Gaucher disease is a lysosomal storage disease for which enzyme replacement therapy has proven to be effective. A switch-over clinical trial was performed to evaluate the efficacy and safety of Abcertin® (ISU Abxis, Seoul, Korea) in subjects with type 1 Gaucher disease who were previously treated with imiglucerase. Five Korean patients with type 1 Gaucher disease were enrolled. Previous doses of imiglucerase ranged from 30 to 55 U/kg every other week. The same dose of Abcertin® was administered to all patients for 24 weeks. Primary efficacy endpoints were changes in hemoglobin levels and platelet counts, and the secondary efficacy endpoints included changes in liver and spleen volumes, serum biomarkers, skeletal status and bone mineral density (BMD). During the study period, no statistically significant changes were observed in all parameters including hemoglobin levels and platelet counts, liver and spleen volumes, skeletal status and BMD. Abcertin® administration was continued in three patients for another 24 weeks as an extension of the study. Hemoglobin levels and platelet counts were maintained in all three patients. In conclusion, the efficacy and safety of Abcertin® are similar to those of imiglucerase, and Abcertin® is an effective therapeutic agent for patients with type 1 Gaucher disease (Clinical Trial Registry No. NCT02053896 at www.clinicaltrials.gov).

INTRODUCTION

Gaucher disease (OMIM #230800) is an autosomal recessive disease caused by a β-glucocerebrosidase deficiency, and characterized by hepatosplenomegaly, anemia, thrombocytopenia, bone pain, and growth retardation (1). β-glucocerebrosidase degrades glucocerebroside into glucose and ceramide, and loss of function leads to accumulation of glucocerebrosides in various tissues including the liver, spleen, central nervous system, skeletal system, and lungs (2). Gaucher disease can be categorized into three subtypes according to the presence of neurological deterioration, age at diagnosis, and rate of progression, namely, non-neuronopathic (type 1), acute neuronopathic (type 2), and chronic neuronopathic types (type 3) (3). Type 1 Gaucher disease is the most prevalent form and is characterized by an absence of neurologic symptoms.

Enzyme replacement therapy (ERT) remarkably improves the clinical outcome of patients with Gaucher disease, particularly hepatosplenomegaly and hematological abnormalities (4). Aglucerase (Ceredase®, Genzyme Corp., Cambridge, MA, USA), a mannose-terminated placental-derived β-glucocerebrosidase, was approved by the Food and Drug Administration (FDA) for treatment of type 1 Gaucher disease in 1991 (5). Similarly, imiglucerase (Cerezyme®, Genzyme Corp.), a recombinant human β-glucocerebrosidase, was approved by the FDA in 1994. Imiglucerase can be produced in large quantities in Chinese hamster ovary (CHO) cells via recombinant technology, and used the macrophage mannose receptor to deliver the enzyme to lysosomes (6). Imiglucerase is considered the prototype for ERT in lysosomal storage diseases, and the long-term safety and ef-
ficacy of imiglucerase has been well validated (7). Currently, two other forms of recombinant β-glucocerebrosidase have been developed for treatment of Gaucher disease: velaglucerase alfa (Shire Human Genetic Therapies, Lexington, MA, USA) and taliglucerase alfa (Pfizer, New York, NY, USA) (8, 9). Despite having different oligosaccharide modifications, their therapeutic efficacy is similar (7, 10).

Unfortunately, the high cost and global shortage of imiglucerase has been problematic for patients and health care providers (11, 12). However, a biosimilar of imiglucerase, Abcertin® (ISU302, ISU Abxis, Seoul, Korea), has recently been developed. Therefore, this study was performed to evaluate the short-term efficacy and safety of Abcertin® in patients with type 1 Gaucher disease who were previously treated with imiglucerase.

MATERIALS AND METHODS

Subjects

A total of six patients with non-neuronopathic Gaucher disease were screened for enrollment. All patients were diagnosed with Gaucher disease by a documented deficiency of leukocyte glucocerebrosidase activity, and mutation analysis of the GBA gene using genomic DNA from peripheral blood leukocytes. Polymerase chain reactions of all coding exons and exon-intron boundaries were performed with allele-specific primers, and direct sequencing of amplification products was performed in both the forward and reverse directions using an ABI3130x1 Genetic Analyzer (Applied Biosystems, Foster City, CA, USA).

The inclusion criteria for this study were as follows: 1) patients diagnosed with type 1 Gaucher disease; 2) patients who were stable with Cerezyme® therapy and who were maintained on a dose of Cerezyme® for at least 6 months prior to enrollment; 3) patients older than 2 yr of age; and 4) nonpregnant female patients. All these patients were stable following treatment with imiglucerase. Stable treatment was defined as an absence of neurologic deficits, normal hemoglobin levels, platelet counts greater than 100,000/μL, normal or an absence of deteriorated bone mineral density, and an absence of aggravated splenomegaly or hepatomegaly.

We excluded patients who exhibited fluctuating hemoglobin or platelet levels (at least six months prior to the study), hypersensitivity to imiglucerase (Cerezyme®), anemia due to iron, folic acid, or vitamin B12 deficiency and clinical findings of type 2 or 3 Gaucher disease. Patients who received miglustat, erythrocyte growth factor, or systemic corticosteroids during the six months prior to enrollment were also excluded.

Study drug: Abcertin®

Abcertin® (ISU302, ISU Abxis, Seoul, Korea) is a recombinant protein produced by genetically engineered CHO cells. Abcertin® consists of 497 amino acids with two disulfide bridges and four N-glycosylation sites, together with a terminal mannose exposed by multi-step digestion. Abcertin® has a similar amino acid sequence to human glucocerebrosidase with only a single amino acid difference (arginine replaced with histidine at the 495th amino acid). The imiglucerase was produced in serum-free medium using suspension cell culture technology and was purified a series of chromatography steps. The structural, physicochemical, immunological and biological properties of imiglucerase have been well characterized both in vivo and in vitro.

Study design

The study was an open-label, switch-over study from Cerezyme® to Abcertin® (ISU302). Abcertin® was administered to each subject at a dose of 30-60 U/kg every two weeks. Abcertin® (30-60 U/kg) was diluted with 0.9% saline solution for injection at a final volume of 100-200 mL. At the first visit, the study drug was administrated intravenously at a rate of ≤ 1 U/kg/min for approximately 90 ± 3 min for pharmacokinetic assessments. At the second or later visits, the study drug was administered for 60 min or longer. For three subjects, the study period was extended for another 6 months because of a supply shortage of Cerezyme®. The 6-month extension was approved by the Korea FDA.

Pharmacokinetic assessment

Pharmacokinetic assessments were performed during the first infusion. Blood samples were collected at nine time points (before infusion, and at 15, 30, 60, 90, 100, 120, 150, and 180 min), and β-glucocerebrosidase activity was measured. Blood concentration time courses are shown as a linear or log/linear graph for each subject. Cmax and Tmax were measured and the area under the curve (AUC) was calculated using a linear up/log down method. Parameters were calculated using Phoenix WinNonlin Version 6.2 (Pharsight, CA, USA) software and standard non-compartmental methods.

Subject group for efficacy and safety analysis

Subjects were classified into three groups, as follows: 1) a modified intention-to-treat (MITT) group consisting of subjects who underwent primary efficacy assessment one or more times after drug administration; 2) a per-protocol (PP) group consisting of subjects included in the MITT who did not violate the inclusion/exclusion criteria and who were administered the study drug for at least 60% of the total 48 weeks. Subjects who completed less than 60% of the study or withdrew were excluded from the PP group; and 3) an intention-to-treat (ITT) group consisting of all subjects who received the study drug.

Assessment of efficacy

Primary efficacy endpoints were hemoglobin concentration and platelet counts before and during the study period. Sec-

Fig. 1. Mean change in hemoglobin levels (A), platelet count (B), angiotensin converting enzyme (C), acid phosphatase (D), chitotriosidase (E), and bone mineral density (BMD) of L-spine (F) and femur neck (G) in Abcertin® treated patients. The phase 2 clinical trial included five patients for 24th weeks. The study was extended by another 24 weeks for three subjects. Data are expressed as mean ± standard deviation.
voluntary withdrawal from participation. All five patients were included in the ITT group for safety assessment, and the MITT and PP groups for efficacy assessment.

**Pharmacokinetics of Abcertin**
Pharmacokinetic profiles were assessed after Abcertin was intravenously administered for 90 min. Abcertin had a Tmax of 1.34 ± 0.32 hr (range, 1.00-1.67 hr), and clearance half-time of 0.11 ± 0.01 hr (range, 0.09-0.12 hr). In particular, the Cmax and AUC increased in proportion to the dose, but no dose proportionality was observed.

**Efficacy of Abcertin**
The mean hemoglobin concentration was 13.76 ± 1.89 g/dL (range, 12.30-16.20 g/dL) at baseline, and increased to 13.86 ± 2.61 g/dL after 24 weeks of treatment. The mean platelet count was 154.4 ± 34.62 × 10^11/μL (range, 113-209 × 10^11/μL) at baseline and increased to 162.60 ± 47.04 × 10^11/μL after 24 weeks of treatment. However, both of these changes were not statistically significant (Table 2, Fig. 1).

The mean ACE level increased from 79.42 ± 31.77 U/L at baseline to 81.50 ± 45.84 U/L after 24 weeks of drug administration. The mean acid phosphatase level decreased from 18.68 ± 8.71 IU/L at baseline to 17.10 ± 4.77 IU/L after 24 weeks. The mean chitotriosidase level decreased from 1,279.82 ± 1,041.47 nM/mL/hr at baseline to 1,103.76 ± 884.36 nM/mL/hr after 24 weeks. The mean liver volume decreased from 1.03 ± 0.19 MN at baseline to 0.93 ± 0.09 MN after 24 weeks. The mean spleen volume increased from 3.47 ± 1.21 MN at baseline to 3.61 ± 1.65 MN after 24 weeks of drug administration. However, none of these changes were statistically significant.

No changes in osteosclerosis were observed because the osteosclerosis score was 0 (none) at the baseline and 0 (none) after 24 weeks of drug administration. For osteonecrosis, one subject improved from a score of one point (mild) to zero points (none). The mean score changed from 0.20 ± 0.45 points at baseline to 0.00 ± 0.00 points after 24 weeks of drug administration. The mean lumbar spine Z-score increased from -1.27 ± 0.40 at baseline to -0.80 ± 0.53 after 24 weeks of drug administration. The mean femur neck Z-score increased from -0.43 ± 1.37 at baseline to -0.20 ± 1.35 at 24 weeks. However, no statistically significant differences were observed for all of these second efficacy endpoints (Table 2).

**Safety**
No significant changes in systolic/diastolic blood pressure, heart rate, and body temperature were found during the study period. Adverse events occurred in all five subjects, as follows: three cases of nasopharyngitis and one case of acute tonsillitis; two cases of arthralgia; one case of diarrhea and one case of abdominal pain; one case of cough; and one case of vaginal discharge. There were no serious adverse events associated with administration of the study drug. In addition, no adverse events were potentially life threatening or required withdrawal from the study. No patients generated antibodies against Abcertin after drug administration.

**DISCUSSION**
This study was a phase 2 multi-center, open-label, switch-over trial to assess the safety and efficacy of Abcertin in patients with type 1 Gaucher disease previously treated with Cerezyme®. Abcertin was effective and well tolerated in patients with type 1 Gaucher disease. Hemoglobin concentrations and platelet counts, liver and spleen volumes, skeletal status, and BMD were maintained, and no clinically significant adverse events occurred in all patients.

The introduction of ERT has significantly impacted the treatment of type 1 Gaucher disease. At present, available enzyme therapies include imiglucerase, velaglucerase alfa, and taliglucerase alfa, all of which are generally administered intravenously every other week (6, 8, 17). Unlike imiglucerase, velaglucerase alfa has the same amino acid sequence as native human glucocerebrosidase and is produced by proprietary gene activation technology in HT-1080 human fibroblast cells (18). It is a monomeric glycoprotein (~63 kDa, containing 5 potential N-linked glycosylation sites) that targets macrophages via mannose receptors, and acts to degrade accumulated glucocerebrosides within the macrophages (19). The safety and efficacy of velaglucerase alfa were previously demonstrated in a phase 1/2, open-label study in adult patients with type 1 Gaucher disease and approved by the FDA in 2010 (9). Taliglucerase alfa is a recombinant human β-glucocerebrosidase produced by carrot plant root cells, which was approved by the FDA in 2012 as a novel ERT for patients with Gaucher disease (8).

The relatively few therapeutic options and high cost of ERT represent an inherent problem for the treatment of patients with type 1 Gaucher disease (9). Global dependence on a single product, Cerezyme®, is problematic, particularly with the recent shortage of this product (20). Although velaglucerase alpha and taliglucerase alpha was approved for the long-term treatment of Gaucher disease in > 40 countries, including the Unites States, European Union member states, and Israel (21), Cerezyme® still has been used worldwide. The commercially available substrate reduction agent, miglustat (Zavesca®, Actelion, Pharmaceuticals Ltd), was also used during the global shortage despite the caveat of its restricted indication to patients who are unwilling or unable to receive IV ERT (22). However, ERT is generally more effective and safer than other therapeutic options.

Therefore, a new biosimilar to imuglucerase, Abcertin®, was recently developed to potentially reduce medical costs, particularly in underprivileged countries, and to ease supply shortages.
of Cerezyme®. The host cell used in Abcertin® production is a mutant strain of CHO cells with an inactivated dihydrofolate reductase gene. For the development of the recombinant cell line producing Abcertin® (ISU302), host cells were transfected with an expression vector, followed by gene amplification, subcloning, and suspension culture to obtain a cell line that produces Abcertin® with a high yield. Notably, the structural, physicochemical, and biological characteristics of the Abcertin® are comparable to Cerezyme®. Phase 1 study for Abcertin® was performed to determine the safety and tolerability and pharmacokinetics in 8 healthy subjects, including placebo for 2 subjects. As a result, there were no serious adverse events and clinically significant change in vital signs, local tolerability tests, and laboratory tests (unpublished data).

During the study period, all patients maintained normal hemoglobin levels and platelet counts > 100,000/μL, and all patients maintained near normal liver and spleen volumes. The findings reported herein demonstrate that adverse events associated with Abcertin® were generally mild in severity and were mostly unrelated to the therapy. No patients enrolled in this study developed antibodies against Abcertin®, and no serious adverse events were observed regardless of administration setting or duration of exposure. Furthermore, and no patients withdrew from the study as a result of adverse events. With regard to efficacy and clinical improvement in disease-specific features, the results presented herein are comparable with those of other ERTs (5, 6, 9).

One limitation of this study is that the number of patients was small and all patients were not naïve to ERT because of the rarity of this disease in Korea. Also, the study period was relatively short and there were dose differences among the study subjects. Although a small number of patients were recruited, this study is the first to investigate the safety and efficacy of Abcertin®.

In conclusion, the efficacy and safety of Abcertin® are similar to those of Cerezyme®; thus Abcertin® can be used as an alternative therapeutic agent for patients with type 1 Gaucher disease. As Cerezyme® is relatively expensive, Abcertin® is not only a useful treatment for patients with Gaucher disease but might also help to reduce costs.
