ABSTRACT

Background: Staphylococcus pseudintermedius is an opportunistic pathogen that is the major cause of pyoderma affecting dogs. Conventional antimicrobial treatment for infections caused by this organism have failed in recent years due to widespread resistance and alternative treatment strategies are a high priority. Protein A encoded in Staphylococcus aureus by spa protects the bacterium by binding IgG and acts as a superantigen. Staphylococcus pseudintermedius possess two genes orthologous to S. aureus spa, spsP, and spsQ.

Methods: SpsQ and SpsQ-M, a non-toxigenic SpsQ, were cloned and expressed as recombinant proteins and their cytotoxic effect on canine B cells was measured. The neutralizing ability of antibody raised against them in clinically healthy dogs was evaluated.

Results: S. pseudintermedius SpsQ induced apoptosis of canine B cells. Specific amino acid substitutions diminished SpsQ-M binding to immunoglobulin and its super-antigenic activity, while its antigenicity was maintained. This recombinant, non-toxigenic S. pseudintermedius SpsQ stimulated the production of antibodies in dogs that specifically reacted with SpsQ and greatly diminished its cytotoxic effect on canine B cells.

Conclusions: The production of neutralizing antibody suggests that attenuated, non-toxic SpsQ produced in this study is a good candidate for inclusion in a vaccine for use in the treatment and prevention of S. pseudintermedius infections.

Abbreviations: SpA: Staphylococcus aureus protein A; SpP: Staphylococcus pseudintermedius protein A; SpQ: Staphylococcus pseudintermedius protein A; MRSP: methicillin resistant Staphylococcus pseudintermedius; IgA: immunoglobulin A; IgG: immunoglobulin G; IgM: immunoglobulin M; VH: variable region of immunoglobulin heavy chain; IgBD: immunoglobulin binding domains; MFI: mean fluorescent intensity; SEM: standard error of the mean; PBMC: Peripheral blood mononuclear cells; CD21: complement receptor type 2; ST: Sequence type; OD: Optical density; ORF: open reading frame; PBS: Phosphate buffered saline; Tween 20: Polyethylene glycol sorbitan monolaurate 20; HRP: horseradish peroxidase; TMB-3,3',5,5'-Tetramethylbenzidine

Introduction

Staphylococcus pseudintermedius, a gram-positive, coagulase-positive bacterium, is commonly found on the normal skin and nasal flora of household pets [1,2]. It is the major cause of canine skin and ear infections [2,3]. Furthermore, human infections are sporadically reported [4,5], suggesting that, although it is estimated to be low, there is a threat of zoonotic disease. Approximately 30–35% of the S. pseudintermedius isolates tested in our University of Tennessee College of Veterinary Medicine Clinical Bacteriology Laboratory are methicillin-resistant. Methicillin resistant S. pseudintermedius (MRSP) are resistant to most antimicrobial agents accessible at present and the number of multidrug resistant staphylococcal isolates is increasing [6–9].

Alternative approaches to antimicrobial therapy to treat staphylococcal infections, such as vaccines, have been difficult to develop. This is likely rooted in the ability of the bacteria to evade and/or destroy important components of their host defenses [10,11]. Protein A is anchored on the peptidoglycan cell wall and is also secreted during the exponential growth phase [12–15]. It is an important virulence factor, able to bind IgG via its Fc region [16–18] protecting staphylococci from opsonophagocytosis. It also binds to and crosslinks the VH3-family of immunoglobulin idiotypes (the Ig fragment responsible for antigen recognition), triggering apoptosis [19,20]. Consequently, protein A plays an
important role in enhancing pathogenicity of staphylococci by impairing the development of the host immune response [10,21]. Recently, it has been demonstrated that immunization with nontoxigenic \textit{S. aureus} protein A (SpA<sub>KAAA</sub>) (with amino acid substitutions in five repeated domains, E, D, A, B, and C) protected guinea pigs in experimental models of \textit{S. aureus} infection [22]. Also, \textit{S. aureus} expressing the mutant variant was deficient in abscess formation, and laboratory animals infected with these mutant bacteria overcame the immunosuppressive effects of protein A and developed adaptive immune responses [22]. Likewise, Pankey et al. [23] investigated the use of \textit{S. aureus} protein A (SpA) as a vaccine for bovine mastitis with promising results.

In vertebrates, the immunoglobulin variable region of the heavy chain (VH) is encoded by diverse genes and the VH differ in length and amino acid composition between species and each species has its own repertoire [24–26]. In dogs, the VH1-family of immunoglobulin idiotypes represent the largest portion of VH genes in B cell populations [25].

Previous studies on SpA [27] have demonstrated that SpA binds to the Fab portion of VH3-type IgM on the surface of B cells resulting in cross-linking of B cell receptors that lead to B cell clonal expansion and subsequent apoptotic collapse, thereby limiting the host’s capability to produce antibody to other staphylococcal antigens [21].

In 2011, Bannoehr et al. [28] found that \textit{S. pseudintermedius} possess two genes orthologous to \textit{S. aureus} spa, spsP (encoding SpsP) and spsQ (encoding SpsQ, analogous to SpA). Balachandran et al. [18] recently found that SpsP and SpsQ consist of approximately 377 and 462 amino acids, respectively. Both proteins have predicted N-terminal sequences of 33 amino acids, followed by a repeat region of three or four IgG-binding domains and a C terminal region that shares about 63% sequence similarity to the X-region of \textit{S. aureus}. The Immunoglobulin-binding domains (IgBDs) are highly conserved between SpsP and SpsQ, with amino acid sequence identity ranging from 67 to 90%. Balachandran et al. [18] found that spsQ was present in all clinical isolates of \textit{S. pseudintermedius} tested within diverse multilocus sequence types, although they had different levels of expression, whereas spsP was less conserved and often occurs in degenerate form. They showed that \textit{S. pseudintermedius} SpsQ is cell wall anchored and was detected in the bacterial secretome during log phase [18]. SpsQ bound to canine IgG primarily via its Fc region [18]. This interaction was inhibited by anti-SpA raised in chickens which made \textit{S. pseudintermedius} more susceptible to phagocytosis [18]. Grandolfo [29] suggested that \textit{S. pseudintermedius} SpsQ could be considered a possible vaccine target, however, information about SpsQ is scarce and it is necessary to determine if there are toxic effects of \textit{S. pseudintermedius} protein A on canine B cells that can be neutralized with antibody.

The purpose of this study was to characterize the cytotoxic effect of recombinant \textit{S. pseudintermedius} SpsQ on dog B cells, develop attenuated SpsQ (SpsQ-M), and evaluate antibody raised against SpsQ-M in clinically healthy dogs. \textit{Staphylococcus pseudintermedius} SpsQ-M was tested for its antigenicity and B cell killing. The results from this study suggest that \textit{S. pseudintermedius} SpsQ may serve as a key component in a vaccine or as part of an immunotherapeutic treatment.

**Results**

**Bioinformatics analysis and \textit{S. pseudintermedius} protein A characteristics**

\textit{S. pseudintermedius} ED99, representing isolate that expresses both SpsQ and SpsP, SpsQ contained four and SpsP had genes encoding a maximum of three Ig-binding domains (Figure 1(a)). This compares to five domains with AA identities of 74% in \textit{Staphylococcus aureus subsp. aureus} strain \textit{Newman} SpA (Figure 1(b)). Three out of four SpsQ domains share 84–88% identity with the C domain of \textit{S. aureus} SpA with threonine at position 19, while only one domain is more similar to the B domain of \textit{S. aureus} SpA (Figure 1(c)).

Multiple sequence alignment (MSA) between each domain of SpsQ and domain C of SpA, the most similar domain to SpsQ IgBDs, showed that each domain in SpsQ has binding sites for the IgG Fcγ (Glutamine (Q) and D, and Fab region (aspartate (D) and D) of surface membrane-associated variable heavy 1 (VH1)-encoded B cell antigen receptors (Figure 1(c)). Furthermore, as with SpA of \textit{S. aureus}, the secondary structure of SpsQ consists only of alpha helices and each Ig binding domain consists of three helices (Figure 1(d)).

**Cloning, expression, and purification of recombinant SpsQ and SpsQ-M**

Recombinant polyhistidine tagged SpsQ and SpsQ-M were produced in \textit{E.coli} and purified using HisPur Ni-NTA resin under native conditions and eluted using an imidazole gradient. The molecular weights of SpsQ and SpsQ-M determined in western blots were of the expected sizes (47.2 and 47.6 kDa, respectively) (Figure 2).
Antigenicity of SpsQ and SpsQ-M and their reactivity with serum from a dog with pyoderma

Chicken anti-protein A, chosen because protein A does not bind chicken immunoglobulin, had strong reactivity with affinity-purified SpsQ-M similar to that with S. aureus SpA and S. pseudintermedius SpsQ, indicating the attenuated protein retained its antigenicity (Figure 3). Sera from a dog with a history of chronic pyoderma showed significantly lower reactivity against SpsQ-M.
Figure 2. Western blot of recombinant *S. pseudintermedius* wild and mutant protein A with HRP-conjugated anti-6xhis tag monoclonal antibody. SpsQ and SpsQ-M were expressed in E.coli with M.W. of 47.2 and 47.6 KDa, respectively.

Figure 3. HRP-conjugated chicken anti-protein A recognizes and binds to recombinant SpsQ, SpsQ-M and commercial *S. aureus* SpA. The values represent averages from three independent experiments. (*P < 0.05 was considered significant). There was no statistically significant difference between any sample P > 0.05 (ns).

**SpsQ-M induces specific antibody responses in dogs that reduce the effect of SpsQ on B cells in vitro**

ELISA analysis of sera obtained from dogs on days −7, 8, 15 and 29 (relative to injections) showed that antibodies against *S. pseudintermedius* SpsQ-M and SpA were detected on day 15 and reached the highest level on day 29 (P < 0.0001) compared to pre-injection control sera (Figure 6(a,b)).

Pre-incubation of SpsQ, at a concentration of 100 µg/ml in PBS with dog anti-SpsQ-M resulted in 105,665 ± 900.3 SEM, n = 1 reduction in annexin mean fluorescent intensity (MFI) as compared with that of SpsQ treatment alone (Figure 7).

**Discussion**

Protective host immune responses against extracellular pathogens are typically antibody-mediated. Unfortunately, staphylococcal infection does not usually establish protective immunity [24,30–32] and efficacious staphylococcal vaccines have proven difficult to develop. Most vaccine research has focused on *S. aureus*, which most commonly affects humans and is distinguished from *S. pseudintermedius*, which is primarily of veterinary concern.

Two forms of *S. pseudintermedius* protein A contain IgBDs that are similar to each other and likely to be antigenically cross-reactive. Because of their similarity and the presence of SpsQ in all tested isolates, SpsQ was used for this study. Understanding how *S. pseudintermedius* subverts the canine immune response is important for vaccine development and to facilitate natural host humoral immunity.

*S. pseudintermedius* SpsQ binding with the Fab region of surface membrane-associated VH1-encoded B-cell antigen receptors induces apoptosis in canine B cells. We developed a non-toxigenic SpsQ (SpsQ-M) by substitution of residues responsible for dual reactivity of each SpsQ domain with IgG Fc and Fab regions of surface membrane-associated VH1-encoded B-cell antigen receptors. Compared to staphylococcal protein A [33], SpsQ-M had much lower reactivity with IgG. Moreover, IgG, IgM, and IgA in sera from a dog with a history of chronic pyoderma had little immune-mediated binding to SpsQ-M indicating a lack of natural production of antibody elicited by infection with *S. pseudintermedius*. Comparing purified recombinant wild-type and mutant

**S. pseudintermedius protein A induced apoptosis of canine B cells**

Affinity-purified SpsQ-M had a low apoptotic effect on B cells at 1.5 h in contrast to recombinant SpsQ at the same time point, with a mean ± SEM fluorescent intensity (MFI) difference of 2052 ± 285.2 between SpsQ and SpsQ-M (p-value of 0.0063) (Figure 5(a)). Incubation of the cells for 3.5 h with SpsQ-M resulted in a Sytox MFI reduction of 519,065 ± 128,292 SEM compared to that of SpsQ (p-value of 0.0003) (Figure 5(b)).
SpsQ, we found SpsQ-M had a significantly lower toxic effect on canine B lymphocytes. These results are in agreement with the findings of Kim et al. with S. aureus SpA(KKAA) as determined using mouse B lymphocytes and human immunoglobulins.

It should be noted that specific antibody directed against native protein A cannot be measured due to the non-immune binding of protein A to immunoglobulin. After injecting a clinically healthy dog with SpsQ-M, we observed a high titer of SpsQ-specific antibodies in agreement with Kim et al’s observations with SpAKKAA injected in mice. These results indicate that SpsQ, similar to SpA, suppresses adaptive immune responses during staphylococcal infection which may explain why previous S. pseudintermedius infections are not associated with protective immunity against recurrent infection.

Dog anti-SpsQ-M abolished the superantigenic effect of SpsQ that triggers apoptotic cell death in canine B cells, consistent with the findings of others with SpA studied in non-canine systems.

Collectively, the use of SpsQ-M will improve our understanding of the immune interactions between S. pseudintermedius and the dog. Data presented in our study suggest that blocking the Fcγ and Fab binding activities of SpsQ could be an alternative or adjunct to conventional antimicrobial treatments for infections caused by S. pseudintermedius including canine pyoderma. Canine anti-SpsQ-M may reduce SpsQ immune suppression in dogs, stimulate the production of specific antibodies against S. pseudintermedius and establish a protective immunity against recurrent infection. A SpsQ-M vaccine would likely contain additional S. pseudintermedius virulence factors.

**Figure 4.** Natural infection with S. pseudintermedius did not elicit antibody specifically reactive with staphylococcal protein A. Serum from a dog with a history of chronic pyoderma showed significantly lower reactivity with SpsQ-M compared to wild type SpsQ and SpA for (a), IgG, (b), IgM and (c), IgA (p-value of 0.0001 for each) ****. The values represent averages from three independent experiments. (*P < 0.05 was considered significant). ns – Not significant.
Material and methods

Ethics Statement

Experimental protocols were reviewed and approved by the University of Tennessee Institutional Animal Care and Use Committee (IACUC) including obtaining blood samples of dog (2474–0716) and injecting dogs with recombinant protein for producing antibodies (2572–1217).

Bioinformatics analysis

MSA of \( \text{spsQ} \) from diverse isolates of \( S. \text{pseudintermedius} \) (\( n = 100 \)), was performed using Geneious, version 9.1.3[34]. The bacterial localization prediction tool, PSORTb version 3.0.2 (http://www.psort.org/psortb/) [35], was used to determine the topology and domain structure of \( \text{SpsQ} \) and \( \text{SpsP} \). \( \text{SpsQ} \) modeling and binding site prediction were performed using Protein

Figure 5. \( S. \text{pseudintermedius} \) recombinant \( \text{SpsQ} \) has a superantigenic effect on canine B cells. (a) Gating on canine peripheral blood mononuclear cells (PBMC) based on side and forward scatter (shown in dot plot) and on B cells using PE-anti-CD21 antibody (shown in density plot), \( \text{SpsQ} \) induced B cell apoptosis after 1.5 hr (violet peak on histogram) compared to \( \text{SpsQ-M} \) (yellow peak on histogram). The mean fluorescent intensity (MFI) of the blank, \( \text{SpsQ} \) and \( \text{SpsQ-M} \) relative to SpA was calculated based on average values from three independent experiments. (\( *P < 0.05 \) was considered significant). \( \text{ns} \) – Not significant. MFI of \( \text{SpsQ-M} \) was significantly lower (\( P = 0.0063 \)) ** than that of \( \text{SpsQ} \) and SpA. (b) Gating on canine B cells using PE-anti-CD21 antibody, \( \text{SpsQ} \) incubated for 3.5 hr, killed B cells (red peak) compared to \( \text{SpsQ-M} \) (violet peak on histogram). The MFI% of the blank, \( \text{SpsQ} \) and \( \text{SpsQ-M} \) relative to SpA was calculated based on average values from three independent experiments (\( *P < 0.05 \) was considered significant). \( \text{ns} \) – Not significant. MFI of \( \text{SpsQ-M} \) was significantly lower (\( P = 0.0003 *** \)) than that of \( \text{SpsQ} \) and SpA.
Homology/analogY Recognition Engine V 2.0 (Phyre2) (http://www.sbg.bio.ic.ac.uk/phyre2) [36], and the 3DLigandSite (http://www.sbg.bio.ic.ac.uk/3dligand_site/) [37], using SpA as a basis to predict the IgBDs in each domain. A pairwise sequence alignment of SpsQ and SpsP was used to identify conserved amino acids critical for IgG Fc and B cell receptor binding. Identification of IgBDs was guided by S. aureus SpA secondary structure [38] and based on S. aureus SpA residues [21] responsible for dual reactivity of each domain in SpA with Fcy [39] and Fab [40] and shared by S. pseudintermedius SpsQ.

Geneious, version 9.1.3 was used to select the locations for amino acids to be substituted in each IgBD and to design a full-length, four domain (SpsQ-M) attenuated S. pseudintermedius protein A construct (SpsQ-M). Glutamine (Q) 5 and 6, as well as aspartate (D) 32 and 33 in each domain of SpsQ were selected as critical amino acids for the association of SpsQ with immunoglobulin. To test this, substitutions of Q5K (lysine), Q6K, D32A (alanine), and D33A were introduced into each IgBDs of SpsQ.

**Bacterial strains and growth conditions**

The S. pseudintermedius strain used in this study, strain 06–3228 [41], was isolated at the University of Tennessee, College of Veterinary Medicine Bacteriology Laboratory. It represents the most common multilocus sequence type (ST) previously reported in the United States (ST68).
Bacterial colonies grown on blood agar plates were inoculated into 5ml of sterile trypticase soy broth (TSB) (BD Biosciences, San Jose, CA, USA Cat No. RS1-011–21) and incubated overnight at 37°C with shaking at 225 rpm (Excella E24 Incubator Shaker, New Brunswick Scientific). Fifty microliters of overnight culture were inoculated into 5ml of fresh, sterile TSB to initiate log-phase bacterial cultures. Bacteria were grown at 37°C with shaking at 225rpm until an optical density of OD600 = 0.4–0.6 was reached [43].

Cloning, expression, and purification of recombinant wild-type and non-toxigenic S. pseudintermedius SpSQ

Bacteria from a single colony of S. pseudintermedius strain 06–3228 obtained from blood agar plates were grown in TSB at 37°C with 225 rpm shaking. DNA was extracted using a MO BIO UltraClean® Microbial DNA Isolation Kit (QIAGEN Inc., USA Cat No.12224–50) according to the manufacturer’s instructions. Oligonucleotide primers (Integrated DNA Technology, Coralville, USA) (Table 1) were designed using a PrimerQuest Tool (https://www.idtdna.com/Primerquest/Home/Index) based on the whole genomic sequence of S. pseudintermedius strain 06–3228 determined by Riley et al [41].

The spsQ open reading frame (ORF) without the regions encoding the predicted N-terminal signal peptide was amplified from S. pseudintermedius 06–3228 genomic DNA. The ORF of spsQ-M was amplified from a PMA-SpsQ-M plasmid (Table 2) (Life Technologies Corp., Carlsbad, CA, USA), containing a synthetic spsQ-M gene. PCR was performed using taq polymerase (rTaq, Takara, USA Cat No. R004) and the following cycling conditions were performed: initial denaturation at 95°C for 90 seconds, 30 cycles of denaturation at 94°C for 30 seconds, annealing at 55°C for 30 seconds, and extension at 72°C for 1 minute followed by a final extension at 72°C for 5 minutes. All ORFs were amplified without a 6x histidine tag because pETBlue-2 (Table 2) allowed T7lac promoter-based expression of target genes with C-terminal histidine Tag sequences.

Table 1. Primers used to amplify recombinant wild and attenuated protein A (SpsQ) from Staphylococcus pseudintermedius. NotI and BamHI restriction sites are underlined.

Figure 7. Dog anti- spsQ-M antibody protects canine B cells from the superantigenic effects of SpSQ. Pre-incubation of SpSQ with dog anti-SpsQ-M resulted in mean 105,665 ± 900.3 SEM, n = 1 reduction in mean fluorescent intensity (MFI) from SpSQ on canine B cells compared to that of SpSQ treatment alone. a. Gating on canine peripheral blood mononuclear cells (PBMC) based on side and forward scatter (shown in dot plot) and (b) on B cells using PE-anti-CD21 antibody (shown in density plot). c. SpSQ induced B cell apoptosis after 1.5 hr (red peak on histogram) compared to SpSQ preincubated with dog serum at dilution 1:100 (blue peak on histogram).
PCR products were Sanger sequenced at The University of Tennessee Genomics Core facility.

To clone full length \textit{S. pseudintermedius} \textit{spsQ} and \textit{spsQ-M}, the PCR products were digested with \textit{NotI} and \textit{BamHI}, then ligated into pETBlue-2, an expression vector with C-terminal HSV\textsuperscript{Tag}\textsuperscript{*} and His\textsuperscript{Tag}\textsuperscript{*} sequences (Novagen, USA Cat No .70674). The pETBlue-2 construct transformed into DH5-alpha \textit{E. coli} chemically-competent cells (Table 2) (New England BioLabs Inc., USA Cat No .C29871) by heat shock and DH5-alpha bacteria were plated on LB agar plates with 100 µg/ml ampicillin. The plasmid constructs were transformed into Tuner\textsuperscript{™} (DE3) pLacI \textit{E. coli} chemically-competent cells (Table 2) (Novagen, USA Cat No .70623) by heat shock and the bacteria were plated on LB agar containing 50µg/ml ampicillin and 20µg/ml chloramphenicol.

To express recombinant protein, a single colony of Tuner\textsuperscript{™} (DE3) pLacI \textit{E. coli} was inoculated into LB broth containing 50µg/ml ampicillin and 20µg/ml chloramphenicol and bacteria were grown overnight at 37°C with 225 rpm shaking. LB broth containing 50µg/ml ampicillin and 20µg/ml chloramphenicol was inoculated with a 1:100 dilution of overnight culture and grown at 37°C with 225 rpm shaking until a 600 nm optical density between 0.4 and 0.6 was reached. Protein expression was induced by addition of 1 mM Isopropyl β-D-1-thiogalactopyranoside (IPTG) (Teknova, USA Cat. No. I3431) and bacteria were grown for 4 h at 30°C with shaking at 225 rpm. Bacterial cultures were centrifuged at 12,000 x g for 5 min in 5 ml of protein extraction reagent (BugBuster, Novagen, USA Cat No. 70,584) and 20 µl of 100X protease inhibitor (Cocktail Set III, EDTA-Free Calbiochem, USA Cat No. 539,134), and subsequently incubated for 30 min followed by centrifugation at 2,000 x g for 10 min in a refrigerated centrifuge.

**Production of antibodies against recombinant proteins**

Recombinant \textit{SpsQ-M} at 100 µg/ 0.5 cc in phosphate buffered saline (PBS) (pH 7.2) was injected in the lateral thorax by the subcutaneous route, into three clinically normal dogs. Injections were given once every 7 days for a total of three injections with a control dog receiving PBS (pH 7.2) only. Blood (6 cc) was collected from a jugular vein using a 20 g needle and 12 cc syringe 4 times, on days −7, 8, 15 and 29. The collected blood was left undisturbed at room temperature for 30 min followed by centrifugation at 2,000 x g for 10 min in a refrigerated centrifuge.

**SDS-PAGE and western blots**

Protein samples were resolved by SDS-PAGE in 4–12% polyacrylamide gels (Invitrogen, USA Cat No. NP0322BOX) and electrophoretically transferred unto nitrocellulose membranes (Thermo Scientific, USA Cat No. 77,010). The blots were blocked overnight in 5% (w/v) nonfat dried milk powder dissolved in phosphate buffered saline containing 0.05% polyethylene glycol sorbitan monolaurate (Tween 20) (PBS-T) at 4°C. The blocked membranes were incubated with a 1:2,000 dilution of horseradish peroxidase (HRP)-conjugated anti-6xhis tag monoclonal antibody (Thermo Scientific, USA Cat No. MA1-21,315-HRP) in 0.05% PBS-T for 1 h with 225 rpm shaking at room temperature. After five washes with 0.05% PBS-T, bound antibodies were detected using 1-Step™ chloronaphthol substrate solution (Thermo Scientific, USA Cat No. 34,012).

**Enzyme-linked immunosorbent assay**

For measurement of the antigenicity of recombinant proteins, affinity-purified SpsQ and SpsQ-M were coated on ELISA plates (Corning, USA Cat No. 3590) at 2 µg/ml in PBS (pH 7.2). The plates were washed with PBS-T and incubated with HRP- chicken anti-protein A antibody (Galus Immunotech, USA Cat No. APA) for 1 h at 37°C, then washed. For this and all subsequent ELISA assays, plates were washed three times with PBS-T between all incubations, bound antibodies were detected using TMB substrate (Thermo Scientific, USA Cat No. N301), reactions were stopped with 0.18 M sulphuric acid and optical density read at 450 nm on a plate reader (Bio TEK, USA Cat No. EL800). The experiment was repeated at least three times and a p-value of < 0.05 was considered significant, which was the same for all the experiments unless mentioned otherwise.

To test the reactivity of serum from a dog with chronic pyoderma, \textit{S. aureus} \textit{SpA} and \textit{S. pseudintermedius} \textit{SpsQ} and \textit{SpsQ-M} were coated on ELISA plates (Corning, USA Cat No. 3590) at 2 µg/ml in PBS. They were incubated with serum at a dilution of 1:2000. Bound IgG, IgM, and IgA were detected by HRP-goat anti-dog IgG-heavy and light chain (Bethyl Laboratories, Inc., USA Cat No. A40-123–1), HRP-goat anti-dog IgM µ chain (Bethyl Laboratories, Inc.,...
USA Cat No. A40-116–2), HRP-goat anti-dog IgA (Bethyl Laboratories, Inc., USA Cat No. A40-104P) at a dilution of 1:8000 in PBS-T. Dog whole IgG molecule (Rockland, USA Cat No. 004–0102-1000) was used for comparison to measure non-specific IgG binding.

To detect a specific antibody response against SpsQ-M in injected dogs, recombinant S. pseudintermedius proteins and commercial SpA were coated on ELISA plates as previously described and incubated with two-fold serially diluted serum from injected dogs (1/1000–1/32,000). Bound IgG was detected using HRP- goat anti-dog IgG-heavy and light chain (Bethyl Laboratories, Inc., USA Cat No. A40-123–1) with serum from un.injected dogs used as negative controls. The experiment was run in duplicate and a p-value of < 0.05 was considered significant.

The ability of S. pseudintermedius SpsQ to kill B cells and induce B cell apoptosis

A total of 100 µg of purified recombinant SpsQ or SpsQ-M was mixed with isolated peripheral blood mononuclear cells (PBMC) in 1 ml of RPMI medium supplemented with 10% fetal bovine serum and incubated for 1.5 h at 37°C in a 5% CO₂ incubator. To detect early phases of B cell apoptosis, phosphatidylserine was measured on the surface of cells using pacific blue- conjugated annexin (Thermo Scientific, USA Cat No. A35136). B cells were identified using phycoerythrin (PE) conjugated mouse anti-canine CD21 (clone: CA2.1D6) (BIO-RAD, USA Cat No. MCA1781PE) that recognizes canine CD21 (complement receptor type 2) on mature B lymphocytes. Stained B cells were analyzed using a flow cytometer (Attune acoustic focusing cytometer). B cells were also incubated with the same recombinant proteins as described above but for 3.5 h in order to detect B cell death. Cells were stained with Sytox green (Life Technologies, Inc., USA Cat No. 1,776,406) and PE-conjugated mouse anti-canine CD21. Gates were placed on cells positive for PE and these B cells were analyzed by flow cytometry.

To determine the protective effect of canine anti-SpsQ-M on B cells, recombinant S. pseudintermedius SpsQ was incubated for 30 minutes at 37°C with serum from SpsQ-M injected dogs. The experiment was run in duplicate and a p-value of < 0.05 was considered significant.

For flow cytometry analysis the cut-off for apoptosis or cell death was established using leukocytes incubated without SpsQ. Mean fluorescent intensity was determined from all B cells.

Statistical analysis

A one-way ANOVA and Tukey–Kramer method were used to measure the significant differences between SpsQ, SpsQ-M, and SpA on inducing apoptosis and causing B cell death. However, two-way ANOVA and Tukey–Kramer methods were performed to test if there were significant differences in SpA, SpsQ or SpsQ-M binding with canine antibodies. All analyzes were conducted using the GraphPad Prism software (Version 7, GraphPad Software Inc.).

Acknowledgments

This research was supported by Egyptian cultural and educational bureau, Washington DC and the University of Tennessee, Center of Excellence in Livestock Diseases and Human Health.

Disclosure statement

No potential conflict of interest was reported by the authors.

Funding

The authors declare no financial interest
