|_{L^2(\mathbb{R}^+ I_\infty)} \leq \|u\|_{H^1} \|kG\|_{L^2(\mathbb{R}^+ \times I_\infty)},$$

it is obvious that (i) $\Rightarrow$ (ii). To prove (i) we pick $\varphi \in C_0^\infty(I_\infty)$ and mimic the proof of Lemma 1. The Lipschitz continuity follows from the fact that $G$ is linear in $u_x$ and $F$ is bismooth linear in $u_x$.

One can similarly check that (iii) $\Rightarrow$ (iv), so it suffices to prove (iii). Next, we estimate the derivative of $G$. Since

$$\frac{\partial G}{\partial k} = h_1(x, k) + h_2(x, k),$$

with

$$h_1(x, k) = m_1(x, k) + m_2(x, k),$$

$$h_2(x, k) = s_1(x, k) + s_1(x, k),$$

where

$$m_1(x, k) = \frac{i}{4k^2} \int_x^\infty (x - y)e^{2ik^2(x-y)}\bar{u}_ydy,$$

$$m_2(x, k) = -\frac{1}{8k^2} \int_x^\infty (x - y)e^{2ik^2(x-y)}|u_y|^2\bar{u}_ydy,$$

$$s_1(x, k) = 2k \int_x^\infty (x - y)e^{2ik^2(x-y)}\bar{u}_{yy}dy,$$

$$s_2(x, k) = ik \int_x^\infty (x - y)e^{2ik^2(x-y)}|u_y|^2\bar{u}_ydy.$$

We can estimate $m_2(x, k)$ as before except for $m_1(x, k)$, $s_1(x, k)$ and $s_2(x, k)$, to estimate which we integrate by parts to obtain

$$m_1(x, k) = \frac{i}{4k^2} \int_x^\infty (1 + 2ik^2(y - x)^2)\bar{u}_y(x)e^{2ik^2(x-y)}dy,$$

$$s_1(x, k) = -\frac{i}{k} \int_x^\infty ((x - y)\bar{u}_{yy} - \bar{u}_{yy})e^{2ik^2(x-y)}dy,$$

$$s_2(x, k) = \frac{1}{2k} \int_x^\infty e^{2ik^2(x-y)}(|u_y| - (x - y)|u_y|^2\bar{u}_{yy} + 2(x - y)|u_y|\bar{u}_{yy}|u_y|_y)dy.$$
Obviously, we can use the previous techniques to bound \( m_1(x, k), s_1(x, k) \) and \( s_2(x, k) \) for \( I_\infty \).

Finally we elaborate on the mapping properties of the operators \( T \) and \( T_k \).

**Lemma 6.** For large \(|k| > 1\), we have the following estimates

\[
\| T \|_{L^2(\mathbb{R}^+ \times I_\infty) \to L^2(\mathbb{R}^+ \times I_\infty)} \lesssim \| \tilde{u} \|_{L^2} \| u \|_{H^1},
\]

(2.55)

\[
\| T \|_{L^2(\mathbb{R}^+ \times I_\infty) \to C^0(\mathbb{R}^+, L^2(I_\infty))} \lesssim \| \tilde{u} \|_{L^2} \| u \|_{H^1},
\]

(2.56)

\[
\| T_k \|_{L^2(\mathbb{R}^+ \times I_\infty) \to L^2(\mathbb{R}^+ \times I_\infty)} \lesssim \| \tilde{u}_x \|_{L^2} \| u \|_{H^2},
\]

(2.57)

\[
\| T_k \|_{L^2(\mathbb{R}^+ \times I_\infty) \to C^0(\mathbb{R}^+, L^2(I_\infty))} \lesssim \| \tilde{u}_x \|_{L^2} \| u \|_{H^2},
\]

(2.58)

**Proof.** We prove (2.57) and (2.58). The operator \( T \) defined in (2.45) has the integral kernel

\[
K_+(x, y, k) = \begin{cases} 
\int_y^\infty e^{2i(k_y^2(y-z))\tilde{u}_z(z)dz} \tilde{u}(y), & x < y, \\
0 & x > y.
\end{cases}
\]

(2.59)

From this computation, we have

\[
(Tf)^*(x) \leq \left( \| \tilde{u}_x \|_{L^1} \int_x^\infty |\tilde{u}(y)| dy \right) f^*(x).
\]

(2.60)

From the formula

\[
\frac{\partial T}{\partial k}[h](x, k) = \frac{i}{2} \int_x^\infty \tilde{u}_y(y) \int_y^\infty 4ik(y-z)e^{2ik^2(y-z)}\tilde{u}(z)h(z, k)dzdy
\]

(2.61)

Then we estimate

\[
\left| \frac{\partial T}{\partial k}[h](x, k) \right| \lesssim \| \tilde{u}_x \|_{L^2} \| h(\cdot, k) \|_{H^1} \int_x^\infty |u_y(y)| dy,
\]

(2.62)

with \( \| h(\cdot, k) \|_{H^1} = 1 \). From which we conclude that

\[
\left\| \frac{\partial T}{\partial k} \right\|_{C^0(\mathbb{R}^+, L^2(I_\infty))} \lesssim \| \tilde{u}_x \|_{L^2} \| u \|_{H^1},
\]

(2.63)

\[
\left\| \frac{\partial T}{\partial k} \right\|_{L^2(\mathbb{R}^+ \times I_\infty)} \lesssim \| \tilde{u}_x \|_{L^2} \| u \|_{H^2}.
\]

(2.64)
B. Resolvent Estimates.

As an analogy to the above deduction, we utilize Volterra estimates to construct the resolvent, from which an integral kernel is obtained. Finally, we extend the resolvent to a bounded operator on the spaces \( C^0(\mathbb{R}^+, L^2(I_\infty)) \) and \( L^2(\mathbb{R}^+ \times I_\infty) \).

**Lemma 7.** We suppose that \( u(x,0) \in H^{3,3}(\mathbb{R}) \). The resolvent \((I-T)^{-1}\) exists as a bounded operator in \( C^0(\mathbb{R}^+) \) and the operator \( L \equiv (I-T)^{-1} - I \) is an integral operator with an integral kernel \( L(x,y,k) \) such that \( L(x,y,k) = 0 \) for \( x>y \), continuous in \((x,y,k)\) for \( x<y \), and obeys the estimates

\[
|L(x,y,k)| \leq \exp \left( \|u\|_{W^{1,1}} \|\tilde{u}\|_{L_1} \right) \|u\|_{w^{1,1}} |\tilde{u}(y)|. \tag{2.65}
\]

**Proof.** The rest of the proof is parallel to the proof of Lemma 4. \( \square \)

According to the above analysis, we can estimate \( \eta_{11,k} \).

**Proposition 3.** Suppose that \( u(x,0) \in H^{3,3}(\mathbb{R}) \) and \( k \in I_\infty \), the the equation \((2.46)\) admits a unique solution \( \eta_{11} \in C^0(\mathbb{R}^+, L^2(I_\infty)) \cap L^2(\mathbb{R}^+ \times I_\infty) \). Moreover,

(i) \( u(x,0) \rightarrow \eta_{11}(x,k) \) is Lipschitz continuous as a map from \( H^{3,3}(\mathbb{R}) \) to \( C^0(\mathbb{R}^+, L^2(I_\infty)) \cap L^2(\mathbb{R}^+ \times I_\infty) \).

(ii) \( u(x,0) \rightarrow \eta_{11,k}(x,k) \) is Lipschitz continuous as a map from \( H^{3,3}(\mathbb{R}) \) to \( C^0(\mathbb{R}^+, L^2(I_\infty)) \cap L^2(\mathbb{R}^+ \times I_\infty) \).

2.2 Symmetries and asymptotics of eigenfunctions

According to the Lax pair \((2.1)\) and the transformation in \((2.3)\), there exists a matrix function \( S(k) \) such that

\[
\omega^-(x,k) = \omega^+(x,k)e^{-ik^2x\tilde{\sigma}_3}S(k). \tag{2.66}
\]

Below, we characterize the symmetry properties of \( \omega^\pm(x,k) \).

**Proposition 4.** \( \omega^\pm(x,k) \) and \( S(k) \) satisfy the symmetry relations

\[
\begin{align*}
\omega^\pm(x,k) &= \sigma_2\omega^\pm(x,-k)\sigma_2, & \omega^\pm(x,k) &= \sigma_3\omega^\pm(x,-k)\sigma_3, \\
S(k) &= \sigma_2S(-k)\sigma_2, & S(k) &= \sigma_3S(-k)\sigma_3,
\end{align*}
\]  \tag{2.67, 2.68}

where

\[
\sigma_2 = \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}, \quad \sigma_3 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}.
\]
From the symmetries (2.68), \( S(k) \) admits the form

\[
S(k) = \begin{pmatrix}
    a(k) & b(k) \\
    -b(k) & a(k)
\end{pmatrix},
\]

(2.69)

where \( a(k) \) and \( b(k) \) are given by solving (2.66), i.e.,

\[
a(k) = \det(\omega_1^- , \omega_2^- ) = \omega_{11}^-(0,k)\omega_{11}^+(0,k) - \omega_{21}^-(0,k)\omega_{21}^+(0,k),
\]

(2.70)

\[
b(k) = \det(\omega_2^- , \omega_2^- ) = \omega_{21}^-(0,k)\omega_{11}^+(0,k) - \omega_{21}^+(0,k)\omega_{21}^-(0,k),
\]

(2.71)

where we denote the matrix eigenfunctions \( \omega^\pm(x,k) = (\omega_{ij}(x,k))_{2 \times 2} \). In terms of the solutions \( \eta_{11}^\pm \) and \( \eta_{21}^\pm \), the functions \( a(k) \) and \( b(k) \) defined in (2.70) and (2.71) are expressed as

\[
a(k) - 1 = a_1(k) + a_2(k), \quad b(k) = b_1(k) + b_2(k),
\]

(2.72)

where

\[
a_1(k) = \eta_{11}^+(0,k) + \eta_{11}^-(0,k) + \eta_{11}^+(0,k),
\]

\[
a_2(k) = \frac{1}{4k^2} |u_x(0)|^2 + \frac{i}{2k} u_x(0) \eta_{21}^+(0,k) - \frac{i}{2k} u_x(0) \eta_{21}^-(0,k) + \eta_{21}^-(0,k) \eta_{21}^+(0,k),
\]

and

\[
b_1(k) = \left( -\eta_{21}^+(0,k) + \frac{i}{2k} u_x(0) \eta_{21}^+(0,k) \right) + \left( \eta_{21}^-(0,k) - \frac{i}{2k} u_x(0) \eta_{21}^+(0,k) \right),
\]

\[
b_2(k) = \eta_{11}^+(0,k) \eta_{21}^+(0,k) - \eta_{11}^-(0,k) \eta_{21}^+(0,k).
\]

To prove that \( u(x,0) \to kr(k) \) is Lipschitz continuous from \( H^{3,3}(\mathbb{R}) \) to \( L^2(I_\infty) \), it suffices to show that \( u(x,0) \to kb(k) \) has the same Lipschitz continuity.

**Proposition 5.** Suppose that \( u(x,0) \in H^{3,3}(\mathbb{R}) \), then \( u(x,0) \to kb(k) \) is Lipschitz from \( H^{3,3}(\mathbb{R}) \) to \( L^2(I_\infty) \).

**Proof.** Here we give the proof of the case \( k \in \mathbb{R} \), which the case \( k \in i\mathbb{R} \) is analogous. We rewrite (2.42) as

\[
\eta_{21}^\pm = \frac{i}{2k} u_x \eta_{11}^\pm - \frac{i}{2k} \int_x^{\pm \infty} e^{2ik(x-y)/\sigma} \bar{u}(y) \left( 1 + \eta_{11}^\pm \right) dy.
\]

(2.73)

Setting \( x = 0 \), (2.73) becomes

\[
\eta_{21}^\pm (0,k) + \frac{i}{2k} u_x (0) \eta_{11}^\pm (0,k) = Q^\pm,
\]

(2.74)
with
\[ Q^\pm = -\frac{i}{2k} \int_0^{\pm\infty} e^{-2ik^2y} \tilde{u}(y) \left( 1 + \eta^\pm_{11} \right) dy. \] (2.75)

And for \( kb(k) \), it is in a new form as
\[ kb(k) = Q^+(k) + Q^-(k) - \eta_{11}(0,k)Q^+(k) + \eta_{11}(0,k)Q^-(k). \] (2.76)

According to the following estimate
\[ \| Q^\pm \|_{L^2(I, \infty)} \leq \| \tilde{u} \|_{L^2(\mathbb{R})} \left( 1 + \| \eta_{11}^\pm \|_{L^2(\mathbb{R}^\pm \times I, \infty)} \right), \] (2.77)

it suffices to show that \( u(x,0) \to Q^\pm(k) \) is Lipschitz from \( H^{\frac{3}{2},2}(\mathbb{R}) \) to \( L^2(I, \infty) \), from which we obtain \( u(x,0) \to kb(k) \) is Lipschitz from \( H^{\frac{3}{2},2}(\mathbb{R}) \) to \( L^2(I, \infty) \).

**Lemma 8.** The \( \omega^\pm(x,k) \) admit the asymptotics
\[ \omega^\pm(x,k) \sim I, \quad \text{as} \quad k \to \infty, \] (2.78)
\[ \omega^\pm(x,k) \sim \varphi(x), \quad \text{as} \quad k \to 0. \] (2.79)

The \( a(k) \) and \( b(k) \) admit the asymptotics
\[ a(k) = 1 + \mathcal{O}(k^{-1}), \quad b(k) = \mathcal{O}(k^{-1}), \quad \text{as} \quad k \to \infty, \] (2.80)
\[ a(k) = e^{-\frac{i}{2}d_0 \sigma_3} \left( 1 + \mathcal{O}(k^3) \right), \quad b(k) = \mathcal{O}(k^3), \quad \text{as} \quad k \to 0, \] (2.81)

where
\[ d_0 = \int_{-\infty}^{+\infty} |u_y|^2(y,t) \, dy. \] (2.82)

**Proof.** The asymptotics (2.80) can be obtained by using (2.70)-(2.71). The \( \omega^\pm(x,k) \) and the spectral data \( a(k), b(k) \) have the asymptotics at \( k = 0 \) [37].

### 2.3 Scattering map from initial data to scattering coefficients

First, we define the reflection coefficient
\[ r(k) = \frac{b(k)}{a(k)}. \] (2.83)

From \( \det S(k) = 1 \), by using the symmetry (2.67), we obtain
\[ 1 + |r(k)|^2 = \frac{1}{|a(k)|^2}, \quad k \in \mathbb{R}, \]
\[ 1 - |r(k)|^2 = \frac{1}{|a(k)|^2}, \quad k \in i\mathbb{R}. \]
In the absence of spectral singularities, there also exists a $c \in (0, 1)$ such that $c < |a(k)| < 1/c$ for $k \in \Sigma = \mathbb{R} \cup i\mathbb{R}$. To cope with the following derivation, we assume our initial data satisfies the assumption below.

**Assumption 1.** The initial data $u(x, 0) \in H^{3,3}(\mathbb{R})$ generates generic scattering data that satisfies

1. $a(k)$ has no zeros on $\Sigma$,
2. $a(k)$ only has a finite number of simple zeros.

Combining the above results, we immediately obtain the following theorem on $r(k)$.

**Theorem 1.** For any given $u(x, 0) \in H^{3,3}(\mathbb{R})$, we have $r(k) \in H^{1,1}(\Sigma)$.

**Proof.** By using (2.80)-(2.81) and Definition (2.83), we have

$$r(k) = O(k^3), \ k \to 0, \quad r(k) = O(k^{-1}), \ k \to \infty.$$  

Again $a(k)$ has no zeros on $\Sigma$ by Assumption 1 above, we conclude that $r(k)$ has no spectral singularities on the contour $\Sigma$.

Combining (2.70)-(2.71), Proposition 2 and 3, we derive that

$$a(k), b(k) \in L^\infty(\Sigma) \cap L^2(\Sigma),$$

by definition (2.83), we then have

$$r(k) \in L^2(\Sigma). \quad (2.84)$$

Noting that

$$a'(k) = \det(\omega_{1,k}^-, \omega_2^+) + \det(\omega_1^-, \omega_{2,k}^+), \quad (2.85)$$
$$b'(k) = \det(\omega_{2,k}^-, \omega_2^+) + \det(\omega_2^-, \omega_{2,k}^+), \quad (2.86)$$

by Proposition 2 and 3, we obtain that $a'(k), b'(k) \in L^2(\Sigma)$. So we have

$$r'(k) = \frac{b'(k)a(k) - a'(k)b(k)}{a^2(k)} \in L^2(\Sigma), \quad (2.87)$$

which, combined with (2.84) and Proposition 5, finally gives the map $u(x, 0) \to r(k)$ is Lipschitz continuous from $H^{3,3}(\mathbb{R})$ into $H^{1,1}(\Sigma)$. \qed
3 Construction of the RH problem

Since \( a(k) \) is an even function, each zero \( k_j \) of \( a(k) \) is accompanied by another zero at \(-k_j\). We assume that \( a(k) \) has \( 2N \) simple zeros \( \{k_j\}_{j=1}^{2N} \subset D^+ \) such that \( \{k_j\}_{j=1}^{N} \) belong to the first quadrant and \( k_{j+N} = -k_j, j = 1, \ldots N \). Similarly, \( a(k) \) has \( 2N \) simple zeros \( \{\overline{k}_j\}_{j=1}^{2N} \subset D^- \) such that \( \{\overline{k}_j\}_{j=1}^{N} \) belong to the second quadrant and \( \overline{k}_{j+N} = -\overline{k}_j, j = 1, \ldots N \). They can be denoted by

\[
\mathcal{K} = \{k_j, j = 1, \ldots, 2N\} \subset D^+, \quad \overline{\mathcal{K}} = \{\overline{k}_j, j = 1, \ldots, 2N\} \subset D^-.
\]

We define a sectionally meromorphic matrix

\[
M(k;x,t) = \begin{cases} 
\frac{\omega^{-}_1(k;x,t)}{a(k)}, \omega^{-}_2(k;x,t), & k \in D^+,
\omega^{-}_1(k;x,t), \frac{\omega^{-}_2(k;x,t)}{a(k)}, & k \in D^-,
\end{cases}
\]

which solves the following RH problem.

**RH Problem 3.1.** Find a matrix-valued function \( M(k) = M(k;x,t) \) which satisfies:

(a) **Analyticity:** \( M(k) \) is meromorphic in \( \mathbb{C} \setminus \Sigma \) and has single poles;

(b) **Symmetry:** \( \overline{M(k)} = \sigma_2 M(k) \sigma_2 \);

(c) **Jump condition:** \( M(k) \) has continuous boundary values \( M_\pm \) on \( \Sigma \) and

\[
M_+(k) = M_-(k)V(k), \quad k \in \Sigma,
\]

where

\[
V(k) = \left( \frac{1 + r(k)r(k)}{r(k)e^{-2i\theta(k)}} \right) \overline{r(k)e^{-2i\theta(k)}} \left( \frac{r(k)e^{-2i\theta(k)}}{1} \right);
\]

(d) **Asymptotic behaviors:**

\[
\begin{align*}
M(k) &= I + \mathcal{O}\left(k^{-1}\right), \quad k \to \infty, \\
M(k) &= e^{-2\sigma_3} \left( I + kU + \mathcal{O}\left(k^2\right) \right) e^{2\sigma_3}, \quad k \to 0;
\end{align*}
\]

(e) **Residue conditions:** \( M \) has simple poles at each point in \( \mathcal{K} \) and \( \overline{\mathcal{K}} \) with:

\[
\text{Res}_{k=k_j} M(k) = \lim_{k \to k_j} M(k)R(k_j),
\]

\[
\text{Res}_{k=\overline{k}_j} M(k) = \lim_{k \to \overline{k}_j} M(k)\sigma_2 R(k_j)\sigma_2,
\]

where \( R(k_j) \) is the nilpotent matrix

\[
R(k_j) = \begin{pmatrix} 0 & 0 \\ 0 & 0 \end{pmatrix}.
\]
and \( \theta(k) = k^2 \frac{\pi}{2} + \eta^2(k), \eta(k) = \sqrt{\alpha(k - \frac{\pi}{4})} \). Intuitively, the contour, poles and the stationary phase points of \( M(k) \) are illustrated in Figure 2.

![Figure 2: The RH problem for \( M(k) \), where the jump contour \( \Sigma = \mathbb{R} \cup i\mathbb{R} \), the red dots (•) represent the poles, and the blue dots (•) represent the stationary phase points.](image)

We denote the norming constant \( c_j = c(k_j) = b(k_j)/a'(k_j) \) and the collection \( S = \{k_j, c_j\}_{j=1}^{2N} \) is called the scattering data. The solution of the FL equation (1.2) can be expressed by

\[
    u_x(x,t) = m(x,t)e^{-i \int_{-\infty}^{x} |m(x',t)|^2 dx'},
\]

(3.7)

where

\[
    m(x,t) = 2i \lim_{k \to \infty} \text{Re}(kM(x,t,k))_{12},
\]

(3.8)

we have

\[
    |u_x(x,t)| = 4|m(x,t)|.
\]

(3.9)

\section{Existence and uniqueness of solution to the RH problem}

In this section, we prove the existence and uniqueness of solution for the initial value problem (1.2)-(1.3). We first transform the basic RH Problem 3.1 to an equivalent RH problem—RH Problem 4.1, whose existence and uniqueness are affirmed by proving that the associated Beals-Coifman initial integral equation admits a unique solution for \( r(k) \in H^{1,1}(\Sigma) \). We further show that the solution \( M(k) \) of the RH Problem 3.1 obeys the Lax
pair (2.1) as a function of $x$ and $t$, and give reconstruction formulas for $u(x, t)$ in terms of the solution $\mu(x, k)$ of the Beals-Coifman initial integral equation.

To replace the residue conditions (3.5)-(3.6) of the RH Problem 3.1 with Schwartz invariant jump conditions, for all poles $k_j \in \mathbb{D}^+$ and $\bar{k}_j \in \mathbb{D}^-$, we trade their residues into the corresponding jumps on circles $\gamma_j$ centered at $k_j$ and $\bar{\gamma}_j$ centered at $\bar{k}_j$ respectively. The radii of these circles are chosen sufficiently small such that they are disjoint from all other circles. Please see Figure 3.

![Figure 3: The jump contour $\Sigma'$ of RH problem for $M(k)$.

Let

$$\Sigma' = \Sigma \cup \{\gamma_j\}_{j=1}^{2N} \cup \{\bar{\gamma}_j\}_{j=1}^{2N},$$

we then transform the RH Problem 3.1 to an equivalent RH problem (for simplicity, we still use the notation $M(k; x, t)$) on the jump contour $\Sigma'$.

**RH Problem 4.1.** Find a matrix-valued function $M(k) = M(k; x, t)$ which satisfies

(a) **Analyticity:** $M(k; x, t)$ is analytic in $\mathbb{C}\setminus \Sigma'$;

(b) **Jump condition:** $M(k; x, t)$ has continuous boundary values $M_{\pm}(k; x, t)$ on $\Sigma'$ and

$$M_+(k; x, t) = M_-(k; x, t)J(k),$$

(4.1)

22
where

\[
J(k) = \begin{cases} 
1 + |r(k)|^2 & \frac{r(k)e^{-2ik\theta(k)}}{r(k)e^{2ik\theta(k)}}, \quad k \in \mathbb{R}, \\
1 - |r(k)|^2 & \frac{-r(k)e^{-2ik\theta(k)}}{r(k)e^{2ik\theta(k)}}, \quad k \in i\mathbb{R}, \\
1 & \frac{1}{\epsilon_{j}e^{2ik\theta(k)}}, \quad k \in \gamma_j \\
0 & \frac{1}{k-k_{j}} \end{cases}
\]

(c) Asymptotic behaviors:

\[
\begin{cases} 
M(k) = I + \mathcal{O}(k^{-1}), \\
M(k) = e^{-\frac{i}{2}e^{-\sigma_{3}}(I + kU + \mathcal{O}(k^{2}))}e^{\frac{i}{2}d_{0}\sigma_{3}}, \quad k \to 0.
\end{cases} \tag{4.6}
\]

We suppress the dependence of all quantities on \(t\) to emphasize the role of \(x\) (later \(x,t\)).

To study the existence and the uniqueness of the solution to the RH Problem 4.1, we need the following RH problem with the jump contour \(\Sigma'\).

**RH Problem 4.2.** Find a matrix-valued function \(M(k; x)\) with the following properties:

(a) Analyticity: \(M(k; x)\) is analytic in \(\mathbb{C}\setminus\Sigma'\).

(b) Jump condition: \(M(k; x)\) has continuous boundary values \(M_{\pm}(k; x)\) on \(\Sigma'\) and

\[
M_+(x, k) = M_-(x, k)J(k), \quad k \to \infty,
\]

where

\[
J(k) = \begin{cases} 
1 + |r(k)|^2 & \frac{r(k)e^{-2ik^2x}}{r(k)e^{2ik^2x}}, \quad k \in \mathbb{R}, \\
1 - |r(k)|^2 & \frac{-r(k)e^{-2ik^2x}}{r(k)e^{2ik^2x}}, \quad k \in i\mathbb{R}, \\
1 & \frac{1}{\epsilon_{j}e^{2ik^2x}} \quad k \in \gamma_j \\
0 & \frac{1}{k-k_{j}} \end{cases}
\]

(c) Normalization

**Type I.** \(M(k; x) = I + \mathcal{O}(k^{-1})\) as \(k \to \infty\),
Type II. \( M(k; x) = \mathcal{O}(k^{-1}) \) as \( k \to \infty \),

where Type I with inhomogeneous boundary condition is needed for the reconstruction of the potential \( u_x(x) \). Type II is used to show the existence and uniqueness of the solution of the RH Problem 4.2 with Type I.

### 4.1 Beals-Coifman integral equation

The unique solvability of the RH Problem 4.2 is equivalent to the unique solvability of Beals-Coifman integral equation. We decompose the jump matrix (4.7) as

\[
J(k) = (I - w_-)^{-1}(I + w_+),
\]

and let

\[
\mu = M_+ (I + w_+)^{-1} = M_- (I - w_-)^{-1},
\]

from which we can write down \( \mu \) explicitly: For \( k \in \Sigma \)

\[
\mu(x, k) = \begin{cases} 
\left( \frac{\omega_1^{-1}(x, k)}{a(k)} \omega_2^+(x, k) \right) & \begin{pmatrix} 1 \\
1 & e^{2ik^2x}r(k) \end{pmatrix}, \\
\left( \frac{\omega_1^+(x, k)}{a(k)} \omega_2^+(x, k) \right) & \begin{pmatrix} 1 \\
1 & e^{-2ik^2x}r(k) \end{pmatrix},
\end{cases}
\]

(4.14)

and for \( k \in \gamma_j \)

\[
\mu(x, k) = \begin{cases} 
\left( \frac{\omega_1^{-1}(x, k)}{a(k)} \omega_2^+(x, k) \right) & \begin{pmatrix} 1 \\
1 & e^{2ik^2x} \omega_1^+(x, k) \end{pmatrix}, \\
\left( \frac{\omega_1^{-1}(x, k)}{a(k)} \omega_2^+(x, k) \right) & \begin{pmatrix} 1 \\
1 & e^{-2ik^2x} \omega_1^+(x, k) \end{pmatrix},
\end{cases}
\]

(4.15)

and for \( k \in \mathbb{C}_j \)

\[
\mu(x, k) = \begin{cases} 
\left( \frac{\omega_1^{-1}(x, k)}{a(k)} \omega_2^+(x, k) \right) & \begin{pmatrix} 1 \\
1 & \tilde{e} e^{-2ik^2x} \omega_1^+(x, k) \end{pmatrix}, \\
\left( \frac{\omega_1^{-1}(x, k)}{a(k)} \omega_2^+(x, k) \right) & \begin{pmatrix} 1 \\
1 & \tilde{e} e^{-2ik^2x} \omega_1^+(x, k) \end{pmatrix},
\end{cases}
\]

(4.16)

From (4.13), we obtain

\[
M_+ - M_- = \mu(w_+ + w_-),
\]

24
then Plenelj formula gives the following Beals-Coifman integral equation for Type I normalization in RH Problem 4.2

\[ \mu = I + C_{w\mu} = I + C_{\Sigma^+}^\pm (\mu w^-) + C_{\Sigma^+}^- (\mu w^+) , \]  

where \( I \) is the \( 2 \times 2 \) identity matrix. And for Type II normalization:

\[ \mu = C_{w\mu} = C_{\Sigma^+}^+ (\mu w^+) + C_{\Sigma^+}^- (\mu w^+) . \]  

In Type I, for \( k \in \Sigma , \)

\[
\mu_{11}(x, k) = 1 + \frac{1}{2\pi i} \int_{\mathbb{R}} \frac{\mu_{12}(x, s) r(s) e^{2i\pi s x}}{s - k + i0} ds + \frac{1}{2\pi i} \int_{\mathbb{R}} \frac{\mu_{12}(x, s) t(s) e^{2i\pi s x}}{s - k + \pi i} ds + \sum_{j=1}^{2N} \frac{\mu_{12}(x, \bar{k}_j)c_j e^{2i\pi k_j x}}{k - k_j},
\]

\[
\mu_{12}(x, k) = \frac{1}{2\pi i} \int_{\mathbb{R}} \frac{\mu_{11}(x, s) \tilde{r}(s) e^{2i\pi s x}}{s - k + i0} ds + \frac{1}{2\pi i} \int_{\mathbb{R}} \frac{\mu_{11}(x, s) \tilde{t}(s) e^{2i\pi s x}}{s - k + \pi i} ds - \sum_{i=1}^{2N} \mu_{11}(x, \bar{k}_i) \tilde{c}_i e^{-2i\pi k_i x}.
\]

\[
\mu_{21}(x, k) = \frac{1}{2\pi i} \int_{\mathbb{R}} \frac{\mu_{22}(x, s) r(s) e^{2i\pi s x}}{s - k + i0} ds + \frac{1}{2\pi i} \int_{\mathbb{R}} \frac{\mu_{22}(x, s) t(s) e^{2i\pi s x}}{s - k + \pi i} ds + \sum_{i=1}^{2N} \frac{\mu_{22}(x, k_i)c_j e^{2i\pi k_j x}}{k - k_j},
\]

\[
\mu_{22}(x, k) = 1 + \frac{1}{2\pi i} \int_{\mathbb{R}} \frac{\mu_{21}(x, s) \tilde{r}(s) e^{2i\pi s x}}{s - k + i0} ds + \frac{1}{2\pi i} \int_{\mathbb{R}} \frac{\mu_{21}(x, s) \tilde{t}(s) e^{2i\pi s x}}{s - k + \pi i} ds - \sum_{i=1}^{2N} \mu_{21}(x, \bar{k}_i) \tilde{c}_i e^{2i\pi k_i x}.
\]

and in order to close the system, we have

\[
\mu_{11}(x, \bar{k}_j) = 1 + \frac{1}{2\pi i} \int_{\Sigma} \frac{\mu_{12}(x, s) r(s) e^{2i\pi s x}}{s - k_j} ds + \sum_{i=1}^{2N} \frac{\mu_{12}(x, k_i)c_i e^{2i\pi k_j x}}{k_i - k_j},
\]

\[
\mu_{12}(x, k_j) = \frac{1}{2\pi i} \int_{\Sigma} \frac{\mu_{11}(x, s) \tilde{r}(s) e^{-2i\pi s x}}{s - k_j} ds - \sum_{i=1}^{2N} \frac{\mu_{11}(x, \bar{k}_i) \tilde{c}_i e^{-2i\pi k_i x}}{k_j - k_i},
\]

\[
\mu_{21}(x, \bar{k}_j) = \frac{1}{2\pi i} \int_{\Sigma} \frac{\mu_{22}(x, s) r(s) e^{-2i\pi s x}}{s + k_j} ds + \sum_{i=1}^{2N} \frac{\mu_{22}(x, k_i)c_i e^{2i\pi k_j x}}{k_j - k_i},
\]

\[
\mu_{22}(x, k_j) = 1 + \frac{1}{2\pi i} \int_{\Sigma} \frac{\mu_{21}(x, s) \tilde{r}(s) e^{-2i\pi s x}}{s - k_j} ds - \sum_{i=1}^{2N} \mu_{21}(x, \bar{k}_i) \tilde{c}_i e^{-2i\pi k_i x}.
\]

Finally, we obtain

\[ u_x(x) = -\frac{1}{\pi} \int_{\Sigma} e^{-2i\pi k^2 x} \tilde{r}(k) \mu_{11}(x, k) dk - \sum_{j=1}^{2N} 2i \mu_{11}(x, \bar{k}_j) \tilde{c}_j e^{-2i\pi k_j x}. \]  

4.2 Application of Zhou’s vanishing lemma

It is found that the matrix \( J(k) \) in (4.8) is Hermitian for \( k \in \mathbb{R} \). In this case, we can use Zhou’s Vanishing Lemma from [39] to obtain a unique solution of the RH Problem
4.2. Though the matrices (4.9)-(4.11) are not Hermitian for $k \in i\mathbb{R}$ and $k \in \gamma_j$, $\bar{\gamma}_j$, their jump contours are oriented to preserve Schwartz reflection symmetry in the real axis $\mathbb{R}$, and the matrix-valued function $F(k) = M(k)M(\bar{k})^H$ is still analytic for $k \in \mathbb{C}\setminus\mathbb{R}$. This indeed fits into the framework of Zhou’s Vanishing Lemma and obtain the same conclusion in the following Proposition.

**Proposition 6.** The solution to the RH Problem 4.2 with Type II normalization is identically zero.

**Proof.** We first recall that the symmetry reduction condition for the entries of the transition matrix is given as follows: for $k \in i\mathbb{R}$, $r(\bar{k}) = r(-k) = -r(k)$. So we conclude from (4.9) that

$$J(k) = J(\bar{k})^H, \quad k \in i\mathbb{R},$$

(4.20)

where $^H$ denotes the complex conjugation and transpose of a given matrix. From (4.10) and (4.11), it is easy to check that the same equality holds on $\{\gamma_j \cup \bar{\gamma}_j\}_{j=1}^{2N}$. So we conclude that (4.20) holds on $\Sigma'\setminus\mathbb{R}$.

Now we formulate the matrix-valued function

$$F(k) = M(k)M(\bar{k})^H$$

(4.21)

and we want to show that

$$\int_{\mathbb{R}} F_\pm(k)dk = 0.$$ 

(4.22)

It is clear that $F(k)$ is analytic in $\mathbb{C}\setminus\Sigma'$ by the Schwartz reflection principle. For $k \in \mathbb{C}\setminus\mathbb{R}$, we then have

$$F_+(k) = M_+(k)M_-(\bar{k})^H = M_-(k)J(k)\left(J(\bar{k})^{-1}\right)^HM_+(\bar{k})^H$$

$$= M_-(k)M_+(\bar{k})^H = F_-(k).$$

By Morera’s theorem $F(k)$ is analytic for $k \in \mathbb{C}\setminus\mathbb{R}$. Since $M_\pm(x, \cdot) \in L^2(\mathbb{R})$, $F(k)$ is integrable. By the Beal-Coifman theorem, we can write

$$M(x, k) = \frac{1}{2\pi i} \int_{\Sigma'} \frac{\mu(x, s) (w_+(s) + w_-(s))}{s - k} ds$$

$$= \frac{1}{2k\pi i} \int_{\Sigma'} \frac{s}{s - k} \mu(x, s) (w_+(s) + w_-(s)) ds - \frac{1}{2k\pi i} \int_{\Sigma'} \mu(x, s) (w_+(s) + w_-(s)) ds,$$

which implies that

$$M(x, k) \sim O(k^{-1}), \quad k \in \mathbb{C}\setminus\mathbb{R},$$

26
and \( F(k) \sim \mathcal{O}(k^{-2}) \), \( k \in \mathbb{C} \setminus \mathbb{R} \) by the definition (4.21). Then the equality (4.22) follows from Jordan theorem and Cauchy integral theorem.

For \( k \in \mathbb{R} \), we have that
\[
F_+(k) = M_+(k)M_-(k)^H = M_-(k)J(k)M_-(k)^H,
\]
(4.23)
and
\[
F_-(k) = M_-(k)M_+(k)^H = M_-(k)J(k)^HM_-(k)^H,
\]
(4.24)
and from (4.22) we get
\[
\int_{\mathbb{R}} M_-(k) \left( J(k) + J(k)^H \right) M_-(k)^H = 0,
\]
(4.25)
where for \( k \in \mathbb{R} \),
\[
J(k) + J(k)^H = 2 \begin{pmatrix} 1 + |r(k)|^2 & r(k)e^{-2ikx} \\ r(k)e^{2ikx} & 1 \end{pmatrix}
\]
is positive definite since it is Hermitian and has positive eigenvalues. Thus from (4.25) we conclude that \( M_-(k) = 0 \) on \( \mathbb{R} \). Further we also have
\[
M_+(k) = M_-(k)J(k) = 0, \quad k \in \mathbb{R}.
\]
From Morera’s theorem we conclude that \( M(k) \) is analytic in a neighborhood of every point on \( \mathbb{R} \). Since \( M(k) = 0 \) for \( k \in \mathbb{R} \), the analytic continuation gives us that \( M(k) = 0 \) holds all the way up to the first complex part of \( \Sigma \). Applying the jump condition on this part shows that \( M_\pm(k) \) vanishes. We can apply the same argument to the remaining parts of \( \Sigma' \) and conclude that \( M(k) \equiv 0 \) on the entire complex plane.

The following proposition is a standard result from the Fredholm alternative theorem.

**Proposition 7.** Let the initial data \( u(x,0) \in H^{3,3}(\mathbb{R}) \), then the RH Problem 4.2 with Type I normalization has a unique solution \( M(k) \).

### 4.3 Reconstruction of the potential

In this part we show that the solution to the RH Problem 4.2 with Type I normalization solves the spatial spectral problem (2.10) and obtain explicit formulas for the potentials.

**Lemma 9.** Let
\[
f(x,k) = \mu(x,k) \left( w_+(k) + w_-(k) \right),
\]
(4.26)
then we have
\[ \int_{\Sigma'} s^n f(x,s) ds = \int_{\Sigma} s^n f(x,s) ds + \int_{\Sigma' \setminus \Sigma} s^n f(x,s) ds \]  
(4.27)
is diagonal when \( n \) is odd and off-diagonal when \( n \) is even.

**Proposition 8.** The functions \( M_\pm(k) \) obey the spatial spectral problem (2.10), where \( M(k) \) and \( U_x \) are constructed from the solution \( \mu(k) \) of the Beals-Coifman integral equation (4.17) as follows

\[
M(x,k) = I + \frac{1}{2\pi i} \int_{\Sigma'} \! \! \! \frac{\mu(x,s) (w_+(s) + w_-(s))}{s - k} ds,
\]  
(4.28)

\[
U_x(x) = -\frac{1}{\pi} \left[ \sigma_3, \left( \int_{\Sigma'} \! \! \! \mu_{11}(x,s) \tilde{r}(s) e^{-2is^2 x} ds \right) \right].
\]  
(4.29)

**Proof.** For \( k \in \Sigma' \), differentiating the jump relation (4.7) with respect to \( x \) leads to

\[
M_{+,x} = M_{-,x} J + M_- (-ik^2[\sigma_3, J])
= M_{-,x} J + M_- (-ik^2[\sigma_3, M_- M_+])
= M_{-,x} J + ik^2[\sigma_3, M_-] J - ik^2[\sigma_3, M_+].
\]  
(4.30)

We conclude that

\[
M_{+,x}(x,k) + ik^2[\sigma_3, M_+] = (M_{-,x}(x,k) + ik^2[\sigma_3, M_-]) J.
\]  
(4.31)

Using the fact

\[
M_\pm(x,k) - I = C^\pm [\mu(k,x,\cdot) (w_-(\cdot) + w_+(\cdot))],
\]  
(4.32)

we conclude that

\[
Ik^2[\sigma_3, M_\pm](x,k) = i \left[ \sigma_3, C^\pm (\cdot)^2 f(x,\cdot) \right] - \frac{k}{2\pi i} \int_{\Sigma'} f(x,s) ds - \frac{1}{2\pi i} \int_{\Sigma'} sf(x,s) ds
\],

where \( f(x,k) \) is given by (4.26). It follows from Lemma 9 that the matrix-valued integral \( \int_{\Sigma} kf(x,k) dk \) is a diagonal matrix. Hence,

\[
\left[ \sigma_3, \int_{\Sigma'} sf(x,s) ds \right] = 0.
\]  
(4.33)

Defining \( U_x \) by (4.29), we have

\[
Ik^2[\sigma_3, (M_\pm)(x,k)] = i \left[ \sigma_3, C^\pm (\cdot)^2 f(x,\cdot) \right] + kU_x(x).
\]  
(4.34)
Note that Cauchy projection is bounded on $L^2$ and $\mu_{11}(k) - 1 \in L^2$ for each fixed $x$. We can show that the first term defines an $L^2$ function of $k$ for each $x$. Next, we observe that, by (4.32),

$$kU_x(x)(M_{\pm} - I) = U_x(x)C^\pm[(\cdot)f(x, \cdot)] - U_x(x)R(x),$$  \hfill (4.35)

where $R(x)$ is given by

$$R(x) = \frac{1}{2\pi i} \int_{\Sigma'} \mu(x, k) (w_+ (k) + w_- (k)) \, dk$$  \hfill (4.36)

and the first right-hand term of (4.35) is an $L^2$ function of $k$ for each $x$.

Now define

$$W_{\pm} = M_{\pm, x} + ik^2[\sigma_3, M_{\pm}] - kU_x(x)M_{\pm}(x) - U_x(x)R(x)M_{\pm}(x).$$

By (4.32),(4.34),(4.35), and the identity

$$-kU_x(x)M_{\pm}(x) - U_x(x)R(x)M_{\pm}(x) = -kU_x(x) - kU_x(x)(M_{\pm} - I) - U_x(x)R(x) - U_x(x)R(x)(M_{\pm} - I),$$  \hfill (4.37)

it now follows that $(W_+, W_-) \in \partial C_{\Sigma} (L^2)$ for each fixed $x$. More explicitly,

$$W_{\pm} = C^\pm_x[f(x, \cdot)] + i[\sigma_x, C^\pm(\cdot)^2f(x, \cdot)] - U_x(x) \left[ C^\pm(\cdot)f(x, \cdot) \right] - U_x(x)R(x) \left[ C^\pm(\cdot)f(x, \cdot) \right].$$  \hfill (4.38)

Also,

$$W_+ = W_- J.$$  \hfill (4.39)

and we can check that $W(x, k)$ has the same residue condition in the complex plane as the RH Problem 4.2. It follows from Proposition 6 that $W_+ = W_- = 0$. \hfill \Box

5 Deformation of the RH Problem

5.1 Conjugation

In the jump matrix (3.3), the oscillatory terms are $e^{\pm it\theta(k)}$, where

$$\theta(k) = k^2 t + \eta^2(k).$$  \hfill (5.1)

It will be found that the long-time asymptotic of RH Problem 3.1 is affected by the growth and the decay of the exponential function $e^{\pm it\theta(k)}$ appearing in both the jump relation and
the residue conditions. In this section, we introduce a new transform \( M(k) \to M^{(1)}(k) \), from which we make \( M^{(1)}(k) \) well-behaved as \( t \to \infty \) along any characteristic line. Without loss of generality, we focus on the case \( t > 0 \) below, while the case \( t < 0 \) can be handled with the same approach (Appendix A).

Let \( \xi = \frac{x}{t} + \alpha > 0 \), from (5.1), we find four phase points of the function \( \theta(k) \)

\[
z_n = k_0 e^{\frac{(n-1)\xi}{2}}, \quad n = 1, 2, 3, 4,
\]

where \( |z_n| = k_0 = (\frac{\alpha \beta^2}{\pi \xi})^{1/4} \). We further rewrite (5.1) in the form

\[
\theta(k) = \frac{\alpha \beta^2}{4} \left( \frac{k^2}{k_0^2} + \frac{1}{k^2} \right) - \alpha \beta,
\]

which leads to

\[
\text{Re}(i\theta(k)) = -\frac{1}{4} \alpha \beta^2 \text{Im} k^2 \left( \frac{1}{k_0^2} - \frac{1}{|k|^2} \right).
\]

The sign signature of \( \text{Re}(i\theta(k)) \) determines the decay domains of the oscillatory term \( e^{i\theta(k)} \) with respect to \( t \to \infty \), as Figure 4 shows.

![Figure 4](image)

**Figure 4:** The decay domains of exponential oscillatory terms, where \( |e^{i\theta(k)}| \to 0 \) when \( t \to \infty \) in yellow-shaded regions, while in blank regions, \( |e^{-i\theta(k)}| \to 0 \) when \( t \to \infty \).

To facilitate the subsequent analysis in the remainder of this paper, we will uniformly deal with the four stationary phase points \( z_n, n = 1, 2, 3, 4 \). For this purpose, we introduce some notations. We first divide \( \Sigma \) into the following eight intervals near the four stationary
phase points $z_n, n = 1, 2, 3, 4$:

$$I_{n1} = (0, z_n), \quad I_{n2} = (z_n, +\infty), \quad n = 1, 2,$$

$$I_{n1} = (z_n, 0), \quad I_{n2} = (-\infty, z_n), \quad n = 3, 4.$$

$$I_+ = \bigcup_{n=1}^{4} I_{n2}, \quad I_- = \bigcup_{n=1}^{4} I_{n1},$$

which is illustrated in Figure 5.

The partition $\Delta^\pm_{k_0}$ for $k_0 \in \mathbb{R}_+$ is defined as follows:

$$\Delta^+_{k_0} = \{ j \in \{1, \ldots, 2N \} : \lvert k_j \rvert > k_0 \},$$

$$\Delta^-_{k_0} = \{ j \in \{1, \ldots, 2N \} : \lvert k_j \rvert < k_0 \},$$

which splits the residue coefficients $c_j e^{2i\theta(k_j)}$ into two sets.

We define

$$T(k) = \prod_{j \in \Delta^-_{k_0}} \left( \frac{k - \overline{k_j}}{k - k_j} \right) \delta(k), \quad (5.4)$$
where $\delta(k)$ is given by
\[
\delta(k) = \prod_{n=1,3} \left( \frac{k-z_n}{k} \right)^{i\nu(z_n)} e^{\chi_n(k)} \prod_{n=2,4} \left( \frac{k}{k-z_n} \right)^{i\nu(z_n)} e^{\chi_n(k)},
\] (5.5)
\[
\nu(z_n) = -\frac{1}{2\pi} \ln[1 + r(z_n)\overline{r(z_n)}], \quad n = 1, 2, 3, 4,
\]
\[
\chi_n(k) = \frac{1}{2\pi i} \int_0^{z_n} \ln \left( \frac{1 + r(k')\overline{r(k')}}{1 + r(z_n)\overline{r(z_n)}} \right) \frac{dk'}{k' - k}, \quad n = 1, 2, 3, 4.
\]

Among all the formulas above, we choose the principal branch of logarithm functions.

**Proposition 9.** The function defined by (5.4) has following properties:

(a) $T(k)$ is meromorphic in $\mathbb{C}\setminus I_-$, i.e., for each $j \in \Delta_{q_0}$, $T(k)$ has a simple pole at $k_j$ and $\overline{k}_j$ which belong to $\mathcal{K} \cup \overline{\mathcal{K}}$,

(b) For $k \in \mathbb{C}\setminus I_-$, $T(k) = 1/T(k)$,

(c) For $k \in I_-$, the boundary values $T_{\pm}(k)$ satisfy
\[
T_+(k)/T_-(k) = 1 + r(k)\overline{r(k)},
\] (5.6)

(d) $|k| \to \infty$ with $|\arg(k)| \leq c < \pi$
\[
T(k) = 1 + \frac{i}{k} \left[ 2 \sum_{j \in \Delta_{q_0}} \text{Im}(k_j) - \int_{I_-} k(s) ds \right] + \mathcal{O}(k^{-2}),
\] (5.7)

(e) $k \to z_n, \quad n = 1, 2, 3, 4$ along any ray $z_n + e^{i\phi}R_+$ with $|\phi| \leq c < \pi$
\[
|T(k) - T_0(z_n)(k-z_n)^{i\nu(z_n)}| \leq c|k-z_n|^{1/2},
\] (5.8)

where
\[
T_0(z_n) = \prod_{j \in \Delta_{q_0}} \left( \frac{z_n - \overline{k}_j}{z_n - k_j} \right)^{e^{i\beta(k,z_n)}},
\] (5.9)
\[
\beta(k,z_n) = -\nu(z_n) \log \left( k - z_n + e^{\frac{i(\nu(z_n))}{2}} \right) + \int_{I_-} \frac{\nu(s) - \chi_n(s)\nu(z_n)}{s - k} ds,
\] (5.10)

with $n = 1, 2, 3, 4$.

Using our partial transmission coefficient $T(k)$ defined above, we make a transformation
\[
M^{(1)}(k) = M(k)T(k)^{-\sigma_3},
\] (5.11)
which satisfies the following RH problem:

**RH Problem 5.1.** Find a matrix function \( M^{(1)}(k) = M^{(1)}(k; x, t) \) with the following properties:

(a) **Analyticity:** \( M^{(1)}(k) \) is meromorphic in \( \mathbb{C} \setminus \Sigma \);

(b) **Symmetry:** \( \overline{M^{(1)}(k)} = \sigma_2 M^{(1)}(k) \sigma_2 \);

(c) **Jump condition:** \( M^{(1)}(k) \) satisfies the jump condition

\[
M_+^{(1)}(k) = M_-^{(1)}(k) V^{(1)}(k),
\]

the jump matrix \( V^{(1)}(k) \) is defined by

\[
V^{(1)} = \begin{cases}
\left( \begin{array}{cc}
1 & 0 \\
0 & 1
\end{array} \right), & k \in I_-
\end{cases}
\]

\[
\left( \begin{array}{cc}
1 & 0 \\
0 & 1
\end{array} \right), & k \in I_+
\]

(d) **Asymptotic conditions:**

\[
\begin{align*}
M^{(1)}(k) &= I + \mathcal{O}(k^{-1}), & k \to \infty, \\
M^{(1)}(k) &= e^{-\frac{\pi}{2} \sigma_3 (I + kU + \mathcal{O}(k^2))} e^{\frac{i}{2} \text{diag} \sigma_3}, & k \to 0;
\end{align*}
\]

(e) **Residue conditions:** \( M^{(1)}(k) \) has simple poles at each \( k_j \in \mathcal{K} \cup \overline{\mathcal{K}} \) at which

\[
\begin{align*}
\text{Res} M^{(1)}_{k = k_j} &= \lim_{k \to k_j} M^{(1)}_R(k_j), & k \in \Delta^+_{k_0}, \\
\text{Res} M^{(1)}_{k = \overline{k}_j} &= \lim_{k \to \overline{k}_j} M^{(1)}_L(\overline{k}_j) \sigma_2, & k \in \Delta^+_{\overline{k}_0},
\end{align*}
\]

where

\[
R_-(k_j) = \begin{pmatrix}
0 & c_j^{-1}(1/T)'(k_j)^{-2} e^{-2it\theta(k_j)} \\
0 & 0
\end{pmatrix}, \quad R_+(k_j) = \begin{pmatrix}
0 & 0 \\
c_j T(k_j)^{-2} e^{2it\theta(k_j)} & 0
\end{pmatrix}.
\]

**Proof.** With Proposition 9 and the properties of \( M \), \( M^{(1)}(k) \) is unimodular, analytic in \( \mathbb{C} \setminus (\Sigma \cup \mathcal{K} \cup \overline{\mathcal{K}}) \), and approaches identity as \( k \to \infty \) by its definition. For the residues, since \( T(k) \) is analytic at each \( k_j, \overline{k}_j \) with \( k \in \Delta^\pm_{k_0} \), the residue conditions at these poles are an immediate consequence of (5.4). For \( k \in \Delta^\pm_{k_0}, T(k) \) has zeros at \( \overline{k}_j \), and poles at \( k_j \) so that \( M^{(1)}_R(k) = M_1(k) T(k)^{-1} \) has a removable singularity at \( k_j \) but acquires poles at \( \overline{k}_j \). For
\( M_2^{(1)}(k) = M_2(k)T(k) \) the situation is reversed where it has a pole at \( k_j \) and a removable singularity at \( \overline{k}_j \). At \( k_j \) we have

\[
M_1^{(1)}(k_j) = \text{Res}_{k=k_j} M_1(k)T(k)^{-1} = \text{Res}_{k=k_j} M_1(k) \cdot (1/T)'(k_j) \\
= c_j e^{2i\theta(k_j)} M_2(k_j)(1/T)'(k_j), \\
\text{Res}_{k=k_j} M_2^{(1)}(k) = \text{Res}_{k=k_j} M_2(k)T(k) = M_2(k_j)[(1/T)'(k_j)]^{-1} \\
= c_j^{-1} [(1/T)'(k_j)]^{-2} e^{-2i\theta(k_j)} M_1^{(1)}(k_j) .
\]

from which the first formula in (5.15) clearly follows. The computation of the residue at \( \overline{k}_j \) for \( k \in \Delta_{\overline{k}_0} \) can be calculated in the same way.

\( \square \)

### 5.2 A mixed ∂-RH problem

The main purpose of this section is to construct a new matrix function \( M^{(2)}(k) \) for deforming the contour \( \Sigma \) into a contour \( \Sigma^{(2)} \) such that: (i) \( M^{(2)}(k) \) has no jump on the real and the imaginary axis. For this purpose, we choose the boundary values of \( R^{(2)}(k) \) through the factorization of \( V^{(1)}(k) \) in (5.12) where the new jumps on \( \Sigma^{(2)} \) match a well-known model RH problem; (ii) We need to control the norm of \( R^{(2)}(k) \), so that the \( \overline{\partial} \)-contribution to the long-time asymptotics of \( u(x,t) \) can be ignored; (iii) The residues are unaffected by the transformation.

As Figure 6, we define a contour \( \Sigma^{(2)} = L \cup L_0 \cup \overline{L} \cup \overline{L}_0 \), where \( L = L_1 \cup L_2 \cup L_3 \cup L_4 \), and

\[
L_j = \{ k = z_j + ue^{\frac{3\pi i}{4}}, u \in (-\infty, \frac{1}{\sqrt{2}}] \}, \ j = 1, 4; \\
L_j = \{ k = z_j + ue^{-\frac{\pi i}{4}}, u \in (-\infty, \frac{1}{\sqrt{2}}] \}, \ j = 2, 3; \\
L_0 = \{ k = ue^{\frac{\pi i}{4}}, \ u \in [-\frac{1}{\sqrt{2}}, \frac{1}{\sqrt{2}}] \} .
\]
Figure 6: The jump contour $\Sigma^{(2)}$ for the $M^{(2)}$, which is consist of blue lines and red lines. The red lines decay along yellow domains; The blue lines decay along blank domains.

Furthermore, the contour $\Sigma^{(2)}$ contains $\Sigma_{ij}$ with $i = 0, 1, 2, 3, 4$ and $j = 1, 2, 3, 4$. $\Sigma$ and $\Sigma^{(2)}$ further divides the complex plane $\mathbb{C}$ into 24 sectors denoted by $D_{nj}$, where $n = 1, 2, 3, 4, 5, 6$ and $j = 1, 2, 3, 4$, which is plotted in Figure 7.
Figure 7: Jump contour $\Sigma^{(2)}$ and axis $\mathbb{R} \cup i\mathbb{R}$ divide the complex plane $\mathbb{C}$ into 16 domains on which we define the function $R^{(2)}$.

In addition, we define
$$\rho = \frac{1}{2} \min_{\lambda, \mu \in \mathcal{K} \cup \overline{\mathcal{K}}} |\lambda - \mu|.$$ (5.18)

Note that, as poles come in conjugate pairs and no pole lies on the real axis, we have $\rho \leq \text{dist}(\mathcal{K} \cup \overline{\mathcal{K}}, \Sigma)$. $\chi_K \in \mathcal{C}^\infty_0([0, 1])$ is supported near the discrete spectrum such that
$$\chi_k(k) = \begin{cases} 1 & \text{dist}(k, \mathcal{K} \cup \overline{\mathcal{K}}) < \rho/3, \\ 0 & \text{dist}(k, \mathcal{K} \cup \overline{\mathcal{K}}) > 2\rho/3. \end{cases}$$ (5.19)

The region division and the jump lines near each stationary phase point can be unified in the form of Figure 8.

Figure 8: The contours and domains near the stationary phase points $z_n$, $n = 1, 2, 3, 4$. 36
In this way, there are the same contours and domains at each stationary phase point \( z_n, n = 1, 2, 3, 4 \), as illustrated in Figure 8. Further, we have the following proposition.

**Lemma 10.** It is possible to define functions \( R_{n,j} : \overline{D}_{n,j} \to \mathbb{C} \), \( n = 1, 2, 3, 4, j = 1, 3, 4, 6 \) with boundary values satisfying:

\[
R_{n,1}(k) = \begin{cases} \frac{r(k)T(k)^2}{1+r(k)r(k)}, & k \in I_{n2}, \\ f_{n,1} = r(z_n)T_0(z_n)^{-2}(k-z_n)^{-2i\nu(z_n)[1-\chi_K(k)]}, & k \in \Sigma_{n1}, \end{cases}
\]

\[
R_{n,3}(k) = \begin{cases} \frac{r(k)T^2(k)}{1+r(k)r(k)^{-1}}, & k \in I_{n1}, \\ f_{n,3} = \frac{r(z_n)^2}{1+r(r(z_n)r(z_n))}T_0(z_n)^{-2}(k-z_n)^{-2i\nu(z_n)[1-\chi_K(k)]}, & k \in \Sigma_{n2}, \end{cases}
\]

\[
R_{n,4}(k) = \begin{cases} \frac{r(k)T^{-2}(k)}{1+r(k)r(k)}, & k \in I_{n1}, \\ f_{n,4} = \frac{r(z_n)^2}{1+r(r(z_n)r(z_n))}T_0(z_n)^{-2}(k-z_n)^{-2i\nu(z_n)[1-\chi_K(k)]}, & k \in \Sigma_{n3}, \end{cases}
\]

\[
R_{n,6}(k) = \begin{cases} \frac{r(k)T(k)^2}{1+r(k)r(k)}, & k \in I_{n2}, \\ f_{n,6} = r(z_n)T_0(z_n)^{-2}(k-z_n)^{-2i\nu(z_n)[1-\chi_K(k)]}, & k \in \Sigma_{n4}, \end{cases}
\]

\[
R_{n,2}(k) = R_{n,5}(k) = 1, \quad \text{if } k \in D_{n2} \cup D_{n5}.
\]

The functions \( R_{n,j} \) defined above have the following property:

\[
|R_{n,j}(k)| \lesssim \sin^2(\arg(k-z_n)) + (\text{Re}(k))^{-1/2},
\]

\[
|\partial R_{n,j}(k)| \lesssim |\partial \chi_K(k)| + |r'(\text{Re} k)| + |k-z_n|^{-1/2},
\]

and

\[
\partial R_{n,j}(k) = 0, \quad \text{if } k \in D_{n2} \cup D_{n5} \text{ or } \text{dist}(k,K \cup \overline{K}) < \rho/3.
\]

**Proof.** Without loss of generality, we only provide the detailed proof for \( R_{1,1} \), as other cases can be proved in a similar way. Define the function

\[
f_{1,1}(k) = r(z_1)T(k)^2T_0(z_1)^{-2}(k-z_1)^{-2i\nu(z_1)}, \quad k \in \overline{D}_{11}.
\]

Let \( k-z_1 = se^{i\phi} \), for \( k \in \overline{D}_{11} \),

\[
R_{1,1}(k) = [f_{1,1}(k) + (r(\text{Re} k) - f_{1,1}(k)) \cos(2\phi)] T(k)^{-2} (1-\chi_K(k)).
\]

Clearly, \( R_{1,1}(k) \) satisfies the boundary conditions in this lemma, as \( \cos(2\phi) \) vanishes on \( \Sigma_{11} \) and \( \chi_K(k) \) is zero on the real axis. First, consider \( |R_{1,1}(k)| \). We have

\[
|R_{1,1}(k)| \leq |2f_{1,1}(k)T(k)^{-2} (1-\chi_K(k))| \sin^2(\phi) + |T(k)^{-2} (1-\chi_K(k)) \cos(2\phi)| |r(\text{Re} k)|
\]

\[
\leq c \left( \sin^2(\phi) + (\text{Re} k)^{-1/2} \right),
\]

(5.30)
where, in the first line, we have bounded the first factor in each term of the sum on the left hand side using Proposition 9, Equation (5.19) and (5.28), by noting that the poles of \( T(k)^{-2} \) are outside the support of \( (1 - \chi_k(k)) \). In the second line, we use the fact that \( r(k) \in H^1(\mathbb{R}) \) implies that \( r \) is 1/2-Hölder continuous and \( |r(u)| \leq c(u)^{-1/2} \). As \( \partial = (\partial_x + i\partial_y)/2 = e^{i\phi} (\partial_x + i\rho^{-1}\partial_y)/2 \), we have

\[
\overline{\partial}R_{1,1}(k) = -[f_1(k) + (r(Re k) - f_{1,1}(k)) \cos 2\phi] T(k)^{-2} \overline{\partial}\chi_k(k) + \left[ \frac{1}{2} r'(Re k) \cos(2\phi) - i e^{i\phi} \frac{r(Re(k)) - f_{1,1}(k)}{|k - k_j|} \sin(2\phi) \right] T(k)^{-2} (1 - \chi_k(k)).
\]

(5.31)

According to the continuity and the decay of \( r(Re k) \) described above and the fact that both \( 1 - \chi_k(k) \) and \( \overline{\partial}\chi_k(k) \) are supported away from the discrete spectrum, the poles and the zeros of \( T(k) \) do not affect the bound. Finally, we arrive at (5.25)-(5.27), which gives the first two terms in the bound. To calculate the last term we write

\[
|r(Re k) - f_{1,1}(k)| \leq |r(Re k) - r(z_1)| + |r(z_1) - f_{1,1}(k)|,
\]

(5.32)

and use Cauchy-Schwarz inequality to bound each term as follows:

\[
|r(Re k) - r(z_1)| \leq \left| \int_{z_1}^{Re k} r'(s) ds \right| \leq \|r\|_{H^1(\mathbb{R})} |k - z_1|^{1/2},
\]

(5.33)

and

\[
|r(z_1) - f_{1,1}(k)| \leq |r(z_1)| (1 + |r(z_1)|^2) \left| T(k)^2 - T_0(z_1)^2 (k - z_1)^{2\nu(z_1)} \right| \leq c\|r\|_{H^1(\mathbb{R})} |k - z_1|^{1/2}.
\]

The last estimate uses (5.8) to bound \( T(k) \) and \( (k - z_1)^{i\nu(z_1)} \) in a neighborhood of \( k = z_1 \). (5.25)-(5.27) for \( k \in D_{11} \) follows immediately.

Now, we construct a matrix function \( R^{(2)}(k) \) for \( n = 1, 2, 3, 4 \) by

\[
R^{(2)}(k) = \begin{cases} 
\begin{pmatrix}
1 & 0 \\
-R_{n,1}(k)e^{2it\theta} & 1
\end{pmatrix}, & k \in D_{n1}, \\
\begin{pmatrix}
1 & -R_{n,3}(k)e^{-2it\theta} \\
0 & 1
\end{pmatrix}, & k \in D_{n3}, \\
\begin{pmatrix}
1 & 0 \\
R_{n,4}(k)e^{2it\theta} & 1
\end{pmatrix}, & k \in D_{n4}, \\
\begin{pmatrix}
1 & R_{n,6}(k)e^{-2it\theta} \\
0 & 1
\end{pmatrix}, & k \in D_{n6}, \\
\begin{pmatrix}
1 & 0 \\
0 & 1
\end{pmatrix}, & k \in D_{n2} \cup D_{n5},
\end{cases}
\]

(5.34)
by which we define a transformation

\[ M^{(2)}(k) = M^{(1)}(k)R^{(2)}(k), \]

(5.35)

and obtain the following mixed $\overline{\Omega}$-RH problem.

**RH Problem 5.2.** Find a function $M^{(2)}(k) = M^{(2)}(k; x, t)$ with the following properties.

(a) **Analyticity:** $M^{(2)}(k)$ is continuous in $\mathbb{C}$, sectionally continuous first partial derivatives in $\mathbb{C}\setminus(\Sigma^{(2)} \cup K \cup \overline{K})$, and meromorphic in $D_{n2} \cup D_{n5}$, $n = 1, 2, 3, 4$;

(b) **Symmetry:** $M^{(2)}(\overline{k}) = \sigma_2 M^{(2)}(k)\sigma_2$;

(c) **Jump condition:** The boundary value $M^{(2)}(k)$ at $\Sigma^{(2)}$ satisfies the jump condition

\[ M^{(2)}_+(k) = M^{(2)}_-(k)V^{(2)}(k), \quad k \in \Sigma^{(2)}, \]

(5.36)

where

\[
V^{(2)}(k) = \begin{cases}
\begin{pmatrix}
1 & 0 \\
1 & 0
\end{pmatrix}, & k \in \Sigma_{n1}, \ n = 1, 2, 3, 4, \\
\begin{pmatrix}
f_{n,1}(k)e^{2it\theta} & 1 \\
1 & 0
\end{pmatrix}, & k \in \Sigma_{n2}, \ n = 1, 2, 3, 4, \\
\begin{pmatrix}
1 & 0 \\
f_{n,3}(k)e^{-2it\theta} & 1
\end{pmatrix}, & k \in \Sigma_{n3}, \ n = 1, 2, 3, 4, \\
\begin{pmatrix}
1 & 0 \\
1 & 0
\end{pmatrix}, & k \in \Sigma_{n4}, \ n = 1, 2, 3, 4, \\
\begin{pmatrix}
1 & 0 \\
-(f_{j+1,3} - f_{j,3})e^{-2it\theta} & 1
\end{pmatrix}, & k \in \Sigma_{0j}, \ j = 1, 3, \\
\begin{pmatrix}
1 & 0 \\
f_{j+1,4}(k) - f_{j,4}(k)e^{2it\theta} & 1
\end{pmatrix}, & k \in \Sigma_{0j}, \ j = 2, 4, f_{5,4} \equiv f_{1,4}.
\end{cases}
\]

(5.37)

(d) **Asymptotic conditions:**

\[
\begin{align*}
M^{(2)}(k) &= I + \mathcal{O}(k^{-1}), \quad k \to \infty, \\
M^{(2)}(k) &= e^{-\frac{i}{2}e^{-\sigma_3}(I + kU + \mathcal{O}(k^2))}e^{\frac{i}{2}d_0\sigma_3}, \quad k \to 0;
\end{align*}
\]

(5.38)

(e) Away from $\Sigma^{(2)}$, we have

\[ \overline{\partial} M^{(2)} = M^{(2)} \overline{\partial} R^{(2)}, \]

(5.39)
which holds in $\mathbb{C}\backslash \Sigma^{(2)}$, where
\[
\mathcal{R}^{(2)} = \begin{cases} 
\begin{pmatrix} 1 & 0 \\
-1)^j\mathcal{R}_{n,j}(k)e^{2it\theta} & 1 \\
1 & 0 \\
0 & 0 \\
0 & 0 \end{pmatrix}, & k \in D_{n}, \quad n = 1, 2, 3, 4; \quad j = 1, 4, \\
\begin{pmatrix} 1 & 0 \\
-1)^j\mathcal{R}_{n,j}(k)e^{-2it\theta} & 1 \\
1 & 0 \\
0 & 0 \\
0 & 0 \end{pmatrix}, & k \in D_{n}, \quad n = 1, 2, 3, 4; \quad j = 3, 6, \\
\begin{pmatrix} 1 & 0 \\
0 & 1 \\
0 & 0 \\
0 & 0 \end{pmatrix}, & k \in D_{n}, \quad n = 1, 2, 3, 4; \quad j = 2, 5; 
\end{cases}
\]

(f) **Residue conditions:** $M^{(2)}(k)$ has simple poles at each point in $\mathcal{K} \cup \overline{\mathcal{K}}$ with:
\[
\text{Res}_{k \to k_j} M^{(2)}(k) = 0, \quad \text{Res}_{k \to \bar{k}_j} M^{(2)}(k) = 0, \quad \text{Res}_{k \to k_j} M^{(2)}(k) = 0, \quad \text{Res}_{k \to \bar{k}_j} M^{(2)}(k) = 0,
\]
where $R_-(k_j)$ and $R_+(k_j)$ is defined in (5.17).

### 5.3 Decomposition of the mixed $\mathcal{D}$-RH problem

To solve RH Problem 5.2, we decompose it into a model RH problem for $M^{rhp}(k) = M^{rhp}(k; x, t)$ with $\mathcal{D}^{(2)} = 0$ and a pure $\mathcal{D}$-Problem with $\mathcal{D}^{(2)} \neq 0$. For the first step, we establish a RH problem for the $M^{rhp}(k)$ as follows.

**RH Problem 6.1.** Find a matrix-valued function $M^{rhp}(k)$ with the following properties:

(a) **Analyticity:** $M^{rhp}(k)$ is analytical in $\mathbb{C}\backslash (\Sigma^{(2)} \cup \mathcal{K} \cup \overline{\mathcal{K}})$;

(b) **Symmetry:** $\overline{M^{rhp}(k)} = \sigma_2 M^{rhp}(k) \sigma_2$;

(c) **Jump condition:** $M^{rhp}(k)$ has continuous boundary values on $\Sigma^{(2)}$ and
\[
M^{rhp}_+(k) = M^{rhp}_-(k) V^{(2)}(k), \quad k \in \Sigma^{(2)};
\]

(d) **$\bar{\partial}$-Derivative:** $\bar{\partial}^{(2)} = 0$, for $k \in \mathbb{C}$;

(e) **Asymptotic conditions:**
\[
\begin{cases} 
M^{rhp}(k) = I + \mathcal{O}(k^{-1}), & k \to \infty, \\
M^{rhp}(k) = e^{-\frac{i}{2}e^{-\alpha_3} \left( I + kU + \mathcal{O}(k^2) \right) e^{\frac{2i}{d_3} \sigma_3}}, & k \to 0;
\end{cases}
\]

(f) **Residue conditions:** $M^{rhp}(k)$ has simple poles at each point in $\mathcal{K} \cup \overline{\mathcal{K}}$ with:
\[
\text{Res}_{k \to k_j} M^{rhp}(k) = 0, \quad \text{Res}_{k \to \bar{k}_j} M^{rhp}(k) = 0,
\]

\[
\text{Res}_{k \to k_j} M^{rhp}(k) = \lim_{k \to k_j} M^{rhp}(k) R_-(k_j), \quad k \in \Delta_{k_j}^-, \quad \text{Res}_{k \to \bar{k}_j} M^{rhp}(k) = \lim_{k \to \bar{k}_j} M^{rhp}(k) R_+(\bar{k}_j), \quad k \in \Delta_{\bar{k}_j}^+.
\]
with the definition of $R_{\pm}(k_j)$ in (5.17). The existence and the asymptotics of $M^{rhp}(k)$ will be presented in Section 8.

$M^{rhp}(k)$ can be used to construct a new matrix function

$$M^{(3)}(k) = M^{(2)}(k)M^{rhp}(k)^{-1},$$

(5.47)
in which the analytical component $M^{rhp}(k)$ disappears and it finally becomes a pure $\bar{\partial}$ problem.

**RH Problem 6.2.** Find a matrix-valued function $M^{(3)}(k) = M^{(3)}(k; x, t)$ with the following properties:

(a) **Analyticity:** $M^{(3)}(k)$ is continuous in $\mathbb{C}$, continuous first partial derivatives in $\mathbb{C} \setminus (\Sigma^{(2)} \cup K \cup \overline{K})$;

(b) **Symmetry:** $M^{(3)}(\bar{k}) = \sigma_2 M^{(3)}(k) \sigma_2$,

(c) **Asymptotic conditions:**

$$\begin{cases}
M^{(3)}(k) = I + \mathcal{O}(k^{-1}), & k \to \infty, \\
M^{(3)}(k) = e^{-\frac{\pi}{2}e^{-\sigma_3} (I + kU + \mathcal{O}(k^2)) e^{\frac{\pi}{2}d_0 \sigma_3}}, & k \to 0;
\end{cases}$$

(5.48)

(d) $\bar{\partial}$-Derivative: For $k \in \mathbb{C}$, we have

$$\bar{\partial}M^{(3)}(k) = M^{(3)}(k)W^{(3)}(k),$$

where

$$W^{(3)}(k) = M^{rhp}(k)(k)\bar{\partial}R^{(2)}M^{rhp}(k)^{-1}(k).$$

(5.49)

**Proof.** By using the properties of the solutions $M^{(2)}(k)$ and $M^{rhp}(k)$ for RH Problem 5.1 and RH Problem 6.1, the analyticity and the asymptotics are obtained immediately. As $M^{(2)}$ and $M^{rhp}$ have same jump matrix, we have

$$M^{(3)}_-(k)^{-1}M^{(3)}_+(k) = M^{(2)}_-(k)^{-1}M^{(2)}_+(k)M^{rhp}(k)^{-1}M^{rhp}(k),$$

(5.50)

$$= M^{(2)}(k)^{-1}V^{(2)}(k)^{-1}M^{(2)}_+(k) = I,$$

from which it follows that $M^{(3)}$ and its first partial derivative extend continuously to $\Sigma^{(2)}$, which immediately gives $M^{(3)}$ has no pole. For $k_j \in K$, we can verify that the coefficient matrix of the leading term in the Laurent expansion of $M^{(2)}(k)$, denoted as $N_j$, is a nilpotent matrix. Hence, we have the Laurent expansion of $k_j$ as

$$M^{(2)}(k) = a(k_j) \left[I + \frac{N_j}{k - k_j}\right] + \mathcal{O}(k - k_j),$$

(5.51)

$$M^{rhp}(k) = A(k_j) \left[I + \frac{N_j}{k - k_j}\right] + \mathcal{O}(k - k_j),$$

(5.52)
where \(a(k_j)\) and \(A(k_j)\) are the constant terms in their Laurent expansion. Then from \(M^{rhp}(k)^{-1} = \sigma_2 M^{rhp}(k)^T \sigma_2\), \(M^{(3)}(k)\) becomes

\[
M^{(3)}(k) = M^{(2)}(k)M^{rhp}(k)^{-1}
= \left\{ a(k_j) \left[ I + \frac{N_j}{k - k_j} \right] \right\} \left\{ I - \frac{N_j}{k - k_j} \right\} A(k_j)^{-1} + O(k - k_j)
= O(1),
\]

which has only removable singularities at each \(k_j\). The last property follows from the definition of \(M^{(3)}(k)\), by exploiting the fact that \(M^{rhp}(k)\) has no \(\mathcal{O}\) component.

We construct the solution \(M^{rhp}(k)\) of the RH problem 5.1 in the following form

\[
M^{rhp}(k) = \begin{cases} 
E(k)M^{(out)}(k), & k \notin \mathbb{C} \setminus U_{k_0}, \\
E(k)M^{(in)}(k), & k \in U_{k_0},
\end{cases}
\]

where \(U_{k_0} = \bigcup_{n=1}^{4} U_{z_n}\), and \(U_{z_n}\) is the neighborhood of \(z_n\):

\[
U_{z_n} = \left\{ k : |k - z_n| \leq \min \left\{ k_0/2, \rho/3 \right\} \right\}.
\]

which implies that \(M^{rhp}(k)\) has no poles in \(U_{k_0}\) as \(\text{dist}(\mathbb{K} \cup \overline{\mathbb{K}}, \Sigma) > \rho\). \(M^{rhp}\) decomposes into two parts \(M^{(out)}\) and \(M^{(in)}\). \(M^{(out)}\) solves a model RH problem obtained by ignoring the jump condition of RH Problem 5.1, which will be solved in Section 6; for \(M^{(in)}\), its solution can be approximated with parabolic cylinder functions if we let \(M^{(in)}\) match to \(M^{(2)}\) and a parabolic cylinder model in \(U_{k_0}\), which we elaborate on in Section 7. Besides, \(E(k)\) is an error function, which is a solution of a small-norm RH problem, which is discussed in details in Section 8. The jump matrix in RH Problem 6.1 admits the following estimates.

**Proposition 10.** For the jump matrix \(V^{(2)}(k)\), we have the following estimates

\[
\|V^{(2)}(k) - I\|_{L^\infty(\Sigma^{(2)} \setminus U_{k_0})} = \mathcal{O}\left( e^{-\frac{a^2}{12k_0^2}|k - z_n|^3(k^2 - |k_0|^2)^2} \right),
\]

\[
\|V^{(2)}(k) - I\|_{L^\infty(\Sigma^{(2)}_{n})} = \mathcal{O}\left( e^{-\frac{3a^2}{8k_0^2}} \right),
\]

where the contours are defined by

\[
\Sigma^{(2)}_n = \Sigma_{n1} \cup \Sigma_{n2} \cup \Sigma_{n3} \cup \Sigma_{n4}, \quad n = 1, 2, 3, 4.
\]

**Proof.** Without loss of generality, we only prove (5.57) for \(k \in \Sigma_{01}\), as other cases follow in a similar way. By using the definition of \(V^{(2)}\) and (5.25), we have

\[
\|V^{(2)}(k) - I\|_{L^\infty(\Sigma_{01})} \leq \|(R_{2,3} - R_{1,3})e^{-2i\theta}\|_{L^\infty(\Sigma_{01})} \leq c \|e^{-2i\theta}\|_{L^\infty(\Sigma_{01})}.
\]
Note that $|k| < \sqrt{2}k_0/2$. Combined with (5.3), we find that

$$|e^{-2it\theta}| = e^{-\text{Re}2it\theta} = e^{-\frac{3\alpha k^2 \text{Im} k^2}{k_0^2} + \frac{1}{k_0}} \leq e^{-\frac{3\alpha k^2 t^2}{k_0^2}} \to 0, \quad \text{as} \ t \to \infty,$$

which together with (5.59) gives (5.57). The calculation of $\Sigma (2)$, $n = 1, 2, 3, 4$ is similar. 

This proposition implies that the jump matrix $V^{(2)}(k)$ goes to $I$ on both $\Sigma^{(2)} \setminus U_{k_0}$ and $\Sigma^{(2)}_0$, so outside the $U_{k_0}$ there is only a exponentially small error of $t \to \infty$ by completely ignoring the jump condition of $M^{\text{rhp}}(k)$. According to (5.57), it is clear that $V^{(2)}(k) - I$ goes exponentially on $\Sigma^{(2)}_0$ and uniformly goes to zero as $k \to 0$. Therefore, the case of the neighborhood $k \to 0$ requires no further discussion.

6 Outer model RH problem

In this section, we build an outer model RH problem and show that its solution can approximated with a finite sum of soliton solutions. The key lies in the fact that we need the property of $M^{(\text{out})}(k)$ as $k \to \infty$, from which we obtain the solution of the following outer model problem.

6.1 Existence of soliton solutions

RH Problem 7.1. Find a matrix-valued function $M^{(\text{out})}(k)$ with the following properties:

(a) Analyticity: $M^{(\text{out})}(k)$ is analytical in $\mathbb{C}\\setminus(K \cup \overline{K})$;

(b) Symmetry: $M^{(\text{out})}(\overline{k}) = \sigma_2 M^{(\text{out})}(k) \sigma_2$;

(c) Asymptotic conditions:

$$\begin{cases}
M^{\text{out}}(k) = I + \mathcal{O}(k^{-1}), & k \to \infty, \\
M^{\text{out}}(k) = e^{-\frac{1}{2}k^2 \sigma_3} (I + kU + \mathcal{O}(k^2)) e^{\frac{1}{2}k_0 \sigma_3}, & k \to 0;
\end{cases}$$

(6.1)

(d) Residue conditions: $M^{(\text{out})}$ has simple poles at each point in $K \cup \overline{K}$ satisfying the residue conditions (5.45) and (5.46).

To show the existence and the uniqueness of the solution to RH Problem 7.1, we first consider RH Problem 3.1 under the condition of no reflection, i.e., $r(k) \equiv 0$. In this case the unknown function $M(k)$ is meromorphic. The RH Problem 3.1 reduces to the following RH problem.

RH Problem 7.2. Given the discrete data $S = \{(k_j, c_j)\}_{j=1}^{2N}$, find a matrix-valued function $m(k|S)$ with the following properties:
(a) **Analyticity**: \( m(k|S) \) is analytical in \( \mathbb{C}\setminus(K \cup \overline{K}) \),

(b) **Symmetry**: 
\[
m(K|S) = \sigma_2 m(k|S) \sigma_2,
\]

(c) **Asymptotic conditions**:
\[
\begin{cases}
  m(k|S) = I + \mathcal{O}(k^{-1}), & k \to \infty, \\
  m(k|S) = e^{-\frac{i}{2}c_1\sigma_3} \left(I + kU + \mathcal{O}(k^2)\right) e^{\frac{i}{2}d_0\sigma_3}, & k \to 0;
\end{cases}
\]

(d) **Residue conditions**: \( m(k|S) \) has simple poles at each point in \( K \cup \overline{K} \) satisfying
\[
\text{Res}_{k=k_j} m(k|S) = \lim_{k \to k_j} m(k|S) \tau_j,
\]

where \( \tau_j \) is a nilpotent matrix,
\[
\tau_j = \begin{pmatrix} 0 & 0 \\ \gamma_j & 0 \end{pmatrix}, \quad \hat{\tau}_j = \sigma_2 \tau_j \sigma_2, \quad \gamma_j = c_j e^{-2i\theta(k_j)},
\]

Moreover, the solution satisfies
\[
\|m(k|S)^{-1}\|_{L^\infty(\mathbb{C}\setminus(K \cup \overline{K}))} \lesssim 1.
\]

**Proposition 11.** The RH Problem 7.2 has a unique solution.

**Proof.** The uniqueness of the solution follows from the Liouville’s theorem. From the symmetries of \( m(k|S) \) and the residue of \( m(k|S) \) at \( k = k_j \), we know that it admits a partial fraction expansion with the following form
\[
m(k|S) = I + \sum_{j=1}^{2N} \left[ \frac{1}{k-k_j} \begin{pmatrix} \nu_j(x,t) & 0 \\ \zeta_j(x,t) & 0 \end{pmatrix} + \frac{1}{k-k_j} \begin{pmatrix} 0 & -\zeta_j(x,t) \\ 0 & \nu_j(x,t) \end{pmatrix} \right].
\]

Since \( \det(m(k|S)) = 1 \), \( \|m(k|S)\|_{L^\infty(\mathbb{C}\setminus(K \cup \overline{K}))} \) is bounded, by using a similar technique as in Appendix B and from (6.8), we simply obtain (6.7) and prove the existence of the solution for the RH Problem 7.2.

In the reflectionless case, the transmission coefficient admits the following trace formula
\[
a(k) = \prod_{j=1}^{2N} \left( \frac{k-k_j}{k-k_j} \right),
\]
whose poles can be split into two parts. Let \( \Delta \subseteq \{1, 2, \ldots, 2N\} \), we define

\[
a_{\Delta}(k) = \prod_{j \in \Delta} \left( \frac{k - k_j}{k - \bar{k}_j} \right).
\] (6.10)

With a renormalization transformation

\[
m_{\Delta}(k|D) = m(k|S) a_{\Delta}(k)^{\sigma_3},
\] (6.11)

where the scattering data are given by

\[
D = \{(k_j, c'_j)\}_{j=1}^{2N}, \quad c'_j = c_j a_{\Delta}(k)^2,
\] (6.12)

it is clear that the transformation (6.11) splits the poles of \( m_{\Delta}(k|S) \) into two columns by the choice of \( \Delta \), after which it satisfies the following modified discrete RH problem.

**RH Problem 7.3.** Given the discrete data (6.12), find a matrix-valued function \( m_{\Delta}(k|D) \) with the following properties:

(a) **Analyticity:** \( m_{\Delta}(k|D) \) is analytical in \( \mathbb{C} \setminus (K \cup \bar{K}) \);

(b) **Symmetry:** \( m_{\Delta}(k|D) = \sigma_2 m_{\Delta}(k|D) \sigma_2 \);

(c) **Asymptotic conditions:**

\[
\begin{align*}
    m_{\Delta}(k|D) &= I + \mathcal{O}(k^{-1}), & k \to \infty, \\
    m_{\Delta}(k|D) &= e^{-\frac{k}{2}e^{-\sigma_3}} (I + kU + \mathcal{O}(k^2)) e^{\frac{k}{2}\sigma_3}, & k \to 0;
\end{align*}
\] (6.13)

(d) **Residue conditions:** \( m_{\Delta}(k|D) \) has simple poles at each point in \( K \cup \bar{K} \) satisfying

\[
\begin{align*}
    \text{Res}_{k=k_j} m_{\Delta}(k|D) &= \lim_{k \to k_j} m_{\Delta}(k|D) \tau^\Delta_j, & \quad (6.14) \\
    \text{Res}_{k=\bar{k}_j} m_{\Delta}(k|D) &= \lim_{k \to \bar{k}_j} m_{\Delta}(k|D) \bar{\tau}^\Delta_j, & \quad (6.15)
\end{align*}
\]

where \( \tau^\Delta_j \) is a nilpotent matrix satisfies

\[
\tau^\Delta_j = \begin{cases} 
    \begin{pmatrix} 
        0 & 0 \\
        \gamma_j a_{\Delta}(k_j)^2 & 0 \\
        0 & \gamma_j^{-1} a_{\Delta}(k_j)^{-2} \\
    \end{pmatrix}, & j \notin \Delta, \\
    \begin{pmatrix} 
        0 & 0 \\
        \gamma_j^{-1} a_{\Delta}(k_j)^{-2} & 0 \\
        0 & 0 \\
    \end{pmatrix}, & j \in \Delta,
\end{cases}
\] (6.16)

where

\[
\tau^\Delta_j = \sigma_2 \tau^\Delta_j \sigma_2, \quad \gamma_j = c_j e^{2i\theta(k_j)}.
\] (6.17)
Since (6.11) is an explicit transformation of $m(k|S)$, by Proposition 5, we obtain the existence and the uniqueness of the solution of the RH Problem 7.3.

In the RH Problem 7.3, taking $\Delta = \Delta_{k_0}$ and replacing the scattering data $D$ with the scattering data $	ilde{D} = \{(k_j, \tilde{c}_j)\}_{j=1}^N$, we have the following corollary.

**Corollary 1.** There exists a unique solution for the RH Problem 7.1, which has the form

$$M^{\text{out}}(k) = m_{\Delta_{k_0}}(k|\tilde{D}),$$

where scattering data $\tilde{D}$ is given by (6.18).

### 6.2 Long-time behavior of soliton solutions

By choosing $\Delta$ appropriately, the asymptotic limits $t \to \infty$ with $\xi = \frac{\eta}{t} + \alpha$ and $k_0 = (\frac{\alpha \beta^2}{4})^{1/4}$ bounded are under a better asymptotic control. Then we consider the long-time behavior of soliton solutions.

By using the residue coefficients (6.17), if $N = 1$, in the reflectionless case, one soliton solution is given by

$$u_x(x,t) = 2\xi \sech[4\xi \zeta(x-vt) - \delta_0] e^{-2i \chi(x-vt) + i\kappa_0} e^{-i \{ \frac{\eta}{t} \tanh[4\xi \zeta(x-vt) - \delta_0] + |\tilde{c}| \}},$$

in which $\delta_0$ and $\kappa_0$ are real parameters and the speed of soliton is

$$v = -\alpha \left(1 - \frac{\beta^2}{4|\eta|} \right).$$

Given a pair of points $x_1 \leq x_2$ with $x_1, x_2 \in \mathbb{R}$ with velocities $v_1 \leq v_2$ with $v_1, v_2 \in \mathbb{R}^-$, we define a cone

$$C(x_1, x_2, v_1, v_2) = \{(x,t) \in \mathbb{R}^2 | x = x_0 + vt, x_0 \in [x_1, x_2], v \in [v_1, v_2]\},$$

and denote

$$\mathcal{I} = \{k : f(v_2) < |k| < f(v_1)\}, \quad f(v) \doteq \left(\frac{\alpha \beta^2}{4(v + \alpha)}\right)^{1/4},$$

$$\mathcal{K}(\mathcal{I}) = \{k_j \in \mathcal{K} : k_j \in \mathcal{I}\}, \quad N(\mathcal{I}) = |\mathcal{K}(\mathcal{I})|,$$

$$\mathcal{K}_+(\mathcal{I}) = \{k_j \in \mathcal{K} : |k_j| > f(v_1)\}, \quad \mathcal{K}_-(\mathcal{I}) = \{k_j \in \mathcal{K} : |k_j| < f(v_2)\},$$

$$c_j^{\pm}(\mathcal{I}) = c_j \prod_{\text{Re}k_n \in \mathcal{I} \setminus \mathcal{K}} \left(\frac{k_j - k_n}{k_j - \overline{k_n}}\right)^2 \exp[\pm \frac{1}{\pi i} \int_{\mathcal{I}^{\pm}} \frac{\log[1 + r(\zeta) r(\zeta)]}{\zeta - k_j} d\zeta].$$
For the \((x, t) \in C(x_1, x_2, v_1, v_2)\), a direct calculation leads to
\[
k \in \mathcal{I} = \{k : f(v_2) \leq |k| \leq f(v_1)\},
\]
which implies that a proportion of the discrete spectrums would fall in the circular region
\[
\mathcal{K}(\mathcal{I}) = \{k_j \in \mathcal{K} \mid k_j \in \mathcal{I}\}.
\]

Define
\[
\mu = \min_{k_j \in \mathcal{K} \setminus \mathcal{K}(\mathcal{I})} \{\text{Re } k_j \text{ Im } k_j \text{ dist } (v_{k_j} - v)\},
\]
where
\[
v_{k_j} = -\alpha \left(1 - \frac{\beta^2}{4|k_j|^4}\right),
\]
is the velocity of one soliton corresponding to the discrete spectrum \(k_j\). The value \(v_{k_j} - v\) represents the difference between the velocity of one soliton corresponding to \(k_j\).

**Proposition 12.** The choice of normalization \(\Delta = \Delta_{k_0}^{\mp}\) in RH Problem 7.3 ensures that as \(t \to \infty\) with \((x, t) \in C(x_1, x_2, v_1, v_2)\) that
\[
\left\| \tau_{x_0}^{\Delta} \right\| = \begin{cases} \mathcal{O}(1), & k_j \in \mathcal{K}(\mathcal{I}), \\ \mathcal{O}(e^{-4\mu t}), & k_j \in \mathcal{K} \setminus \mathcal{K}(\mathcal{I}), \end{cases} \quad t \to \infty.
\]
Proof. We take $\Delta = \Delta_{k_0}$ in the RH Problem 7.3. Then, for $k_j \in \mathcal{K}_-(I)$ and $(x, t) \in \mathcal{C}(x_1, x_2, v_1, v_2)$, by using the residue condition (6.14),

$$|\gamma_j(x_0 + vt, k_j)| \leq c \left|e^{-2it\theta(k_j)}\right|,$$

(6.27)

for the exponential part on the right, we have

$$-2it\theta(k_j) = -2ix_0k_j^2 - 2it(vk_j^2 + \alpha k_j^2 - \alpha\beta + \frac{\alpha\beta^2}{4k_j^2}).$$

(6.28)

To get the modulus of $e^{-2it\theta(k_j)}$, we calculate the real parts of the right side

$$\text{Re} \left( -2ix_0k_j^2 - 2it(vk_j^2 + \alpha k_j^2 - \alpha\beta + \frac{\alpha\beta^2}{4k_j^2}) \right) = 2x_0 \text{Re} k_j \text{Im} k_j - 4t \text{Re} k_j \text{Im} k_j (v_j - v),$$

(6.29)

where we set

$$v_{k_j} = -\alpha \left(1 - \frac{\beta^2}{4|k_j|^2}\right).$$

(6.30)

Therefore,

$$|e^{-2it\theta(k_j)}| = e^{2x_0\text{Re} k_j \text{Im} k_j} e^{-4t\text{Re} k_j \text{Im} k_j (v_j - v)} \leq ce^{-4\mu t}.$$  

(6.31)

By using the above estimates, we obtain the following result.

Lemma 11. Fix the reflectionless data $S = \{(k_j, c_j)\}_{j=1}^N, D^\pm(I) = \{(k_j, c_j^\pm(I)) | k_j \in \mathcal{K}(I)\}$. Then as $t \to \infty$ with $(x, t) \in \mathcal{C}(x_1, x_2, v_1, v_2)$, we have

$$m^\Delta (k|D) = (I + \mathcal{O}(e^{-4\mu t}))m^\Delta_{k_0}(k|D^\pm(I)),$$

(6.32)

with

$$c_j^\pm(I) = c_j \prod_{\text{Re } k_n \in I \setminus I} \left(\frac{k_j - k_n}{k_j - k_n}\right)^2.$$

Proof. Denote small disks centered at each $k_j \in \mathcal{K}\setminus\mathcal{K}(I)$ with a radius smaller than $\mu(I)$ as $S_j$ respectively, with $\partial S_j$ representing the boundary of $S_j$. Then we introduce a new transformation which can remove the poles $k_j \in \mathcal{K}\setminus\mathcal{K}(I)$ and these residues change to near-identity jumps.

$$m^{\Delta_{k_0}}(k|D) = \begin{cases} m^{\Delta_{k_0}}(k|D)(I - \frac{\tau_{k_j}}{k_j - k_j}), & k \in S_j, \\ m^{\Delta_{k_0}}(k|D)(I - \frac{2\pi i\tau_{k_j}}{k_j - k_j}), & k \in \overline{S_j}, \\ m^{\Delta_{k_0}}(k|D), & \text{elsewhere}. \end{cases}$$

(6.33)
Comparing with \( m^{\Delta k_0}(k|D) \) the new matrix function \( \tilde{m}^{\Delta \tilde{k}_0}(k|D) \) has a new jump in each \( \partial S_j \) which we denote by \( \tilde{V}(k) \)

\[
\tilde{m}^{\Delta \tilde{k}_0}_+(k|D) = \tilde{m}^{\Delta \tilde{k}_0}(k|D)\tilde{V}(k), \quad k \in \tilde{\Sigma},
\]

(6.34)

where

\[
\tilde{\Sigma} = \cup_{k_j \in K \setminus K(I)} (\partial S_j \cup \partial \overline{S}_j).
\]

Then using (6.33), we have

\[
\|\tilde{V}(k) - I\|_{L^\infty(\tilde{\Sigma})} = O(e^{-4\mu t}).
\]

(6.35)

Since \( \tilde{m}^{\Delta \tilde{k}_0}(k|D) \) has the same poles and residue conditions with \( m^{\Delta k_0}(k|D) \), then

\[
m_0(k) = \tilde{m}^{\Delta \tilde{k}_0}(k|D)m^{\Delta k_0}(I)|D^\pm(I))^{-1},
\]

(6.36)

has no poles, but it has a jump matrix for \( k \in \tilde{\Sigma} \)

\[
m_0^+(k) = m_0^-(k)V_{m_0}(k).
\]

(6.37)

Combine (6.34), (6.36), (6.37) and under the fact that the solution of RH Problem 7.2 has no jump, the jump matrix \( V_{m_0}(k) \) is given by

\[
V_{m_0}(k) = m(k|D^\pm(I))\tilde{V}(k)m(k|D^\pm(I))^{-1},
\]

(6.38)

which, by using (6.35), also admits the same decaying estimate

\[
\|V_{m_0}(k) - I\|_{L^\infty(\tilde{\Sigma})} = \|\tilde{V}(k) - I\|_{L^\infty(\tilde{\Sigma})} = O(e^{-4\mu t}), \quad t \to \infty.
\]

(6.39)

Using the reconstruction formula to \( m^{\Delta \tilde{k}_0}(k|D) \), we immediately obtain the following result.

**Corollary 2.** Let \( m_{sol}(x,t|D) \) and \( m_{sol}(x,t|D(I)) \) denote the N-soliton solution of (1.1) corresponding to discrete scattering data \( S \) and \( D(I) \) respectively, with \( I, C(x_1, x_2, v_1, v_2) \), \( D(I) \) given above. As \( t \to \infty \) with \( (x, t) \in C(x_1, x_2, v_1, v_2) \), we have

\[
2i \lim_{k \to \infty} k(m(k|D))^{12} = m_{sol}(x,t|D) = m_{sol}(x,t|D(I)) + O(e^{-4\mu t}).
\]

(6.40)

From the outer model we arrive at the following corollary.
Corollary 3. The RH Problem 7.1 has a unique solution $M^{\text{out}}$ with

$$
M^{\text{out}}(k) = m^\Delta_{k_0}(|D^{\text{out}}|) \prod_{\Re k_j \in I_+ \setminus I} (\frac{k_j - k}{k - k_j})^{-\sigma_3} \delta^{-\sigma_3} + \mathcal{O}(e^{-4\mu t}),
$$

(6.41)

where $D^{\text{out}} = \{k_j, c_j(z_n)\}_{j=1}^{2N}$, $n = 1, 2, 3, 4$,

$$
c_j(z_n) = c_j \exp \left[ -\frac{1}{\pi i} \int_{I_+} \frac{\log \left[ 1 + r(\zeta) \tilde{r}(\zeta) \right]}{\zeta - z_n} d\zeta \right].
$$

(6.42)

Then substituting (6.41) into (6.7) we immediately have

$$
\|M^{\text{out}}(k)^{-1}\|_{L^\infty(\mathbb{C} \setminus \Sigma)} \lesssim 1,
$$

(6.43)

Moreover, we have the reconstruction formula

$$
M^{\text{out}}(k) = m(x, t|D^{\text{out}}(I)) = m(x, t|D^{\text{out}}(I)) + \mathcal{O}(e^{-4\mu t}),
$$

(6.44)

and

$$
m_{\text{sol}}(x, t|D^{\text{out}}) = m_{\text{sol}}(x, t|D(I)) + \mathcal{O}(e^{-4\mu t}), \quad t \to \infty.
$$

(6.45)

7 A local solvable RH model near phase points

From Proposition 4, we find that $V^{(2)}(k) - I$ in the neighborhood $U_{k_0}$ of $z_n$, $n = 1, 2, 3, 4$ does not have a uniformly small jump for $t \to \infty$. Therefore, we establish a local model $M^{\text{in}}(k)$ which exactly matches the jumps of $M^{\text{rhp}}(k)$ on $\Sigma^{(2)} \cap U_{k_0}$ for the function $E(k)$. Then it has a uniform estimate on the decay of the jump.

RH Problem 8.1. Find a matrix-valued function $M^f(k)$ such that

(a) Analyticity: $M^f(k)$ is analytical in $\mathbb{C} \setminus \Sigma^f$, $\Sigma^f = \bigcup_{n,j=1}^4 \Sigma_{nj}$;

(b) Asymptotic conditions:

$$
\begin{align*}
M^f(k) &= I + \mathcal{O}(k^{-1}), \quad k \to \infty, \\
M^f(k) &= e^{-\frac{2}{\sqrt{-1}} \sigma_3 (I + kU + \mathcal{O}(k^2))} e^{\frac{2}{\sqrt{-1}} d \sigma_3}, \quad k \to 0;
\end{align*}
$$

(7.1)

(c) Jump condition: $M^f(k)$ has continuous boundary values $M^f_{\pm}(k)$ on $\Sigma^f$ and

$$
M^f_{\pm}(k) = M^f_{\pm}(k) V^f(k), \quad k \in \Sigma^f,
$$

(7.2)
where the jump matrix \( V^J(k) \) is given by

\[
V^J(k) = \begin{cases} 
    \begin{pmatrix} 1 & 0 \\
    r(z_n)\delta^2(z_n)(k-z_n)^{-2i\nu(z_n)}e^{2it\theta(k)} & 1 \\
    0 & 1 
    \end{pmatrix}, & k \in \Sigma_{n1}, \ n = 1, 2, 3, 4, \\
    \begin{pmatrix} 1 & 0 \\
    r(z_n)\delta(z_n)^2(k-z_n)^{-2i\nu(z_n)}e^{-2it\theta(k)} & 1 \\
    0 & 1 
    \end{pmatrix}, & k \in \Sigma_{n2}, \ n = 1, 2, 3, 4, \\
    \begin{pmatrix} 1 & 0 \\
    r(z_n)\delta(z_n)^2(k-z_n)^{-2i\nu(z_n)}e^{2it\theta(k)} & 1 \\
    0 & 1 
    \end{pmatrix}, & k \in \Sigma_{n3}, \ n = 1, 2, 3, 4, \\
    \begin{pmatrix} 1 & 0 \\
    r(z_n)\delta(z_n)^2(k-z_n)^{-2i\nu(z_n)}e^{-2it\theta(k)} & 1 \\
    0 & 1 
    \end{pmatrix}, & k \in \Sigma_{n4}, \ n = 1, 2, 3, 4. 
\end{cases}
\]

(7.3)

For the soliton-free case when there are no discrete spectrum, the formula (5.10) reduces to \( T_0(z_n) = \delta(z_n) \). We take \( z_3 \) as an example and other three stationary-phase points can be handled in the same way. Expanding \( \theta(k) \), we obtain

\[
\theta(k) = \frac{\alpha \beta^2}{4} \left( \frac{k^2}{k^2_0} + \frac{1}{k^2} \right) - \alpha \beta \\
= \frac{\alpha \beta^2}{2k^2_0} - \alpha \beta + \frac{\alpha \beta^2}{k^2} (k-z_3)^2 + \left( \frac{\alpha \beta^2}{4k^2_0} - \frac{3\alpha \beta^2}{4k^2} \right) (k-z_3)^3. 
\]

(7.4)

We define the following scaling transformation

\[
N : f(k) \rightarrow (Nf)(k) = f\left( \frac{k^2}{2\beta \sqrt{\alpha t}} \zeta + z_3 \right), 
\]

(7.5)

which acts on \( \delta(k)e^{-it\theta(k)} \) and gives

\[
(N\delta e^{-it\theta})(k) = \delta^0(\zeta)\delta^1(\zeta), 
\]

(7.6)

where

\[
\delta^0(\zeta) = \frac{e^{it\nu(z_1)-2i\nu(z_2)}}{(\sqrt{\alpha t}\beta)^{\nu(z_1)}}2^{-i\nu(z_2)}e^{i(\alpha \beta - \frac{\alpha \beta^2}{2i\nu})t}e^{\chi_3(z_3)\chi_3'(z_3)}, 
\]

(7.7)

and

\[
\delta^1(\zeta) = \zeta^{i\nu}e^{-\frac{i^2}{4}e^{-\frac{k^2}{2\nu(z_2)}}\left( \frac{k^2}{2\nu(z_2)} + \frac{2i\nu(z_2)}{z_3} \right)2^{-i\nu(z_2)-i\nu(z_3)}\tilde{\chi}^3(\zeta + z_3)\tilde{\chi}^3'(\zeta + z_3)} \\
\times \left( \frac{k^2}{2\nu(z_2)} - \zeta + z_3 \right) \left( \frac{k^2}{2\nu(z_2)} - \zeta + z_3 + z_4 \right)^{-i\nu} \\
\times e^{\chi_3(\zeta + z_3)\chi_3'(\zeta + z_3)}e^{\tilde{\chi}^3(\zeta + z_3)\tilde{\chi}^3'(\zeta + z_3)}, 
\]

(7.8)
for which
\[
\chi_n'(k) = e^{-\frac{k^2}{2\pi} f_0^2 n |k-k'| d\ln(1-r(k')/r(k))}, \quad n = 1, 2, 3, 4. \tag{7.9}
\]
The result here is based on [14]. Instead of using the Taylor expansion of \(\theta(k)\), we explicitly write the coefficients of the power terms in the form of splitting. The benefits of this method will be made clear in our subsequent calculations.

**Proposition 13.** As \(t \to \infty\), for \(\zeta \in \{\zeta = u k_0 e^{\pm i\pi/4}, -\epsilon < u < \epsilon\}\), by observing \(\delta^1(\zeta)\), we have the following conclusion
\[
\delta^1(\zeta) \sim \zeta^{i\nu} e^{-i\frac{\zeta^2}{4}}. \tag{7.10}
\]
by using the result of
\[
|e^{-i\frac{k_0^3 \zeta^2}{32\sqrt{\alpha t\beta}}(\frac{1}{\zeta} - \frac{3}{k_0})}| \to 1, \quad \text{as } t \to \infty. \tag{7.11}
\]

**Proof.** For \(\zeta = u k_0 e^{\pm i\pi/4}\), the index part becomes
\[
-i \frac{k_0^3 \zeta^2}{32\sqrt{\alpha t\beta}}(1 - \frac{3}{k_0}) = -i \sqrt{2} k_0^4 u + \frac{k_0^4}{64\sqrt{\alpha t\beta}} (\frac{\sqrt{2}}{2} u - 3u^2), \tag{7.12}
\]
so we have
\[
|e^{-i\frac{k_0^3 \zeta^2}{32\sqrt{\alpha t\beta}}(\frac{1}{\zeta} - \frac{3}{k_0})}| = e^{Re\left\{-i\frac{k_0^3 \zeta^2}{32\sqrt{\alpha t\beta}}\left(\frac{1}{\zeta} - \frac{3}{k_0}\right)\right\}} = e^{\frac{k_0^4}{32\sqrt{\alpha t\beta}}(\frac{\sqrt{2}}{2} u - 3u^2)} \tag{7.13}
\]
\[
\leq e^{\frac{k_0^4}{32\sqrt{\alpha t\beta}}|u|^2} \leq e^{\frac{k_0^4}{32\sqrt{\alpha t\beta}}(\frac{\sqrt{2}}{2} |u| + 3|u|^2)} \to 1, \quad \text{as } t \to \infty.
\]
by which the effects of the third power can be ignored.

To solve this problem, we need to begin from the PC-model of four stationary-phase points and their jump lines, as illustrated in Figure 10.

\[\text{Figure 10: The jump contour for the local RH problem near the phase points } z_n, n = 1, 2, 3, 4.\]
We set
\[ r_0 = r(z_3) \delta(z_3)^{-2} e^{i\nu(z_3)[\ln k_0^4 - \ln 4\alpha \beta^2 t]} e^{2it\left(\frac{z_3^2}{2k^2} - \alpha \beta^2\right)}. \] (7.14)

Moreover, with the notation in Proposition 3, we have
\[ M_{p_1}^{p_1}(\zeta) = I + \frac{M_{p_1}^{p_1}(z_3)}{i\zeta} + O(\zeta^{-2}), \] (7.15)
where
\[ M_{p_1}^{p_1}(z_3) = \begin{pmatrix} 0 & \beta_{12}(r_{z_3}) \\ \beta_{21}(r_{z_3}) & 0 \end{pmatrix}. \] (7.16)
with
\[ \beta_{12}(r_{z_3}) = \frac{\sqrt{2} \pi e^{i\pi/4} e^{-\pi\nu(z_3)/2}}{r_{z_3} \Gamma(-i\nu(z_3))}. \] (7.17)
\[ \beta_{21}(r_{z_3}) = \frac{-\sqrt{2} \pi e^{-i\pi/4} e^{-\pi\nu(z_3)/2}}{r_{z_3} \Gamma(i\nu(z_3))}. \] (7.18)

For another three points, the calculation is proceeded in the same way.
\[ M_{p_n}^{p_n}(\zeta) = I + \frac{M_{p_n}^{p_n}(z_n)}{i\zeta} + O(\zeta^{-2}), \quad \zeta \to \infty, \quad n = 1, 2, 4. \] (7.19)

We note that in the model RH problem, the origin is the reference point from which the rays emanate. In the following sections, we fix the notation \( \zeta \) for convenience. Since \( M^{fl} \) satisfies the asymptotic property
\[ M^{fl} = I + \frac{1}{i\zeta} \sum_{n=1}^{4} M_{p_n}^{p_n}(z_n) + O(\zeta^{-2}), \quad \zeta \to \infty, \] (7.20)
Substituting (7.5) into (7.20), it becomes
\[ M^{fl} = I + \frac{k_0^2}{2\beta \sqrt{\alpha t}} \sum_{n=1}^{4} \frac{M_{p_n}^{p_n}(z_n)}{k - z_n} + O(\zeta^{-2}), \quad \zeta \to \infty. \] (7.21)

In the local circular domain of \( z_n \)
\[ \left| \frac{1}{k - z_n} \right| \leq c, \] (7.22)
where \( c \) is independent of \( k \). The other three points can be controlled in the same way. We can also reach a consistent conclusion that
\[ |M^{fl} - I| \lesssim O(t^{-1/2}). \] (7.23)

Besides, it is shown that
\[ \|M^{fl}(\zeta)\|_{\infty} \lesssim 1, \] (7.24)
We use $M^{fl}(\zeta)$ to define a local model

$$M^{(in)}(k) = M^{(out)}(k)M^{fl}(\zeta), \quad (7.25)$$

which is a bounded function in $U_{k_0}$ and has the same jump matrix as $M^{rhp}(k)$.

8 Small-norm RH problem for error function

From the definition (5.54) and (7.25), we find a RH problem for the matrix function $E(k)$. In this section, we consider the error matrix-function $E(k)$.

**RH Problem 9.1.** Find a matrix-valued function $E(k)$ with following properties:

(a) **Analyticity:** $E(k)$ is analytical in $\mathbb{C}\setminus \Sigma^{(E)}$ and

$$\Sigma^{(E)} = \bigcup_{n=1}^{4} \partial U_{z_n} \cup (\Sigma^{(2)}\setminus U_{k_0}),$$

where we orient $\partial U_{z_n}$ clockwise;

(b) **Symmetry:**

$$\overline{E(k)} = \sigma_2 E(k) \sigma_2^{-1}; \quad (8.1)$$

(c) **Asymptotic conditions:**

$$\begin{cases} 
E(k) = I + \mathcal{O}(k^{-1}), & k \to \infty, \\
E(k) = e^{-\frac{i}{2}c-\sigma_3} (I + kU + \mathcal{O}(k^2)) e^{\frac{i}{2}d_0\sigma_3}, & k \to 0; \quad (8.2)
\end{cases}$$

(d) **Jump condition:** $E(k)$ has continuous boundary values $E_{\pm}$ on $\Sigma^{(E)}$ satisfying

$$E_+(k) = E_-(k)V^{(E)}, \quad (8.3)$$

where the jump matrix $V^{(E)}$ is given by

$$V^{(E)}(k) = \begin{cases} 
M^{(out)}(k)V^{(2)}(k)M^{(out)}(k)^{-1}, & k \in \Sigma^{(2)}\setminus U_{k_0}, \\
M^{(out)}(k)M^{fl}(k)M^{(out)}(k)^{-1}, & k \in \bigcup_{n=1}^{4} \partial U_{z_n}, \quad (8.4)
\end{cases}$$

which is shown in Figure 11.
Figure 11: The jump contour $\Sigma^{(E)}$ for the $E(k)$.

We will show that for large times, the error function $E(k)$ solves the following small-norm RH problem.

By using (6.43) and Proposition 2, we have the following estimates

$$\left| V^{(E)}(k) - I \right| \lesssim \begin{cases} O\left( e^{-\frac{\pi^2}{32\alpha^2}|k-z_n|^3} \right), & k \in \Sigma^{(2)} \setminus U_{k_0}, \\ O\left( e^{-\frac{\pi^2}{32\alpha^2}t} \right), & k \in \Sigma_0^{(2)}. \end{cases} \quad (8.5)$$

By using (6.43) with (7.23), we show that

**Proposition 14.** For $k \in \bigcup_{n=1}^4 \partial U_{z_n}$, we find that

$$\left| V^{(E)}(k) - I \right| = \left| M^{(\text{out})}(k)^{-1}(M^{(I)}(k) - I)M^{(\text{out})}(k) \right| = O(t^{-1/2}). \quad (8.6)$$

By using the Beal-Coffman theory, the solution of RH Problem 9.1 can be expressed as

$$E(k) = I + \frac{1}{2\pi i} \int_{\Sigma^{(E)}} \rho(s)\frac{V^{(E)}(s) - I}{s - k} ds, \quad (8.7)$$
where \( \rho(s) \in L^2(\Sigma^{(E)}) \) is the solution of the following equation

\[
(1 - C_{E}) \rho(s) = I. \tag{8.8}
\]

The singular integral operator \( C_{E} \) is defined by

\[
C_{E}f = C_{-}(f(V^{(E)} - I)), \tag{8.9}
\]

and \( C_{-} \) is the Cauchy projection operator defined as

\[
C_{-}f(k) = \lim_{k' \to k \in \Sigma^{(E)}} \frac{1}{2\pi i} \int_{\Sigma^{(E)}} \frac{f(s)}{s - k'} ds.
\]

By using estimates (8.5), (8.6) and (8.9), we show that

\[
\|C_{E}\|_{L^2(\Sigma^{(E)}) \to L^2(\Sigma^{(E)})} \lesssim t^{-1/2},
\]

\[
\|\rho(k) - I\|_{L^2(\Sigma^{(E)})} \lesssim \frac{\|C_{E}\|}{1 - \|C_{E}\|} \lesssim t^{-1/2}, \tag{8.10}
\]

which implies that the operator equation (8.8) has a unique solution for a sufficiently large \( t \). Then the existence and the uniqueness of the RH Problem 9.1 is shown by the theorem of a small-norm RH problem.

To reconstruct the solution \( u_x(x,t) \) of the FL equation (1.2), we need the asymptotic behavior of \( E(k) \) as \( k \to \infty \).

**Proposition 15.** As \( k \to \infty \), we have the asymptotic expansion

\[
E(k) = I + \frac{E_1}{k} + \mathcal{O}\left(\frac{1}{k^2}\right), \tag{8.11}
\]

where

\[
E_1 = \frac{k_0^2}{2i\beta\sqrt{\alpha} t} \sum_{n=1}^{4} (-1)^{n+1} M^{(out)}(z_n) M^{pc} M^{pc}(z_n) M^{(out)}(z_n)^{-1} + \mathcal{O}(t^{-1}). \tag{8.12}
\]

**Proof.** Combining (8.5), (8.6) and (8.10), we have

\[
E_1 = -\frac{1}{2\pi i} \int_{\Sigma^{(E)}} (V^{(E)}(s) - I) ds + \mathcal{O}(t^{-1})
\]

\[
= \frac{k_0^2}{2i\beta\sqrt{\alpha} t} \sum_{n=1}^{4} (-1)^{n+1} M^{(out)}(z_n) M^{pc} M^{pc}(z_n) M^{(out)}(z_n)^{-1} + \mathcal{O}(t^{-1}). \tag{8.13}
\]

Consider

\[
2i(E_1)_{12} = t^{-1/2} f(x,t) + \mathcal{O}(t^{-1}), \tag{8.14}
\]
where
\[
  f(x,t) = \frac{\lambda^2}{\beta \sqrt{\alpha}} \sum_{n=1}^{4} (-1)^{n+1} \left( \beta_{12}(r_{\bar{z}_n}) M_{11}^{(out)}(\bar{z}_n)^2 + \beta_{21}(r_{\bar{z}_n}) M_{12}^{(out)}(\bar{z}_n)^2 \right). \tag{8.15}
\]

9 Asymptotic analysis on the pure $\overline{\partial}$-problem

Under the discussion of $\mathcal{M}rhp(k)$ in Section 5.3 and 6, the part with $\overline{\partial}R^{(2)}(k) = 0$ can be eliminated based on (5.47), after which we consider the properties and the long-time asymptotics behavior of $M^{(3)}(k)$. The solution of RH Problem 6.2 is equivalent to the integral equation

\[
  M^{(3)}(k) = I - \frac{1}{\pi} \int_{\mathbb{C}} \frac{M^{(3)}(s) W^{(3)}(s)}{k - s} dm(s), \tag{9.1}
\]

where $dm(s)$ is the Lebesgue measure on the $\mathbb{C}$. If we denote $C_k$ is the left Cauchy-Green integral operator,

\[
  fC_k(k) = -\frac{1}{\pi} \int_{\mathbb{C}} \frac{f(s) W^{(3)}(s)}{k - s} dm(s), \tag{9.2}
\]

then above equation can be rewritten as

\[
  M^{(3)}(k) = I \cdot (I - C_k)^{-1}. \tag{9.3}
\]

To prove the existence of operator $(I - C_k)^{-1}$, we need the following lemma.

**Lemma 12.** The norm of the integral operator $C_k$ decays to zero as $t \to \infty$:

\[
  \|C_k\|_{L^\infty \to L^\infty} \leq ct^{-1/4}, \tag{9.4}
\]

which implies that $(I - C_k)^{-1}$ exists.

**Proof.** For any $f \in L^\infty$

\[
  \|fC_k\|_{L^\infty} \leq \|f\|_{L^\infty} \frac{1}{\pi} \int_{\mathbb{C}} \frac{|W^{(3)}(s)|}{|k - s|} dm(s)
  \leq \|f\|_{L^\infty} \frac{1}{\pi} \int_{\mathbb{C}} \frac{|\overline{\partial}R^{(2)}(s)|}{|k - s|} dm(s), \tag{9.5}
\]

on account of

\[
  |W^{(3)}(s)| \leq \|M^{rhp}\|_{L^\infty} \|\overline{\partial}R^{(2)}(s)\| \|M^{rhp}\|^{-1}_{L^\infty} \lesssim |\overline{\partial}R^{(2)}(s)|. \tag{9.6}
\]
After simplifying, we only need to estimate
\[ \frac{1}{\pi} \int_{C} \frac{|\partial R^{(2)}(s)|}{|k - s|} dm(s). \] (9.7)

As \( \partial R^{(2)}(s) \) is a piece-wise function, we detail the case in the region \( D_{11} \), and the other regions can be handled in a similar way. From (5.26), we have
\[ \int_{D_{11}} \frac{|\partial R^{(2)}(s)|}{|k - s|} dm(s) \leq F_1 + F_2 + F_3, \] (9.8)
where
\[ F_1 = \int_{0}^{+\infty} \int_{z_1 + v}^{+\infty} |\bar{\mathcal{X}}_k'(u)| e^{\alpha \beta^2 uv(t) \left( \frac{1}{(u^2 + v^2)^{1/2}} - \frac{1}{k_0^2} \right)} \frac{dudv}{\sqrt{(u - x)^2 + (v - y)^2}}, \] (9.9)
\[ F_2 = \int_{0}^{+\infty} \int_{z_1 + v}^{+\infty} |\bar{\mathcal{X}}_k'(u)| e^{\alpha \beta^2 uv(t) \left( \frac{1}{(u^2 + v^2)^{1/2}} - \frac{1}{k_0^2} \right)} \frac{dudv}{\sqrt{(u - x)^2 + (v - y)^2}}, \] (9.10)
\[ F_3 = \int_{0}^{+\infty} \int_{z_1 + v}^{+\infty} (u - z_1)^2 + v^2 \frac{1}{(u^2 + v^2)^{1/2}} - \frac{1}{k_0^2} \frac{dudv}{\sqrt{(u - x)^2 + (v - y)^2}}. \] (9.11)

We denote \( s = u + iv, k = x + iy \).

In the following calculation, we will use the inequality
\[ ||s - k||_{L^2(z_1, +\infty)}^{-2} = \int_{z_1}^{+\infty} \frac{1}{|u - v|} \left( \frac{\|u - x\|^2 + 1}{|v - y|} \right)^{-1} d(v - y) \leq \frac{\pi}{|v - y|}. \] (9.12)

Without loss of generality, we suppose \( y > 0 \), because, if \( y < 0 \), we can directly remove the absolute value sign and use the same way for estimation.

For \( F_1 \), noting that \( \alpha \beta^2 uv(t) \left( \frac{1}{(u^2 + v^2)^{1/2}} - \frac{1}{k_0^2} \right) \) is a monotonic decreasing function of \( u \), we have
\[ F_1 \leq \int_{0}^{+\infty} \|s - k\|_{L^2(v + z_1, +\infty)}^{-1} \|\bar{\mathcal{X}}_k(s)\|_{L^2(v + z_1, +\infty)} e^{\alpha \beta^2 v(t) (v + z_1) t} \left( \frac{1}{(u^2 + v^2)^{1/2}} - \frac{1}{k_0^2} \right) dv \]
\[ \leq c \int_{0}^{+\infty} |v - y|^{-1/2} e^{\alpha \beta^2 v(t) (v + z_1) t} \left( \frac{1}{(u^2 + v^2)^{1/2}} - \frac{1}{k_0^2} \right) dv \]
\[ \leq c \int_{0}^{+\infty} |v - y|^{-1/2} e^{-\frac{\alpha \beta^2 v(t)}{k_0^2}} dv \leq ct^{-1/4}. \]

The \( F_2 \) has the same estimate with \( F_1 \). For \( F_3 \), we choose \( p > 2 \) and \( q \) Hölder conjugate to
For the first term, using the inequality $e^{-z} \leq cz^{-1/4}$ for all $z > 0$ leads to

$$\int_0^y v^{1/p-1/2} (y - v)^{1/q - 1} e^{\alpha \beta^2 v (v + z)} t \left( - \frac{1}{\zeta_0} \right) dv \leq ct^{-1/4} \int_0^y v^{1/p-1/2} (y - v)^{1/q - 1} dv \leq c t^{-1/4}. \quad (9.16)$$

Similarly, we estimate the second term in the same way of estimating $F_1$. Let $w = v - y$. Then

$$\int_y^{+\infty} v^{1/p-1/2} (v - y)^{1/q - 1} e^{\alpha \beta^2 v (v + z)} t \left( - \frac{1}{\zeta_0} \right) dv \leq \int_0^{+\infty} w^{1/q - 1} (w + y)^{1/p-1/2} e^{-\frac{\alpha \beta^2}{\zeta_0} t (w+y)^2} dw \leq ct^{-1/4} \int_0^{+\infty} w^{-1/2} e^{-\frac{\alpha \beta^2 t w^2}{\zeta_0}} dw \leq c t^{-1/4}. \quad (9.17)$$
Finally, we have
\[ F_3 \leq ct^{-1/4}. \] (9.18)

Based on the previous formula we arrive at the primary result.

Consider the asymptotic expansion of \( M^{(3)}(k) \) at \( k = \infty \)
\[ M^{(3)}(k) = I + \frac{M_1^{(3)}(x,t)}{k} + O(k^{-2}), \quad k \to \infty, \] (9.19)
where
\[ M_1^{(3)}(x,t) = \frac{1}{\pi} \int_C M^{(3)}(s) W^{(3)}(s) dm(s), \] (9.20)

To reconstruct the solution \( u_x(x,t) \) of the FL equation (1.2), we need the asymptotic behavior of \( M_1^{(3)}(x,t) \).

**Lemma 13.** For a large \( t \), we have
\[ |M_1^{(3)}(x,t)| \leq ct^{-3/4}. \] (9.21)

**Proof.** By using (9.19) and (9.20), also noting the boundedness of \( M^{(3)}(k) \) and \( M^{rhp}(k) \), we obtain that
\[
\| M_1^{(3)}(x,t) \| \leq \frac{1}{\pi} \int_{D_{11}} |M^{(3)} M^{rhp} \partial R^{(2)} M^{rhp-1}| dm(s) \\
\leq c \int_0^{+\infty} \int_{z_1+v}^{+\infty} |\partial R_1(s)| e^{\alpha^2 uvt \left( \frac{1}{(u^2 + v^2)^2} - \frac{k}{\pi^2} \right)} dudv \\
\leq c(I_1 + I_2 + I_3), \] (9.22)
with
\[
I_1 = \int_0^{+\infty} \int_{z_1+v}^{+\infty} |\partial X_K(s)| e^{\alpha^2 uvt \left( \frac{1}{(u^2 + v^2)^2} - \frac{k}{\pi^2} \right)} dudv, \] (9.23)
\[
I_2 = \int_0^{+\infty} \int_{z_1+v}^{+\infty} |\nu'(u)| e^{\alpha^2 uvt \left( \frac{1}{(u^2 + v^2)^2} - \frac{k}{\pi^2} \right)} dudv, \] (9.24)
\[
I_3 = \int_0^{+\infty} \int_{z_1+v}^{+\infty} (u - z_1)^2 v^2 e^{\alpha^2 uvt \left( \frac{1}{(u^2 + v^2)^2} - \frac{k}{\pi^2} \right)} dudv. \] (9.25)
We bound $I_1$ by applying the Cauchy-Schwarz inequality:

$$I_1 = \int_0^{+\infty} \int_{z_1+v}^{+\infty} |\partial X_X(s)| e^{\alpha \beta^2 u v t \left( \frac{1}{u^2+v^2} - \frac{1}{v^2} \right)} du dv$$

$$\leq \int_0^{+\infty} \|\partial X_X\|_{L^2(v+z_1,\infty)} \left( \int_{z_1+v}^{+\infty} e^{2\alpha \beta^2 u v t \left( \frac{1}{u^2+v^2} - \frac{1}{v^2} \right)} du \right)^{1/2} dv$$

$$\leq c \left( \int_0^{+\infty} \left( \int_{z_1+v}^{+\infty} e^{-\frac{2\alpha \beta^2}{v^2} u v t} du \right)^{1/2} \right) dv$$

$$\leq ct^{-1/2} \int_0^{+\infty} v^{-1/2} e^{-\frac{2\alpha \beta^2}{v^2} (z_1+v)t} dv$$

$$\leq ct^{-3/4}.$$  \hfill (9.26)

The bound for $I_2$ could be attained with the same method as for $I_1$. For $I_3$ we proceed as with (9.13) applying the Hölder’s inequality with $2 < p < 4$

$$I_3 = \int_0^{+\infty} \int_{z_1+v}^{+\infty} \left( (u - z_1)^2 + v^2 \right)^{-1/4} e^{\alpha \beta^2 u v t \left( \frac{1}{u^2+v^2} - \frac{1}{v^2} \right)} du dv$$

$$\leq \int_0^{+\infty} \left\| (u - z_1)^2 + v^2 \right\|_{L^p} \left( \int_{z_1+v}^{+\infty} e^{q \alpha \beta^2 u v t \left( \frac{1}{u^2+v^2} - \frac{1}{v^2} \right)} du \right)^{1/q} dv$$

$$\leq c \left( \int_0^{+\infty} v^{1/p-1/2} \left( \int_{z_1+v}^{+\infty} e^{-\frac{q \alpha \beta^2}{v^2} u v t} du \right)^{1/q} dv \right) \hfill (9.27)$$

$$\leq ct^{-1/q} \int_0^{+\infty} v^{2/p-3/2} e^{-\frac{q \alpha \beta^2}{v^2} (z_1+v)t} dv$$

$$\leq ct^{-3/4} \int_0^{+\infty} e^{-\frac{q \alpha \beta^2}{v^2} u v t} du \leq ct^{-3/4},$$

where we use the substitution $w = t^{1/2}v$ and the fact that $-1 < 2/p - 3/2 < -1/2$. \hfill \Box

## 10 Large time asymptotic behavior for the FL equation

Now we begin to construct the long-time asymptotics of the FL equation (1.2). Inverting the sequence of transformations (5.11), (5.35), (5.47) and (5.54), we have

$$M(k) = M^{(3)}(k)E(k)M^{(out)}(k)R^{(2)}(k)^{-1}T(k) \sigma_3, \quad k \in \mathbb{C} \setminus U_{k_0},$$  \hfill (10.1)

where $T(k) \sigma_3$ is a diagonal matrix.

To reconstruct the solution $u_x(x,t)$, we take $k \to \infty$ along the straight line $k \in D_{12} \cup$
$D_{22} \cup D_{35} \cup D_{45}$, which means $R^{(2)}(k) = I$. From (5.7), (6.45), (8.11) and (9.14), we have
\[
M = (I + \frac{M^{(3)}_1}{k} + \ldots)(I + \frac{E_1}{k} + \ldots)(I + \frac{M^{(\text{out})}_1}{k} + \ldots)(I + \frac{T^{\sigma_3}_1}{k} + \ldots),
\]
which means the coefficient of the $k^{-1}$ in the Laurent expansion of $M$ is
\[
M_1 = M^{(3)}_1 + E_1 + M^{(\text{out})}_1 + T^{\sigma_3}_1.
\]

We construct the solution $u(x,t)$ of (1.2) with initial data $u_0$ by the transformation and the final result is as follows:

**Theorem 2.** Assume that $u(x,t)$ be the solution for the initial-value problem (1.2)-(1.3) with the appropriate generic data $u_0(x)$. For fixed $x_1, x_2, v_1, v_2 \in \mathbb{R}$ with $x_1 \leq x_2$ and $v_1 \leq v_2 \in \mathbb{R}^-$, we define two zones for the spectral variable $k$
\[
\mathcal{I} = \{k : f(v_2) < |k| < f(v_1)\},
\]
with
\[
\mathcal{K}(\mathcal{I}) = \{k_j \in \mathcal{K} : k_j \in \mathcal{I}\}, \quad \mathcal{N}(\mathcal{I}) = |\mathcal{K}(\mathcal{I})|,
\]
and a cone for variables $x,t$
\[
\mathcal{C}(x_1, x_2, v_1, v_2) = \{(x, t) \in \mathbb{R}^2 | x = x_0 + vt, \text{ with } x_0 \in [x_1, x_2], v \in [v_1, v_2]\}
\]
as is shown in Figure 9. Denote $m_{sol}(x,t|\mathcal{D}(\mathcal{I}))$ be the $\mathcal{N}(\mathcal{I})$-soliton solution corresponding to the scattering data $\{k_j, c_j\}_{j=1}^{\mathcal{N}(\mathcal{I})}$ which is given in (6.23). Then as $t \to \infty$ with $(x,t) \in \mathcal{C}(x_1, x_2, v_1, v_2)$, from (3.7), (6.45), (8.14) and (9.21) we have
\[
m(x,t) = m_{sol}(x,t|\mathcal{D}(\mathcal{I})) + t^{-1/2} f(x,t) + \mathcal{O}(t^{-3/4}).
\]
Thus
\[
|m(x,t)|^2 = |(m_{sol}(x,t|\mathcal{D}(\mathcal{I})) + t^{-1/2} f(x,t) + \mathcal{O}(t^{-3/4}))|^2
\]
\[
= |m_{sol}(x,t|\mathcal{D}(\mathcal{I}))|^2 + 2t^{-1/2} f(x,t)m_{sol}(x,t|\mathcal{D}(\mathcal{I})) + \mathcal{O}(t^{-3/4}).
\]

Based on the above discussion we can obtain
\[
u_x(x,t) = \left(m_{sol}(x,t|\mathcal{D}(\mathcal{I})) + t^{-1/2} f(x,t) + \mathcal{O}(t^{-3/4})\right) e^{-i \int x^- |m|^2 dx'},
\]
where $f(x,t)$ has been established in (8.15).
A $\bar{\partial}$-steepest descent analysis for large negative times

The steps in the steepest descent analysis of RH Problem 3.1 for $t \to -\infty$ mirror those presented in Sections 3-10 for $t \to \infty$. The differences that appear can be traced back to the fact that the regions of growth and decay of the exponential factors $e^{2it\theta}$ are reversed when one considers $t \to -\infty$, as Figure 12 shows. In this part, we briefly sketch those changes, leaving the detailed calculations to the interested reader.

![Figure 12: In the shaded regions, $|e^{it\theta}| \to 0$ when $t \to \infty$, while, in the blank regions, $|e^{-it\theta}| \to 0$ when $t \to \infty$.](image)

The first step in the analysis, as in Section 3, is a conjugation to well-condition the problem for large-time analysis. Similar to (5.11) define

$$M^{(1)}(k) = M(k)T(k)^{-\sigma_3}$$ (A.1)

$T(k)$ can be defined in Proposition 9 with $t < 0$. Non-analytic extensions of the jump matrices (5.13) are introduced to deform jump matrices onto contours along which they decay to the identity as was done in Section 4 whose contours and domains are shown below.

Accordingly, the definition of $R_j$ is also slightly different from $t > 0$, i.e., we exchange the definition of $R_j$ on the two sides of steady-state phase points on the real and the imaginary
axis. Once the functions are constructed, the transformation
\[ M^{(2)}(k) = M^{(1)}(k)R(k). \] (A.2)

where \( R(k) \) is defined in each sector in Figure 11. We define a new unknown \( M^{(2)}(k) \) which satisfies

**RH Problem A.1.** Find a function \( M^{(2)}(k) = M^{(2)}(k; x, t) \) with the following properties.

(a) **Analyticity:** \( M^{(2)}(k) \) is continuous in \( \mathbb{C} \), has sectionally continuous first partial derivatives in \( \mathbb{C} \backslash (\Sigma^{(2)} \cup K \cup \overline{K}) \), and meromorphic in \( D_{n2} \cup D_{n5} \), \( n = 1, 2, 3, 4 \);

(b) **Symmetry:** \( M^{(2)}(k) = \sigma_2 M^{(2)}(k) \sigma_2 \);

(c) **Jump condition:** The boundary value \( M^{(2)}(k; x, t) \) at \( \Sigma^{(2)} \) satisfies the jump condition
\[ M^{(2)}_+(k) = M^{(2)}_-(k)V^{(2)}(k), \quad k \in \Sigma^{(2)}; \] (A.3)

(d) **Asymptotic condition**
\[ \begin{cases} 
M^{(2)}(k) = I + \mathcal{O}(k^{-1}), & k \to \infty, \\
M^{(2)}(k) = e^{-\frac{2}{\epsilon_0}\sigma_3 (I + kU + \mathcal{O}(k^2))} e^{\frac{2}{\epsilon_0}\sigma_3}, & k \to 0;
\end{cases} \] (A.4)

(e) Away from \( \Sigma^{(2)} \) we have
\[ \overline{\partial} M^{(2)}(k) = M^{(2)}(k) \overline{\partial} R^{(2)} \] (A.5)

holds in \( \mathbb{C} \backslash \Sigma^{(2)} \), where
\[ \overline{\partial} R^{(2)}(k) = \begin{cases} 
\frac{1}{(1)^j} \overline{R}_{n,j}(k)e^{2it\theta} & 1, \quad k \in D_{nj}, \ n = 1, 2, 3, 4; \ j = 1, 4; \\
1 & 1, \quad k \in D_{nj}, \ n = 1, 2, 3, 4; \ j = 3, 6; \\
0 & 0, \quad k \in D_{nj}, \ n = 1, 2, 3, 4; \ j = 2, 5;
\end{cases} \] (A.6)

(f) **Residue conditions:** \( M^{(2)} \) has simple poles at each point in \( K \cup \overline{K} \) with:
\[ \begin{align*}
\text{Res}_{k=k_j} M^{(2)}(k) &= \lim_{k \to k_j} M^{(2)}(k)R_{k_j,\mp}, & k \in \Delta_{k_0}^\pm, \\
\text{Res}_{k=\overline{k}_j} M^{(2)}(k) &= \lim_{k \to \overline{k}_j} M^{(2)}(k)\sigma_2 R_{\overline{k}_j,\mp} \sigma_2, & k \in \Delta_{\overline{k}_0}^\pm.
\end{align*} \] (A.7)

where \( R_{k_j,\mp} \) and \( R_{k_j,\mp} \) is defined in (5.17).
Mimicking Sections 5–10, the final steps of the analysis are to first construct a solution $M^{rhp}(k)$ of the RH components of RH problem A.1, and then to use the solid Cauchy integral operator to prove that the remainder $M^{(3)}(k) = M^{(2)}(k)(M^{rhp})^{-1}(k)$ is uniformly near the identity with estimates identical to (9.21). When $t \to -\infty$ with $(x,t) \in \mathcal{C}(x_1,x_2,v_1,v_2)$, the outer model takes the form

$$M^{(\text{out})}(k) = \left[ I + \mathcal{O}(e^{-4\mu t}) \right] m^{\Delta_{k_0}}(\mathcal{I}) \left( k \mid D^-(\mathcal{I}) \right)$$  \hspace{1cm} (A.9)

The local model $M^{(\text{in})}$ is constructed as in Section 8. Define

$$N : f(k) \to (Nf)(k) = f\left( \frac{k_0^2}{2\sqrt{\alpha \beta}} e^{-\frac{t}{2}} \zeta - z_3 \right).$$  \hspace{1cm} (A.10)

Then the local model $M^{(\text{in})}$ is given by

$$M^{(\text{in})}(k) = M^{(\text{out})}(k)\sigma_3 M^f(-\zeta(k))\sigma_3$$

where $M^f(\zeta, r)$ is the solution of RH Problem 8.1. The residual error $E(k)$ now satisfies RH Problem 9.1 but with (8.4) now given by

$$V^{(E)}(k) = \begin{cases} M^{(\text{out})}(k)V^{(2)}(k)M^{(\text{out})}(k)^{-1}, & k \in \Sigma^{(2)} \setminus \sum_{n=1}^{4} U_{z_n}, \\ M^{(\text{out})}(k)\sigma_3 M^f(-\zeta(k))\sigma_3 M^{(\text{out})}(k)^{-1}, & k \in \sum_{n=1}^{4} \partial U_{z_n}. \end{cases}$$  \hspace{1cm} (A.11)

The small-norm theory again can be used to show that $E(k)$ exists and satisfies

$$E(k) = I + k^{-1} E_1 + \mathcal{O}(k^{-2}),$$  \hspace{1cm} (A.12)

with

$$E_1 = -\frac{1}{2\pi i} \oint_{\sum_{n=1}^{4} \partial U_{z_n}} V^{(E)}(s) - I \ ds + \mathcal{O}(t^{-1})$$

$$= \frac{k_0^2}{2i\beta \sqrt{\alpha t}} \sum_{n=1}^{4} (-1)^{n+1} M^{(\text{out})}(z_n) M^{pc}(z_n) M^{(\text{out})}(z_n)^{-1} + \mathcal{O}(t^{-1}).$$  \hspace{1cm} (A.13)

The rest of the results can be given in the same way as showed in Section 11.

**B The parabolic cylinder model**

Here we describe the solution of the parabolic cylinder model problem introduced by Its [2], which was later widely used to study the long-time asymptotics of integrable systems in

65
the literature [3, 33]. For our FL equation, there are two phase points \( z_1, z_3 \in \mathbb{R} \) and two \( z_2, z_4 \in i\mathbb{R} \) respectively, which need two kinds of parabolic cylinder models to describe.

Therefore, for \( r_0 \in \mathbb{R} \), define

\[
\nu = \nu(r_0) = -\frac{1}{2\pi} \ln(1 + \varepsilon_n |r_0|^2),
\]

where \( \varepsilon_n = 1 \), for \( n = 1, 3; \varepsilon_n = -1 \), for \( n = 2, 4 \). Further define contours

\[
\Sigma^{pc} = \bigcup_{j=1}^4 \Sigma_j, \quad \Sigma_j = \{ \zeta = \mathbb{R}^+ e^{i(2j-1)\pi/4}, j = 1, 2, 3, 4 \}.
\]

Then we have the following parabolic cylinder model problem.

**RH Problem B.1.** Find a \( 2 \times 2 \) matrix-valued function \( M^{pc}(\zeta, r_0) \) with the following properties:

(a) \( M^{pc}(\zeta, r_0) \) is analytic for \( \mathbb{C} \backslash \Sigma^{pc} \);

(b) The boundary value \( M^{pc}(\zeta, r_0) \) at \( \Sigma^{pc} \) satisfies the jump condition

\[
M^+_{pc}(\zeta, r_0) = M^-_{pc}(\zeta, r_0)V^{pc}(\zeta), \quad \zeta \in \Sigma^{pc}, \tag{B.1}
\]

where

\[
V^{pc}(\zeta) = \begin{cases}
1 & \quad \zeta \in \Sigma_1, \\
1 & \quad \zeta \in \Sigma_2, \\
1 & \quad \zeta \in \Sigma_3, \\
1 & \quad \zeta \in \Sigma_4.
\end{cases}
\]
It can be shown that the RH Problem B.1 admits a solution
\[ M^{pc}(\zeta, r_0) = I + \frac{M^{pc}(r_0)}{i\zeta} + O(\zeta^{-2}) \]  
where
\[ M^{pc}_1(r_0) = \begin{pmatrix} 0 & \beta_{12} \\ -\beta_{21} & 0 \end{pmatrix}, \]
with \( \beta_{12} \) and \( \beta_{21} \) being two complex constants
\[ \beta_{12} = \frac{\sqrt{2\pi} e^{i\pi/4} e^{-\pi/2}}{r_0 \Gamma(-i\nu)}, \quad \beta_{21} = -\frac{\sqrt{2\pi} e^{-i\pi/4} e^{-\pi/2}}{\varepsilon_n r_0 \Gamma(i\nu)}. \]
