Abstract

The $R$-symmetry formalism is applied for the supersymmetric economical SU(3)$_C$ $\otimes$ SU(3)$_L$ $\otimes$ U(1)$_X$ (3-3-1) model. The generalization of the minimal supersymmetric standard model relation among $R$-parity, spin and matter parity is derived, and discrete symmetries for the proton stability in this model are imposed. We show that in such a case it is able to give leptons masses at just the tree level. A simple mechanism for the mass generation of the neutrinos is explored. With the new $R$-parity, the neutral fermions get mass matrix with two distinct sectors: one light which is identified with neutrino mass matrix, another heavy one which is identified with neutralinos one. The similar situation exists in the charged fermion sector. Some phenomenological consequences such as proton stability, neutrinoless double beta decays are discussed.

1 Introduction

Although the Standard Model (SM) gives very good results in explaining the observed properties of the charged fermions, it is unlikely to be the ultimate theory. It maintains the masslessness of the neutrinos to all orders in perturbation theory, and even after non-pertubative effects are included. The recent groundbreaking discovery of nonzero neutrino masses and oscillations [1] has put massive neutrinos as one of evidences on physics beyond the SM.

The Super-Kamiokande experiments on the atmospheric neutrino oscillations have indicated to the difference of the squared masses and the mixing angle with fair accuracy [2, 3]

$$\Delta m^2_{\text{atm}} = 1.3 \div 3.0 \times 10^{-3} \text{eV}^2,$$
$$\sin^2 2\theta_{\text{atm}} > 0.9. \quad (1.1)$$

While, those from the combined fit of the solar and reactor neutrino data point to

$$\Delta m^2_{\odot} = 8.0^{+0.6}_{-0.4} \times 10^{-5} \text{eV}^2,$$
$$\tan^2 \theta_{\odot} = 0.45^{+0.09}_{-0.07}. \quad (1.3)$$
Since the data provide only the information about the differences in $m_{\nu}^2$, the neutrino mass pattern can be either almost degenerate or hierarchical. Among the hierarchical possibilities, there are two types of normal and inverted hierarchies. In the literature, most of the cases explore normal hierarchical one in each. In this paper, we will mention on a supersymmetric model which naturally gives rise to three pseudo-Dirac neutrinos with an inverted hierarchical mass pattern.

The gauge symmetry of the SM as well as those of many extensional models by themselves fix only the gauge bosons. The fermions and Higgs contents have to be chosen somewhat arbitrarily. In the SM, these choices are made in such a way that the neutrinos are massless as mentioned. However, there are other choices based on the SM symmetry that neutrinos become massive. We know these from the popular seesaw [4] and radiative [5] models. Particularly, the models based on the $SU(3)_C \otimes SU(3)_L \otimes U(1)_X$ gauge unification group [6, 7, 8], called 3-3-1 models, give more stricter fermion contents. Indeed, only three fermion generations are acquired as a result of the anomaly cancelation and the condition of QCD asymptotic freedom. The arbitrariness in this case are only behind which SM singlets put in the bottoms of the lepton triplets? In some scenarios, exotic leptons may exist in the singlets. Result of this is quite similar the case of the SM neutrinos. As a fact, the mechanisms of the Zee’s type [5] for neutrino masses arise which been explored in Ref.[9].

Forbidding the exotic leptons, there are two main versions of the 3-3-1 models as far as minimal lepton sectors is concerned. In one of them [6] the three known left-handed lepton components for each generation are associated to three $SU(3)_L$ triplets as $(\nu_l, l, l^c)_L$, in which $l^c_L$ is related to the right-handed isospin singlet of the charged lepton $l$ in the SM. No extra leptons are needed and therefore it calls that a minimal 3-3-1 model. In the variant model [7] three $SU(3)_L$ lepton triplets are of the form $(\nu_l, l, \nu^c_l)_L$, where $\nu^c_l$ is related to the right-handed component of the neutrino field $\nu_l$, thus called a model with the right-handed neutrinos. This kind of the 3-3-1 models requires only a more economical Higgs sector for breaking the gauge symmetry and generating the fermion masses. It is interesting to note that two Higgs triplets of this model have the same $U(1)_X$ charges with two neutral components at their top and bottom. Allowing these neutral components vacuum expectation values (VEVs) we can reduce number of Higgs triplets to be two. Therefore we have a resulting 3-3-1 model with two Higgs triplets [10]. As a result, the dynamical symmetry breaking also affects lepton number. Hence it follows that the lepton number is also broken spontaneously at a high scale of energy. Note that the mentioned model contains very important advantage, namely, there is no new parameter, but it contains very simple Higgs sector, therefore the significant number of free parameters is reduced. To mark the minimal content of the Higgs sector, this version that includes right-handed neutrinos is called the economical 3-3-1 model.

Among the new gauge bosons in this model, the neutral non-Hermitian bilepton field $X^0$ may give promising signature in accelerator experiments and may be also the source of neutrino oscillations [11]. In the current paper, the neutrinos of the 3-3-1 model with right-handed neutrinos is a subject for extended study.

The 3-3-1 model with right-handed neutrinos gives the tree level neutrino mass spectrum

2
with three Dirac fermions, one massless and two degenerate in mass [12]. This is clearly not realistic under the experimental data. However, this pattern may be severely changed by quantum effects and gives rise to an inverted hierarchy mass pattern. This is a specific feature of the 3-3-1 model with right-handed neutrinos which was considered in Ref.[12] (see also [13]), but such effects exist in the very high level of the loop corrections.

The outline of this work is as follows. In Sec. 2 we define the $R$-charge in our model in order to get similar results as in the Minimal Supersymmetric Standard Model (MSSM). While in Sec. 3 we impose another discrete symmetry that allow neutrino masses but forbid the proton decay and the neutron-antineutron oscillation. In Sec. 4 we calculate the fermion masses in our model, then we present some phenomenological discussion of this model. Our conclusions are found in the last section. In Appendix A, we present the mass matrix elements of the neutral fermions.

## 2 Discrete $R$-parity in the supersymmetric economical 3-3-1 model (SUSYECO331).

In the supersymmetric 3-3-1 model with right-handed neutrinos (SUSY331RN) [14], the $R$-parity was already studied and we have shown that if $R$-symmetry is broken, the simple mechanism for the neutrinos mass can be constructed [15]. This mechanism produces the neutrinos mass which is in agreement with the experimental data.

The supersymmetric extension of the economical 3-3-1 model (SUSYECO331) was presented in [16]. The fermionic content of SUSYECO331 is the following: the left-handed fermions are in the triplets/antitriplets under the $SU_3$ group, namely, the usual leptons are the triplets $L_i = (\nu_i, l_i, \nu_i^c)_L \sim (1, 3, -1/3)$, $i = 1, 2, 3$; while in the quark sector, we have two families in the antitriplets $Q_{aL} = (d_a, u_a, D_a) \sim (3, 3^*, 0)$, $a = 1, 2$, and one family in the triplet $Q_{3L} = (u_3, d_3, T) \sim (3, 3, 1/3)$. The right-handed components are in the singlets under the $SU(3)_L$ group: $l_i^c \sim (1, 1, 1)$, $u_i^c \sim (3^*, 1, -2/3)$, $d_i^c \sim (3^*, 1, 1/3)$, which are similar to those in the SM. In addition, the exotic quarks transform as $T^c \sim (3^*, 1, -2/3)$, $D^c_\alpha \sim (3^*, 1, 1/3)$.

The scalar content is minimally formed by two Higgs triplets: $\chi = (\chi_1^0, \chi_2^0, \chi_3^0)^T \sim (1, 3, -1/3)$ and $\rho = (\rho_1^+; \rho_2^0; \rho_3^0)^T \sim (1, 3, 2/3)$. In order to cancel chiral anomalies in the SUSYECO331 model, we have to introduce the followings scalar Higgs triplets $\chi' = (\chi_1'^0, \chi_2'^0, \chi_3'^0)^T \sim (1, 3^*, 1/3)$ and $\rho' = (\rho_1'^-, \rho_2'^0; \rho_3'^0)^T \sim (1, 3^*, -2/3)$. In this model, the VEVs are defined by

$$\sqrt{2}\langle \chi \rangle^T = (u, 0, w), \quad \sqrt{2}\langle \chi' \rangle^T = (u', 0, w'), \quad (2.1)$$

$$\sqrt{2}\langle \rho \rangle^T = (0, v, 0), \quad \sqrt{2}\langle \rho' \rangle^T = (0, v', 0). \quad (2.2)$$

The VEVs $w$ and $w'$ are responsible for the first step of the symmetry breaking, while $u$, $u'$ and $v$, $v'$ are responsible for the second one. Therefore, they have to satisfy the constraints:

$$u, u', v, v' \ll w, w'. \quad (2.3)$$
The complete set of fields and the full lagrangian of SUSYECO331 are given in Ref. [16]. The most general superpotential is given by:

\[ W = \frac{W_2}{2} + \frac{W_3}{3}, \]

where

\[ W_2 = \mu_0 \hat{L}_i L \hat{\chi}' + \mu_\chi \hat{\chi}' \hat{\chi} + \mu_\rho \hat{\rho}', \]

and

\[
W_3 = \gamma_{\alpha\beta} \hat{L}_i L \hat{\rho}_{\beta\gamma}' \hat{c}_{\alpha\gamma} + \lambda_{\alpha\beta} \hat{L}_i L \hat{\phi} + \lambda'_{\alpha\beta} \hat{L}_i L \hat{\rho}' \hat{\phi}
+ \kappa_{\alpha} \hat{Q}_1 L \hat{\chi}' \hat{c}_{\alpha} + \kappa'_{\alpha} \hat{Q}_1 L \hat{\chi}' \hat{c}_{\alpha} + \hat{\pi}_1 \hat{Q}_1 L \hat{\rho}' \hat{\phi}
+ \hat{\pi}'_1 \hat{Q}_1 L \hat{\rho}' \hat{\phi}
+ \Pi_{\alpha\beta} \hat{Q}_1 L \hat{\chi} \hat{d}_{\beta\gamma} + \Pi'_{\alpha\beta} \hat{Q}_1 L \hat{\chi} \hat{d}_{\beta\gamma} + \epsilon \hat{\pi}_{\alpha\beta} \hat{Q}_1 L \hat{\phi} \hat{Q}_1 L \hat{\phi}
+ \xi_{i\beta\gamma} \hat{c}_{i\beta} \hat{d}_{\gamma} \hat{u}_L + \xi_{i\beta\gamma} \hat{c}_{i\beta} \hat{d}_{\gamma} \hat{u}_L + \xi_{i\beta\gamma} \hat{c}_{i\beta} \hat{d}_{\gamma} \hat{u}_L
+ \xi_{i\beta\gamma} \hat{c}_{i\beta} \hat{d}_{\gamma} \hat{u}_L
+ \xi_{\alpha\beta} \hat{L}_i \hat{\phi} \hat{d}_{\beta\gamma} + \xi'_{\alpha\beta} \hat{L}_i \hat{\phi} \hat{d}_{\beta\gamma}.
\] (2.6)

The coefficients \( \mu_0, \mu_\rho \) and \( \mu_\chi \) have mass dimension and can be complex variables [17], while all coefficients in \( W_3 \) are dimensionless, and \( \lambda'_{\alpha\beta} = -\lambda'_{\beta\alpha} \).

Let us impose the \( R \)-parity as the same as that of the minimal supersymmetric standard model. In this case, we have to choose the following \( R \)-charges

\[
\begin{align*}
n_\chi &= n_{\chi'} = n_\rho = n_{\rho'} = 0, \\
n_L &= n_{Q_\alpha} = n_{Q_3} = 1/2, \\
n_t &= n_u = n_d = n_T = n_D = -1/2.
\end{align*}
\] (2.7)

The superpotential satisfying the above \( R \)-parity conservation is written as

\[
W_{RC} = \frac{\mu_\chi}{2} \hat{\chi}' \hat{\chi}' + \frac{\mu_\rho}{2} \hat{\rho}' \hat{\rho}' + \frac{1}{3} \left[ \lambda_{ij} \hat{L}_i \hat{d}_{\beta} + \kappa_{\alpha} \hat{Q}_3 \hat{\chi}' \hat{c}_{\alpha} + \kappa'_{\alpha} \hat{Q}_3 \hat{\chi}' \hat{c}_{\alpha} + \kappa_{2i} \hat{Q}_3 \hat{\chi}' \hat{c}_{i} + \kappa'_{2i} \hat{Q}_3 \hat{\chi}' \hat{c}_{i}
+ \kappa_{3i} \hat{Q}_3 \hat{\chi}' \hat{c}_{i} + \kappa'_{3i} \hat{Q}_3 \hat{\chi}' \hat{c}_{i} + \kappa_{4i} \hat{Q}_3 \hat{\chi}' \hat{c}_{i} + \kappa'_{4i} \hat{Q}_3 \hat{\chi}' \hat{c}_{i} + \kappa_{5i} \hat{Q}_3 \hat{\chi}' \hat{c}_{i} + \kappa'_{5i} \hat{Q}_3 \hat{\chi}' \hat{c}_{i}
+ \kappa_{6i} \hat{Q}_3 \hat{\chi}' \hat{c}_{i} + \kappa'_{6i} \hat{Q}_3 \hat{\chi}' \hat{c}_{i} \right].
\] (2.8)

With this superpotential, we have shown that [16] the boson, Higgs sectors and the fermion one gain masses.

Thus, the \( R \)-parity in this model, as in the SUSY331RN, can be re-expressed via the spin \( S \), new charges \( \mathcal{L} \) and \( \mathcal{B} \) in terms of [15]

\[
R\text{-parity} = (-1)^{2S}(-1)^{3(\mathcal{B}+\mathcal{L})},
\] (2.9)
where the charges $B$ and $L$ for the multiplets are defined as follows [12]

| Triplet   | $L$ | $Q_3$ | $\chi$ | $\rho$ |
|-----------|-----|-------|--------|--------|
| $B$ charge | 0   | $\frac{1}{3}$ | 0      | 0      |
| $\mathcal{L}$ charge | $-\frac{1}{3}$ | $\frac{4}{3}$ | $-\frac{2}{3}$ | $\frac{2}{3}$ |

\begin{equation}
\text{(2.10)}
\end{equation}

| Anti-triplet | $Q_3$ | $\chi'$ | $\rho'$ |
|--------------|-------|--------|--------|
| $B$ charge   | $\frac{1}{3}$ | 0      | 0      |
| $\mathcal{L}$ charge | $-\frac{1}{3}$ | $-\frac{4}{3}$ | $\frac{2}{3}$ |

\begin{equation}
\text{(2.11)}
\end{equation}

| Singlet     | $l^c$ | $u^c$ | $d^c$ | $T^c$ | $D^c$ |
|-------------|-------|-------|-------|-------|-------|
| $B$ charge  | 0     | $-\frac{1}{3}$ | $-\frac{1}{3}$ | $-\frac{1}{3}$ | $\frac{2}{3}$ |
| $\mathcal{L}$ charge | $-1$ | 0      | 0      | 2     | $-2$ |

\begin{equation}
\text{(2.12)}
\end{equation}

From the superpotential given in Eq.(2.8), it is easy to see that the charged leptons gain mass through the term

$$-\frac{\lambda_{1ij}}{3} L_i \rho' l^c_j + hc.$$  \hfill{(2.13)}

Their mass matrix, see Eq.(2.2), is given by

$$v' \sqrt{\frac{2}{3}} \lambda_{1ij}.$$ \hfill{(2.14)}

Note that there is only VEV of $\rho'$ given the charged leptons masses.

Unfortunately, as in the MSSM case, due to conservation of the $R$-parity defined in Eq.(2.7), there are no term which gives neutrinos masses. However, looking at the superpotential of this model given in Eq.(2.6), we see that there is a term $\bar{L}_i \bar{L}_j \hat{\rho}$, which generates the following

$$\lambda_{3ij} \left( L_i L_j \rho + L_i \bar{L}_j \tilde{\rho} + \bar{L}_i L_j \tilde{\rho} \right)$$ \hfill{(2.15)}

The first term in (2.15) generates the following neutrino mass matrix

$$\frac{v}{3 \sqrt{2}} \lambda_{3ij}.$$ \hfill{(2.16)}

As shown in Ref. [16], the mass pattern of this sector is $0, 0, m_\nu, m_\nu, m_\nu, m_\nu$. Note that in this case, we have two massless neutrinos. Unfortunately, as in the non-symmetric version, the quantum corrections at one loop level cannot generate the realistic mass spectrum to the neutrinos. To get the realistic neutrino masses, one have to introduce new physics scale or inflaton with mass around the GUT scale [18].

In this article, we will explore a new mass mechanism to generate neutrino masses at tree level for all neutrinos and study the flavor violating processes, such as neutrinoless double beta decay, which do not exist in our previous work.
3 The discrete symmetry for proton stability and neutrino masses in SUSYECO331

In this section to get neutrino mass and impose flavor violating processes, we chose the new $R$ charge as follows

\[ n_L = n_\chi = \frac{1}{2}, \]
\[ n_\chi' = n_u = n_T = -\frac{1}{2}, \]
\[ n_{Q_3} = n_{\rho'} = 1, \quad n_d = n_D = -2, \]
\[ n_\rho = -1, \quad n_{Q_\alpha} = \frac{3}{2}, \quad n_t = -\frac{3}{2}. \] (3.1)

This $R$-charge is different from those presented in Ref. [16]. We will show that in this case, there exist some new phenomena, which are previously not allowed.

The terms under this symmetry are obtained by

\[ W = W_{RC} + \frac{1}{2} \mu_0 i \hat{L}_i \hat{\chi}' + \frac{1}{3} \left( \lambda_2 \epsilon \hat{L}_i \hat{\chi} \hat{\rho} + \lambda_3 \epsilon \hat{L}_i \hat{L}_j \hat{\rho} + \lambda_{\alpha ij} \hat{Q}_\alpha \hat{L}_i \hat{d}^c_{\beta} + \xi_{\alpha ij} \hat{Q}_\alpha \hat{L}_i \hat{D}^c_{\beta} \right), \] (3.2)

where $W_{RC}$ is defined in Eq.(2.8). The superpotential given in (3.2) will not only allow some interesting flavor violating processes but also will simultaneously give the nucleons a stability. As we will show in next section, this superpotential will also generate masses to all neutrinos in the model.

4 Fermion masses

The superpotential (3.2) provides us the mixing between the leptons and higgsinos as

\[ -\frac{\mu_0}{2} L_i \tilde{\chi}' - \frac{\lambda_2}{3} (L_i \tilde{\chi} \tilde{\rho} + \tilde{\rho} L_i \chi) + H.c. \] (4.1)

With the above terms, we get the mass matrices for the neutral and charged fermions. Diagonalizing these matrices we obtain the physical masses for the fermions. Firstly, let us study the neutral fermions masses.

4.1 Masses of the neutral fermions

In the basis $\Psi^0$ of the form

\[ \left( \nu_1 \nu_2 \nu_3 \nu_1^c \nu_2^c \nu_3^c \bar{\chi}_1^{\alpha_0} \bar{\chi}_2^{\alpha_0} \bar{\rho}^0 \bar{\rho}^0 \bar{B} \bar{W}_3 \bar{W}_8 \bar{X} \bar{X}^* \right), \]
the mass Lagrangian can be written as follows

$$-rac{1}{2}(\Psi^0)^T Y^0 \Psi^0 + H.c.$$  \hspace{1cm} (4.2)

Here $Y^0$ is symmetric matrix with the nonzero elements given in Appendix.A, where the mass eigenstates are given by

$$\tilde{\chi}^0_i = N_{ij} \Psi^0_j, \; j = 1, \cdots, 17.$$  \hspace{1cm} (4.3)

The mass matrix of the neutral fermions consists of three parts: (a) The first part $M_\nu$ is the $6 \times 6$ mass matrix of the neutrinos which belongs to the SUSYECO3; (b) The second part $M_N$ is the $11 \times 11$ mass matrix of the neutralinos, which exists only in the presented supersymmetric version, has been analyzed in [19]; (c) The last part $M_{\nu N}$ arises due to mixing among the neutrinos and the neutral higgsinos. Thus, the mass matrix for the neutral fermions is signified as follows

$$Y^0 = \begin{pmatrix} (M_\nu)_{6 \times 6} & (M_{\nu N})_{11 \times 6} \\ (M_{\nu N}^T)_{6 \times 11} & (M_N)_{11 \times 11} \end{pmatrix},$$  \hspace{1cm} (4.4)

where matrices $M_\nu$ and $M_{\nu N}$ are presented in Eq.(A.1) and Eq. (A.3).

Let us keep the mass constraints from astrophysics and cosmology [20] as well as being consistent with all the earlier analysis [21], the parameters in the mass matrix $M_N$ can be chosen as a typical example:

$$\mu_\rho = 600 \text{ GeV}, \; \mu_\chi = 700 \text{ GeV},$$

$$M_3 = M_8 = 300 \text{GeV}, \; M_{45} = 400 \text{ GeV},$$

$$\mu_{01} = \mu_{02} = \mu_{03} = 1 \text{ GeV},$$

$$\lambda_{21} = \lambda_{22} = \lambda_{03} = 1,$$

$$\lambda_{312} = 4 \cdot 10^{-11}, \; \lambda_{313} = 5 \cdot 10^{-11},$$

$$\lambda_{321} = 6 \cdot 10^{-11}, \; \lambda_{323} = 7 \cdot 10^{-11},$$

$$\lambda_{331} = 8 \cdot 10^{-11}, \; \lambda_{332} = 9 \cdot 10^{-11}.$$  \hspace{1cm} (4.5)

Here in this model, the Higgs bosons’ VEVs are fixed as follows

$$v_{\chi_1} = 15 \text{GeV}, \; v_{\chi'_1} = 10 \text{GeV},$$

$$v_\rho = 244.9 \text{ GeV}, \; v_{\rho'} = 13 \text{ GeV},$$

$$v_{\chi_2} = v_{\chi'_2} = 1000 \text{ GeV}.$$  \hspace{1cm} (4.6)

and the value of $g$ is given in Ref. [20].

Using the values given in Eqs.(4.5,4.6), the eigenvalues of fermion mass matrix are obtained as

$$m_{\tilde{\chi}^0_{17}} = -1282, 27 \text{ GeV}, \; m_{\tilde{\chi}^0_{16}} = 1236, 53 \text{ GeV}, \; m_{\tilde{\chi}^0_{15}} = 1041 \text{ GeV}, \; m_{\tilde{\chi}^0_{14}} = -705, 43 \text{ GeV},$$
\[
m_{\tilde{\chi}^0_{13}} = 631.46 \text{ GeV}, \quad m_{\tilde{\chi}^0_{12}} = 620.21 \text{ GeV}, \quad m_{\tilde{\chi}^0_{11}} = 487.49 \text{ GeV}, \quad m_{\tilde{\chi}^0_{10}} = 385.08 \text{ GeV},
\]
\[
m_{\chi_9} = 304.82 \text{ GeV}, \quad m_{\chi_8} = 186.45 \text{ GeV}, \quad m_{\chi_7} = 57.13 \text{ GeV}, \quad m_{\chi_6} = -0.103 \text{ GeV},
\]
\[
m_{\tilde{\chi}^0_{12}} = -0.043 \text{ GeV}, \quad m_{\tilde{\chi}^0_4} = 2.0415 \cdot 10^{-11} \text{ GeV}, \quad m_{\tilde{\chi}^0_3} = 2.0413 \cdot 10^{-11} \text{ GeV},
\]
\[
m_{\tilde{\chi}^0_2} = -2.0412 \cdot 10^{-11} \text{ GeV}, \quad m_{\tilde{\chi}^0_1} = -2.0410 \cdot 10^{-11} \text{ GeV}.
\]

(4.7)

In the Eq. (4.7), there are some negative eigenvalues. In order to obtain the positive mass, the eigenstates need to be redefined by the chiral rotations.

Eq. (4.7) shows that we have two very distinct sector, one contains the light neutral fermions that we will associate with the usual neutrinos in the SM and the other one contains the heavy neutralinos. The lightest neutralino mass equals to 57 GeV and it is consistent with limits on inelastic dark matter from ZEPLIN-III [22].

Using the values given in Eqs. (4.5, 4.6), the eigenvalues of the mass matrix \((M_N)_{6 \times 6}\) are obtained as

\[
m_{\chi^0_1} = m_{\chi^0_2} = 0 \text{ GeV},
\]
\[
m_{\chi^0_4} = m_{\chi^0_5} = m_{\chi^0_6} = 2.125 \cdot 10^{-20} \text{ GeV}.
\]

(4.8)

These values are smaller than that of the new mechanism given in (4.7). On the other hand, the eigenvalues of the matrix \((M_N)_{11 \times 11}\) are obtained by putting the numerical given in Eqs. (4.5, 4.6) as follows

\[
m_{\chi^0_7} = 1207 \text{ GeV}, \quad m_{\chi^0_8} = 1143 \text{ GeV}, \quad m_{\chi^0_9} = 1040 \text{ GeV}, \quad m_{\chi^0_{10}} = 704.61 \text{ GeV},
\]
\[
m_{\chi^0_{11}} = 585.49 \text{ GeV}, \quad m_{\chi^0_{12}} = 499.85 \text{ GeV}, \quad m_{\chi^0_{13}} = 429.68 \text{ GeV}, \quad m_{\chi^0_{14}} = 374.72 \text{ GeV},
\]
\[
m_{\chi^0_{15}} = 304.81 \text{ GeV}, \quad m_{\chi^0_{16}} = 175.89 \text{ GeV}, \quad m_{\chi^0_{17}} = 56.88 \text{ GeV}.
\]

(4.9)

These results can be understood as follows: Because of the interference matrix \((M_{\nu N})_{6 \times 11}\) between the neutrino mass matrix and the neutralino mass matrix, all neutrinos gain mass at the tree level. This change of the neutrino mass spectrum is suitable to experiment data. Thus the neutrino mass spectrum in the model under consideration depends on the choice of \(R\)-parity. Now we deal with the charged fermions.

### 4.2 Masses of the charged fermions

To write mass matrix of the charged fermions, we will choose the following bases

\[
\psi^- = \left( l_1 \quad l_2 \quad l_3 \quad \bar{W}^- \quad \bar{\nu}^- \quad \bar{\nu}_1^- \quad \bar{\nu}_2^- \quad \bar{\chi}^- \right)^T,
\]
\[
\psi^+ = \left( l_1^c \quad l_2^c \quad l_3^c \quad \bar{W}^+ \quad \bar{\nu}^+ \quad \bar{\nu}_1^+ \quad \bar{\nu}_2^+ \quad \bar{\chi}^+ \right)^T,
\]

(4.10)

and define

\[
\Psi^\pm = \left( \psi^+ \quad \psi^- \right)^T.
\]

(4.11)
With these definitions, the mass term is written in the form

$$-\frac{1}{2}(\Psi^\pm)^T Y^\pm \Psi^\pm + H.c.,$$  \hspace{1cm} (4.12)

where

$$Y^\pm = \begin{pmatrix} 0 & X^T \\ X & 0 \end{pmatrix}. \hspace{1cm} (4.13)$$

Here the $X$ matrix is given by

$$X = \begin{pmatrix}
\frac{\lambda_{11}}{3\sqrt{2}} u' & \frac{\lambda_{12}}{3\sqrt{2}} u' & \frac{\lambda_{13}}{3\sqrt{2}} u' & 0 & 0 & 0 & 0 & 0 \\
\frac{\lambda_{21}}{3\sqrt{2}} w & \frac{\lambda_{22}}{3\sqrt{2}} w & \frac{\lambda_{23}}{3\sqrt{2}} w & \frac{g'v}{\sqrt{2}} & 0 & \mu & 0 & 0 \\
\frac{\lambda_{31}}{3\sqrt{2}} t & \frac{\lambda_{32}}{3\sqrt{2}} t & \frac{\lambda_{33}}{3\sqrt{2}} t & \frac{gw}{\sqrt{2}} & 0 & \mu & 0 & 0 \\
\frac{\mu_0}{3\sqrt{2}} & \frac{\mu_0}{3\sqrt{2}} & \frac{\mu_0}{3\sqrt{2}} & \frac{gw}{\sqrt{2}} & 0 & 0 & \mu_X & 0
\end{pmatrix}.$$

The chargino mass matrix $Y^\pm$ is diagonalized by using two unitary matrices, $D$ and $E$, defined by

$$\tilde{\chi}_i^+ = D_{ij} \Psi_j^+, \quad \tilde{\chi}_i^- = E_{ij} \Psi_j^-, \quad i, j = 1, \ldots, 8. \hspace{1cm} (4.14)$$

The characteristic equation for the matrix $Y^\pm$ is

$$\text{det}(Y^\pm - \lambda I) = \text{det} \left[ \begin{pmatrix} -\lambda & X^T \\ X & -\lambda \end{pmatrix} \right] = \text{det}(\lambda^2 - X^T \cdot X). \hspace{1cm} (4.15)$$

Since $X^T \cdot X$ is a symmetric matrix, $\lambda^2$ must be real and positive because $Y^\pm$ is also symmetric. In order to obtain eigenvalues, one only have to calculate $X^T \cdot X$. The diagonal mass matrix can be written as

$$M_{SCM} = E^* XD^{-1}. \hspace{1cm} (4.16)$$

To determine $E$ and $D$, it is useful the following observation

$$M_{SCM}^2 = DX^T \cdot XD^{-1} = E^* X \cdot X^T (E^*)^{-1}. \hspace{1cm} (4.17)$$

It means that $D$ diagonalizes $X^T \cdot X$, while $E^*$ diagonalizes $X \cdot X^T$. In this case we can define the following Dirac spinors:

$$\Psi(\tilde{\chi}_i^+) = \begin{pmatrix} \tilde{\chi}_i^+ \\ \tilde{\chi}_i^- \end{pmatrix}^T, \quad \Psi^c(\tilde{\chi}_i^-) = \begin{pmatrix} \tilde{\chi}_i^- \\ \tilde{\chi}_i^+ \end{pmatrix}^T. \hspace{1cm} (4.18)$$

where $\tilde{\chi}_i^+$ is the particle and $\tilde{\chi}_i^-$ is the anti-particle [23].

9
Using the values given in Eqs.(4.5,4.6), the eigenvalues of the charged fermion matrix given at Eq.(4.14) are obtained as

\[
\begin{align*}
    m_e & = \ 5 \times 10^{-4} \text{ GeV}, \ m_\mu = 0, 104 \text{ GeV}, \ m_\tau = 1, 179 \text{ GeV}, \\
    m_{\tilde{\chi}^\pm_1} & = 76, 09 \text{ GeV}, \ m_{\tilde{\chi}^\pm_2} = 522, 92 \text{ GeV}, \\
    m_{\tilde{\chi}^\pm_3} & = 600, 22 \text{ GeV}, \ m_{\tilde{\chi}^\pm_4} = 1168 \text{ GeV}.
\end{align*}
\] (4.19)

It is easily to see that the mass matrix is divided in two sectors: one heavy which is identified as the charginos and has been studied in our previous work [16]. Another one light which is identified as the usual leptons.

On the other hand, if we take the mass matrix from our work and using the same values to the parameters we get masses of the charged leptons:

\[
\begin{align*}
    m_e & = \ 5 \times 10^{-4} \text{ GeV}, \ m_\mu = 0, 119 \text{ GeV}, \ m_\tau = 1, 249 \text{ GeV}.
\end{align*}
\] (4.20)

Now using the mass matrix to the charginos given in [19] we get

\[
\begin{align*}
    m_{\tilde{\chi}^+_1} & = 69, 05 \text{ GeV}, \ m_{\tilde{\chi}^+_2} = 522, 78 \text{ GeV}, \ m_{\tilde{\chi}^+_3} = 600, 01 \text{ GeV}, \\
    m_{\tilde{\chi}^+_4} & = 600, 42 \text{ GeV}, \ m_{\tilde{\chi}^+_5} = 1168 \text{ GeV}.
\end{align*}
\] (4.21)

In this case, the new elements put down masses of the muon and tauon and at the same time remove the mass degeneracy between \( \chi_3 \) and \( \chi_4 \). Anyway we can see that the mass matrix in the charged fermion sector is basically divided in two sectors: one giving masses of the usual known leptons and another one giving masses of the new charginos.

5 Nucleon decay in the SUSYECO331

Let us remind that in the MSSM [24, 25, 26, 27, 17], the \( R \)-parity violating terms in superpotential are given by \( W_{2RV} + W_{3RV} + \overline{W}_{2RV} + \overline{W}_{3RV} \), where

\[
\begin{align*}
    W_{2RV} & = \ \mu_0 a \epsilon \hat{L}_a \hat{H}_2, \\
    W_{3RV} & = \ \lambda_{abc} \epsilon \hat{L}_a \hat{H}_b \hat{c}_c + \lambda'_{iaj} \epsilon \tilde{Q}_i \hat{L}_a \hat{d}_j + \lambda''_{ijk} \epsilon \tilde{d}_i \hat{u}_j \hat{d}_k.
\end{align*}
\] (5.1)

Here we have suppressed \( SU(2) \) indices, \( \epsilon \) is the antisymmetric \( SU(2) \) tensor. Above, and below in the following, the subindices \( a, b, c \) run over the lepton generations \( e, \mu, \tau \) but a superscript \( c \) indicates charge conjugation; \( i, j, k = 1, 2, 3 \) denote quark generations.

Note that the \( \lambda' \)-coupling in the MSSM is similar to the \( \xi_7 \)-coupling in the most general form of the superpotential in the SUSYECO331, which is given in Eq.(2.6), and the coupling \( \lambda'' \) is similar to the coupling \( \xi_3 \).

From Eq. (5.1), we can obtain the \( B \)-violating Yukawa couplings as follows

\[
\lambda''_{ijk} \bar{d}_{iR} u_{jL} \tilde{d}_{k} + H.c.
\] (5.2)
The interactions among lepton, quark and squark are given by
\[ \lambda_{\alpha j} \left( \bar{d}_{R}^c \nu_{aL} - \bar{u}_{iR}^c \nu_{aL} \right) \bar{d}_{j} + H.c. \] (5.3)

Taking into account Eqs. (5.2,5.3), we can draw two Feynmann diagrams describing the proton decay, which are shown in the Fig.1 and Fig.2. The Fig.1 describes the proton decay into charged leptons. At the lowest approximation, there is no mixing in the quark, neutrino and squark sectors. It means that \( u_1 \equiv u, u_2 \equiv c \) and \( u_3 \equiv t \) and so on. The proton could decay into \( p \to \pi^0 e^+ \), \( p \to \bar{D}^0 \mu^+ \) and \( p \to (u_1 t^c) \tau^+ \), but the last two modes are forbidden kinematically.

Figure 1: Proton decay into charged leptons in the MSSM and in SUSYECO331 (with \( \lambda'' \to \xi_3 \) and \( \lambda' \to \xi_7 \)).

The analysis presented above shows that the proton can decay only in \( p \to \pi^0 e^+ \). On dimensional grounds, we estimate
\[ \Gamma(p \to \pi^0 e^+) \approx \frac{\alpha(\lambda') \alpha(\lambda'')}{m_{\tilde{d}_k}^2} M_{\text{proton}}^5, \] (5.4)

where \( \alpha(\lambda) = \lambda^2/(4\pi) \). Giving \( \tau(p \to e\pi) > 1.6 \times 10^{33} \) years [20] and taking \( m_{\tilde{d}_k} \sim \mathcal{O}(1\text{TeV}) \), we obtain
\[ \lambda'_{11k} \lambda''_{11k} < 5.29 \times 10^{-26}. \] (5.5)

It is consistent with the limits presented in [28]. For a more detailed calculation see [29, 30]. Other decay modes, where the proton decay into antineutrino, have been considered in [31]. The mentioned decay modes are \( p \to \pi^+ \bar{\nu}_e, p \to K^+ \bar{\nu}_\mu, p \to B^+ \bar{\nu}_\tau \). In these cases, we get the same numerical results as presented in Eq.(5.5).

\(^1\text{Again, we are bare mixing in the quarks, neutrinos and squarks sectors}\)
Figure 2: Proton decay into antineutrinos in the MSSM and in SUSYECO331 (with $\lambda'' \rightarrow \xi_3$ and $\lambda' \rightarrow \xi_7$).

The bound presented in Eq.(5.5) is so strict. So the natural explanation only is that at least one of the couplings has to be zero. In order to avoid that the simplest way is to impose the $R$-symmetry. This leads to avoid the proton decay.

In our superpotential given at Eq.(3.2), we allow only interactions that violate $L$-number. Therefore the proton is stable at tree-level. However it is not only forbidden the dangerous processes of proton decay but also forbidden the neutron-antineutron oscillation. This oscillation was studied in detail in [32, 33, 34, 35].

In [14, 15], in the framework of the supersymmetric 3-3-1 model with right handed neutrinos, the $R$-parity violating interaction was applied for instability of the nucleon. The result is consistent with that of the present article (noting that in Ref [14], the authors have taken a lower limit of the proton lifetime equal to $10^{32}$ years).

6 Neutrinoless double beta decay in SUSYECO331

Neutrinoless double beta ($0\nu\beta\beta$) decay is a sensitive probe of physics beyond the standard model, see Fig.(3), since it violates the conservation of lepton number [36, 37, 38, 39]. Such experimental results if available will cast stringent constraints on new physics. The nucleon level process of $0\nu\beta\beta$ decay, $n+n \rightarrow p+p+e^-+e^-$, can be obtained via the lepton number violating subprocess, $d+d \rightarrow u+u+e+e$. For experiments, the parent nucleus $A_Z$ can decay to a daughter nucleus $A_{Z+2}$ via the two steps of virtual transitions, $A_Z \rightarrow A_{Z+1} + \beta^- \rightarrow A_{Z+2} + \beta^- + \beta^-$. It is to be noted that only the ordinary double beta reactions have been experimentally observed, while the active searches for the $0\nu\beta\beta$ reactions are actually get with null results. The experimental measurements of $0\nu\beta\beta$ decay are currently accounted for even-even heavy nuclei such as $^{48}Ca \rightarrow ^{48}Ti$, $^{76}Ge \rightarrow$
Figure 3: Neutrinoless double beta decay in SM with massive neutrinos.

$^{76}Se, \, ^{82}Se \rightarrow ^{82}Kr, \, ^{100}Mo \rightarrow ^{100}Ru, \, ^{128}Te \rightarrow ^{128}Xe$. The most stringent bounds have been given by the Moscow-Heidelberg collaboration [37, 38] on the $0\nu\beta\beta$ decay half-life of $^{76}Ge$ as $T_{\nu\nu} > [1.1 \times 10^{25}, \, 1.5 \times 10^{25}]$ yr, respectively. We can find in Ref. [40] for a general review, and Ref. [39] for a summary of the experimental results as well as the future projects.

Particularly, for the conventional $0\nu\beta\beta$-decay with massive Majorana neutrino exchange it implies an upper bound on the neutrino mass below 1 eV. The supersymmetric mechanism of $0\nu\beta\beta$ decay was first suggested by Mohapatra [41] and further studied in Refs. [42, 43]. In Ref. [44], the $R$ parity violating Yukawa coupling of the first generation is strongly bounded by $\lambda'_{111} \leq 3.9 \times 10^{-4}$ due to the gluino exchange $0\nu\beta\beta$-decay. Babu and Mohapatra [45] have latter implemented another contribution comparable with that via the gluino exchange. This set stringent bounds on the products of $R$ parity violating Yukawa couplings $\lambda'_{11i} \lambda'_{1i1}$ of $i$th generation index, see Fig.(4). The constraints on $\lambda'_{111}$ coming from the $0\nu\beta\beta$ half-life limit have been calculated [46, 47]

$$\lambda'_{111} \leq 3.9 \times 10^{-4} \left( \frac{m_{\tilde{q}}}{100 \text{ GeV}} \right)^{2} \left( \frac{m_{\tilde{g}}}{100 \text{ GeV}} \right)^{1/2}$$ (6.1)

with the assumption $m_{\tilde{d}_{R}} \simeq m_{\tilde{u}_{L}}$ and $m_{\tilde{q}}, \, m_{\tilde{g}}$ being squark and gluino masses, respectively.

We find further [46]

$$\lambda'_{113} \lambda'_{311} \leq 1.1 \times 10^{-7},$$ (6.2)

$$\lambda'_{112} \lambda'_{121} \leq 3.2 \times 10^{-6}.$$ (6.3)

The analyses presented in the MSSM to the $0\nu\beta\beta$-decay are still hold in the SUSYECO331 model, because the $\lambda'$ is allowed in our superpotential as shown at Eq.(3.2).
Figure 4: Neutrinoless double beta ($0\nu\beta\beta$) decay in the MSSM with massive neutrinos and in SUSYECO331 (with $\lambda' \rightarrow \xi\gamma$).

7 Conclusion

In this paper we have presented new $R$-symmetry for the supersymmetric economical $SU(3)_C \otimes SU(3)_L \otimes U(1)_X$ mode and studied neutrino mass by implication for the obtained $R$-parity. The neutrino mass spectrum is affected by the chosen $R$-parity. By imposing the $R$-parity, namely: $R$-parity $= (-1)^{2S}(-1)^{3(B+L)}$, the neutrino mass spectrum at the tree level contains two massless.

We remind that in the non-supersymmetric economical 3-3-1 model, to give neutrinos a correct mass pattern, we have to introduce new mass scale around the GUT scale. The same situation happens in the supersymmetric version and the above puzzle can be solved with the help of the inflaton having mass in the range of the GUT scale. In this paper, we have showed that by the chosen $R$ parity and the set of parameters, the pseudo-Dirac neutrino mass is available.

We have found that the other $R$-parity given in (3.1) leads to the interference between the neutrino and neutralino mass matrices. Because of this interference mass matrix, all neutrino gain mass only just at the tree level and the interference mass matrix does not much affect on the neutralino mass spectrum. In the charged lepton sector, with the new $R$ parity, there is also an interference mass matrix between the usual leptons and charginos. By taking the numerical, we show that the charged sector is basically divided in two distinct sectors: one giving the usual known leptons and the other ones given the new charginos. If we ignore the interference charged lepton mass matrix, the chargino mass spectrum is
degenerated. This degenerated mass spectrum is removed by imposing the new R-parity.

The new $R$-parity not only provides a simple mechanism for the mass generation of the neutrinos but also gives some lepton flavor violating interactions at the tree level. This will play some important phenomenology in our model such as the proton’s stability, forbiddance of the neutron-antineutron oscillation and neutrinoless double beta decay.

A Elements of neutrino mass matrix in SUSYECO331

The elements of $Y^0$ presented in Eq. (4.2) is given by Eq.(4.4) where

$$M_{\nu} = \begin{pmatrix}
0 & 0 & 0 & 0 & G_{12} & G_{13} \\
0 & 0 & 0 & G_{21} & 0 & G_{23} \\
0 & 0 & 0 & G_{31} & G_{32} & 0 \\
0 & G_{21} & G_{31} & 0 & 0 & 0 \\
G_{12} & 0 & G_{32} & 0 & 0 & 0 \\
G_{13} & G_{23} & 0 & 0 & 0 & 0
\end{pmatrix}$$

(A.1)

and

$$G_{ab} = \frac{v}{3\sqrt{2}} \left( \lambda_{3ab} - \lambda_{3ba} \right),$$

(A.2)

while

$$M_{\nu N} = \begin{pmatrix}
0 & \frac{\mu_{01}}{2} & 0 & \frac{\lambda_{31}}{\sqrt{2}} v & \frac{\lambda_{31}}{\sqrt{2}} w & 0 & 0 & 0 & 0 & 0 \\
0 & \frac{\mu_{02}}{2} & 0 & \frac{\lambda_{32}}{\sqrt{2}} v & \frac{\lambda_{32}}{\sqrt{2}} w & 0 & 0 & 0 & 0 & 0 \\
0 & \frac{\mu_{03}}{2} & 0 & \frac{\lambda_{33}}{\sqrt{2}} v & \frac{\lambda_{33}}{\sqrt{2}} w & 0 & 0 & 0 & 0 & 0 \\
0 & -\frac{\lambda_{31}}{\sqrt{2}} v & 0 & \frac{\mu_{01}}{2} & -\frac{\lambda_{31}}{\sqrt{2}} w & 0 & 0 & 0 & 0 & 0 \\
0 & -\frac{\lambda_{32}}{\sqrt{2}} v & 0 & \frac{\mu_{02}}{2} & -\frac{\lambda_{32}}{\sqrt{2}} w & 0 & 0 & 0 & 0 & 0 \\
0 & -\frac{\lambda_{33}}{\sqrt{2}} v & 0 & \frac{\mu_{03}}{2} & -\frac{\lambda_{33}}{\sqrt{2}} w & 0 & 0 & 0 & 0 & 0
\end{pmatrix}$$

(A.3)

and $M_N$ is presented in [19].
