INTRODUCTION

Gout is a relatively common, crystal deposition disease in which monosodium urate crystals are deposited in joint and periarticular tissues of the extremities. Involvement of the spine is exceedingly rare. Most patients with spinal gout present with symptomatic spinal cord compression. Diffuse involvement of tophi deposition inside the spinal central canal has not been reported. We now present a case of chronic tophaceous gout with extensive spinal involvement that resulted in diffuse spinal cord compression and led to paraplegia.

CASE REPORT

A 52-year-old man presented with a history of progressive motor weakness and sensory loss of both upper and lower extremities over the last two years ago. His status had been deteriorating more rapidly over the previous one year and he was bed-bound on admission. The patient had a past medical history of diabetes mellitus for 22 years and diabetic nephropathy for 12 years. He also had hypertension for over 10 years and was in a state of chronic renal failure. He was suffering from arthralgia of multiple sites in both hands, wrists, knees, shoulders and paresthesia below shoulders. On a neurologic examination, muscle power of all limbs was reduced to grade I.

In conventional radiographs of the lumbosacral spine taken on the second day of admission, we noticed focal sclerotic changes at the anterior corner of the superior endplate of the 4th lumbar vertebrae (Fig. 1A). However, after magnetic resonance imaging, we recognized a high density area at the posterior aspect of the vertebral bodies. Other conventional radiographs of both hands and feet revealed radio-opaque, mass-like depositions in soft tissues and marginal bony erosions in multiple sites (Fig.
The uric acid level in the blood was 12.2 mg/dL. In an aspirate of the knee joint, monosodium urate crystals were found on monopolarized microscopes. Chronic tophaceous gout was suspected, and an MRI examination of the spine was done to evaluate for motor weakness of the extremities. Sagittal T2-weighted images of the whole spine revealed a long band-like lesion just posterior to the vertebral bodies that showed low signal intensity with heterogeneity (Fig. 2). The band was located in the anterior epidural space and was continuous from the 2nd cervical vertebrae to the 5th lumbar vertebrae. A small erosion was noted at the lower anterior corner of the 6th thoracic vertebral body. The lesion showed low to intermediate signal on T1-weighted images and no enhancement (Fig. 3). The spinal cord was compressed in the long segment from the level of the 3rd cervical vertebrae to the 8th thoracic vertebral body without a clearly notable signal change. Costovertebral joints were involved, with erosion of adjacent vertebrae. The lesion was seen as hyperdense soft tissue, less dense than bone or calcification on an unenhanced CT scan (Fig. 4). The atlantodental joint and the facet joint area were also involved, showing soft tissue deposition in synovial space similar to deposition in epidural space (Fig. 5). Findings were consistent with a diagnosis of

Fig. 1. Conventional radiographs of a 52-year-old man with paraplegia and arthralgia. A. On a lateral view of the lumbar spine, a hyperdense line is noted in the anterior portion of the central canal (arrows). B. A foot AP view shows multiple radioopaque depositions in soft tissue (arrowheads) and marginal bony erosions in the 1st metatarsophalangeal, tarsometatarsal, talonavicular and calcaneocuboidal joints (arrows). Subluxation of the 2nd-5th metatarsal joints is seen. C. A apicoposterior view of wrist shows radioopaque tophi (arrowheads).

Fig. 2. A sagittal T2-weighted image of the whole spine demonstrating a long heterogeneous low signal band of tophi deposited in the anterior epidural space (arrows). A focal erosion is noted at the anterior margin of the T6 body (arrowhead). The spinal cord was compressed from C3 to T8.
The prevalence of gout is much higher in men than in women and rises with age. Gout frequently presents in the peripheral joints, such as the first metatarsophalangeal joint, the knee, the ankle and maybe even the distal interphalangeal joint, but this is not always the case (1, 2). Tophi deposition can happen anywhere in the body including unusual locations such as the proximal appendicular or axial skeleton (1, 5).

Axial gouty arthropathy can clinically mimic spinal metastases, spinal stenosis, or infection (2). Clinical manifestations of spinal gout are nonspecific, with local pain, radicular symp-

The patient is undergoing conservative management because of the high surgical risks which were based on the patient’s status and the low possibility of recovery from neurologic symptoms.

**DISCUSSION**

Gout is a common metabolic disorder caused by deposition of monosodium urate crystals within or around the joints after chronic hyperuricaemia. It affects 1-2% of adults in developed countries. The prevalence of gout is much higher in men than in women and rises with age. Gout frequently presents in the peripheral joints, such as the first metatarsophalangeal joint, the knee, the ankle and maybe even the distal interphalangeal joint, but this is not always the case (1, 2). In conclusion, spinal gout is rare, but it is important to be aware of the possibility. Although biopsy is required for the definitive diagnosis, it is not always necessary if clinical and MR findings provide a reasonably high suspicion for gout. The diagnosis of spinal gout should be considered when the MRI demonstrates intermediate or low signal on T1 weighted images and deposits with low signal foci on all sequences, especially those involving the posterior elements.

결절성 통풍의 광범위한 척추침범: 드문 증례 보고

신민우 · 이지혜 · 조우호 · 김재형 · 정명자 · 김성희 · 김지영 · 김수현 · 강미진 · 조현선 · 이한비

통풍은 상대적으로 흔한 결정 침착성 질환으로 요산알나트륨결정은 대개 말단 관절과 관절 주위 조직에 침착하게 되며, 척추에 침착하는 경우는 매우 드물다. 척추 통풍이 있는 환자들은 대부분 척수 압박으로 인한 증상을 보이며, 결정 침착이 척추강 내 전반에 분포하여 척수를 압박하는 경우는 이전에 보고된 적이 없다. 이에 저자들은 광범위하게 척추강을 침범하여 척수 압박을 일으킨 만성 결절성 통풍 환자의 증례를 보고하고자 한다.
