2309. Promoting Healthcare Worker (HCW) Use of Personal Protective Equipment in Pediatric Ambulatory Settings
Folasade Odemuyi, MPH1, Samantha Hanley, BA, Laureen Gianchetti, BA2, Anna Sharova, MPH3, Lori Handy, MD, Susan E. Coffin, MD, MPH, FSHEA, FPDID4 and Kristen Feenster, MD, MPH, MSHP5; Infectious Diseases, Children’s Hospital of Philadelphia, Philadelphia, Pennsylvania; 6Children’s Hospital of Philadelphia, Philadelphia, Pennsylvania; 7Department of Pediatrics, Division of Infectious Diseases, Children’s Hospital of Philadelphia, Philadelphia, Pennsylvania; 8Center for Pediatric Clinical Effectiveness, Pediatric Infectious Diseases Epidemiology and Antimicrobial Stewardship Research Group, Children’s Hospital of Philadelphia, Philadelphia, Pennsylvania; 9Division of Infectious Diseases, Department of Pediatrics, The Children’s Hospital of Philadelphia, Philadelphia, Pennsylvania

Session: 246. Pediatric Healthcare Associated Infections
Saturday, October 6, 2018: 12:30 PM

Background. Existing Centers for Disease Control (CDC) and American Academy of Pediatrics (AAP) guidelines promote HCW personal protective equipment (PPE) use to prevent respiratory virus transmission in pediatric clinics; however, adherence to recommendations is inconsistent. We evaluated the effectiveness of two strategies designed to cue HCW use of PPE in a pediatric primary care clinic.

Methods. We implemented two HCW-focused interventions: (1) prompt for front desk respiratory symptom screen with placement of droplet signs on examination room door for symptomatic patients and (2) universal masking of healthcare workers during all patient encounters. Each intervention was implemented over a 2-week period and preceded by a washout period. We obtained caregiver report of HCW hand hygiene and mask use during patient encounters and measured differences in the proportion of behavior observed compared with washout periods.

Results. We obtained 217 caregiver reports of clinician handwashing and mask use before, during and after the patient encounter. There was no difference in nurse pre- vs. post-intervention MD hand hygiene behavior before and after each intervention (Baseline 65.9%; Droplet: 73.3%, P = 0.34; Universal masking: 77.5%, P = 0.16 and Baseline 53.3%; Droplet: 66.6%, P = 0.14; Universal masking: 55%, P = 0.85, respectively). There was also no difference in pre- or post-encounter MD hand hygiene behavior before and after each intervention: (Baseline 86.9%; Droplet: 77.8%, P = 0.17; Universal masking: 87.5%; P = 0.92 and Baseline 75%; Droplet: 71.1%, P = 0.62; Universal masking: 80.0%; P = 0.53, respectively). However, there was a significant difference in observed mask use during encounters among both RNs and MDs before and after each intervention: (Baseline 17.4%; Droplet: 44.4%, P <0.05; Universal masking: 42.5%, P < 0.05 and Baseline: 20.6%; Droplet: 51.1%, P < 0.05; Universal masking: 62.5%, P < 0.05, respectively).

Conclusion. Respiratory symptom screening with visual prompts to use PPE and universal masking may not significantly impact hand hygiene behavior in a setting with high hand hygiene use but may increase mask use. Such interventions could provide a useful and low cost tool to help prevent the spread of respiratory viruses in primary care settings.

2310. Reasons Pediatric Providers Obtain Endothelial Aspirate Cultures and How Results Inform Patient Management
Anna-Sick-Samuels, MD, MPH1, Jim Fackler, MD,2, Pranita Tamma, MD, MHS3 and Aarôn M. Millstone, MD, MHS4; 1Pediatrics, Johns Hopkins University School of Medicine, Baltimore, Maryland, 2Pediatric Anesthesiology and Critical Care Medicine, Johns Hopkins University School of Medicine, Baltimore, Maryland, 3Johns Hopkins University School of Medicine, Baltimore, Maryland, 4FDISA, FSHEA, Pediatrics, The Johns Hopkins Medical Institutions, Baltimore, Maryland

Session: 246. Pediatric Healthcare Associated Infections
Saturday, October 6, 2018: 12:30 PM

Background. Endothelial aspirate cultures (EACs) are commonly obtained in many PICUs. However, EACs may not significantly impact hand hygiene behavior in a setting with high hand hygiene use but may increase mask use. Such interventions could provide a useful and low cost tool to help prevent the spread of respiratory viruses in primary care settings.

2311. Atypical Cat Scratch Disease Presentations
Ross Comiassof, B.S.1, Aliza Speth-Cook, B.S.1 and Guliz Erdem, MD2; Infectious Disease, Nationwide Children’s Hospital, Columbus, Ohio; 3Pediatrics, Nationwide Children’s Hospital and the Ohio State University School of Medicine, Columbus, Ohio

Session: 247. Pediatric Bacterial Infections
Saturday, October 6, 2018: 12:30 PM

Background. Cat scratch disease (CSD) is caused by B henselae, a Gram-negative intracellular bacilli which is transmitted to humans via cat bite/scratch. Typical CSD presents as regional lymphadenopathy and fever. However, atypical presentations of cat scratch disease that have been reported including prolonged fever, absence of lymphadenopathy and systemic complications such as hepatosplenic disease, osteomyelitis, Parinaud oculoglandular syndrome, neuroretinitis, encephalitis, and bacillary angiomatisom among other rare presentations. The aim of this study was to review the frequency, presentation, and treatment outcomes of atypical CSD presenta-
tions at Nationwide Children’s Hospital (Columbus OH).

Methods. This was a retrospective study performed at Nationwide Children’s Hospital, Columbus, OH. EMR of patients with atypical CSD were reviewed between January 2010 and March 2017 using ICD9 or ICD 10 codes for CSD. Patients were identified on the basis of compatible clinical presentation and confirmatory serological test or PCR results for B. henselae. Clinical, radiological, and histopathological findings were collected.

Results. A total of 204 patients were serologically diagnosed as having cat scratch disease between January 2010 and July 2017. Of the 204 cases, 166 (81%) had typical CSD and 38 (18.6%) had atypical CSD. Of the atypical manifestations, 20 (52%) patients had no lymphadenopathy, 12 (31%) had osteomyelitis, 12 (31%) patients had hepatic and/or splenic microabscesses, 4 (10.5%) had osteomyelitis and hepatic/splenic involvement, 3 (11.6%) had neuroretinitis. 2 (5.2%) had neurinomas, and there was one case each of 2.6% of Parinaud oculoglandular syndrome, uveitis, pulmonary cavitary lesion, myocarditis, and endocarditis. Fever of unknown origin was present in 28 (75.6%) of the atypical CSD cases. The median duration of antibiotic treatment was 25 days (IQR 56). The majority of patients were treated with dual antibiotic therapy that included rifampin. Conclusion. In children with fever of unknown origin, serologic testing for CSD should be performed even in the absence of lymphadenopathy and a search for underlying systemic complications is recommended for prompt diagnosis and appropriate treatment.

2312. Bordetella holmesii Bacteremia in Pediatric Patients: A Single-Center Experience
Sis Jin Joo, MD1; Cassie Grimsley-Ackerley, MD2; Andres Camacho-Gonzalez, MD, MSC3; Preeti Jaggi, MD3 and Mark Gonzalez, PhD4; 1Division of Pediatric Infectious Diseases, Emory University School of Medicine, Atlanta, Georgia, 2Georgia’s Children’s Healthcare of Atlanta, Atlanta, Georgia

Session: 247. Pediatric Bacterial Infections
Saturday, October 6, 2018: 12:30 PM

Background. Bordetella holmesii is a respiratory pathogen, known to cause bacteremia predominantly among patients with functional or anatomical asplenia. Currently, there is no consensus on optimal treatment for B. holmesii infection nor are there established interpretative criteria. This study aims to describe treatment of pediatric patients diagnosed with B. holmesii bacteremia, and treatment outcomes, in order to help establish an optimal therapeutic strategy.

Methods. We conducted a retrospective chart review of pediatric patients with microbiologically confirmed B. holmesii bacteremia at Children’s Healthcare of Atlanta, Atlanta, 2011–2018. We extracted demographic and clinical information of the iden-
tified patients from the medical record, and evaluated antimicrobial choice, hospital stays, and modified in 16% based on the EAC results. Antibiotics were changed based on a different test in 52%, or unchanged in 20%. Of the patients with a prior EAC, 72% of EACs resulted the same or fewer bacteria. On follow-up, 56% of the providers reported the EAC provided little to no value for the patient’s management. Conclusion. A large proportion of EACs were obtained due to isolated changes in a patient’s clinical status and most EACs were obtained from patients who had prior EACs. Results were often similar to prior EAC results, infrequently led to changes in antibiotic selection and many providers did not find the results helpful. These findings suggest there is opportunity to standardize and reduce the use of EACs in the PICU.

Disclosures. All authors: No reported disclosures.
Results. Seven patients were identified; all had sickle cell disease and five had moderate to severe asthma requiring controller medications. They presented to the emergency department with mild respiratory illness with fevers, but had hemodynamic stability. Peripheral blood cultures were obtained and intravenous ceftriaxone was administered as the empiric antibiotic therapy. Six patients were discharged home after evaluation and treatment for acute chest syndrome with venoocclusive crisis (see figure). When the blood cultures grew B. holmesii, previously discharged patients were called back for follow-up; three were admitted, and only one patient had a subsequent blood culture growing B. holmesii. Hospitalization days ranged from 3 to 5 days, and two patients went home with oral ciprofloxacin at the time of discharge. Total antibiotic days ranged from 1 to 15 days among the seven patients. No one required an intensive level care, and all were asymptomatic without recurrence of B. holmesii infections at the post-discharge follow-up.

Conclusion. In our pediatric patients with B. holmesii bacteremia, clinical recovery was favorable with no severe illness, despite widely different treatment regimens and length of therapy. The questions still remain regarding pathogenicity of B. holmesii infection and efficacy of antibiotic use.

2313. Risk of Relapsed or Persistent Infection Caused by Enterobacter Species in Children

Juri Boguniewicz, MD; Paula Revell, PhD and Debra Palazzi, MD, Med; Baylor College of Medicine and Texas Children’s Hospital, Houston, Texas

Session: 247. Pediatric Bacterial Infections Saturday, October 6, 2018: 12:30 PM

Background. Enterobacter species are a major cause of infections in hospitalized children. Treatment is complicated by the presence of a chromosomal AmpC β-lactamase, capable of inactivating certain antibiotics, including third-generation cephalosporins (3GC). Previous studies in adults have reported a 3–19% risk of relapsed bacteremia with 3GC therapy. Data in children regarding risk factors predicting relapse or persistence of infection are lacking. We sought to determine the frequency of and risk factors for relapse or persistence of Enterobacter infection in children.

Methods. Retrospective study of patients ≥21 years old admitted to Texas Children’s Hospital 2012, 2015 and 2016 with bacteremia due to Enterobacter species. Risk factors for relapse or persistence of bacteremia 72 hours and up to 30 days after initial positive blood culture were evaluated; relapsed infection at secondary sites was also evaluated.

Results. 58 individual patients with bacteremia due to Enterobacter species were identified; most (58%) were immunosuppressed and 19 (32.8%) were critically ill. The majority (75.9%) had primary bacteremia; 82.8% had a central line. An intra-abdominal source was identified in 6 (10.3%) patients. Seventeen (29.3%) patients had initial Enterobacter isolates resistant to 3GCs. Of the 41 patients with 3GC-susceptible isolates, 5 (12.2%) had relapse or persistence of infection; 2 of these developed relapse with an isolate resistant to 3GCs. Among the relapsed cases, those who developed resistant isolates had uncontrolled intra-abdominal or biliary sources of infection. Treatment with a 3GC was not associated with increased risk of relapse or persistence of infection (OR 2.1; 95% CI, 0.3–14.2, P = 0.45). Source control was inadequate in all cases of relapsed bacteremia. Relapsed cases with primary bacteremia cleared their bacteremia with central line removal. One patient with relapsed infection died.

Conclusion. The incidence of relapsed or persistent Enterobacter infection after initial bacteremia is comparable to previous adult studies. However, treatment of 3GC-susceptible isolates with 3GCs did not result in higher rates of treatment failure. Initial bacteremia is comparable to previous adult studies. However, treatment of 3GC-susceptible isolates with 3GCs did not result in higher rates of treatment failure.

2315. Neisseria meningitidis Oro-Pharyngeal Carriage, Serogroups and Clonal Complex in Children and Adolescents in Argentina

Angela Gentile, MD1; Maria Paula Della Latta, MD2; Barbara Wisner, Biochemist3; Mercedes Bloch, MD3; Luisa Martorelli, PhD2; Cecilia Sorhouet Pereira, Biochemist4; Mabel Regueiras, MD; Maria Del Valle Juarez, MD5; Veronica Umido, MD5; and Adriana Efron, Biochemist6; 1Epidemiology, Hospital of Niños “Ricardo Gutiérrez”, Buenos Aires, Argentina; 2Emergency Department, Hospital of Niños “Ricardo Gutiérrez”, Buenos Aires, Argentina; 3Buenos Aires, Argentina; 4Instituto de Infectología, Buenos Aires, Argentina; 5Department of Laboratory Medicine, Nationwide Children’s Hospital, Columbus, Ohio; 6Department of Laboratory Medicine, Nationwide Children’s Hospital, Columbus, Ohio

Session: 247. Pediatric Bacterial Infections Saturday, October 6, 2018: 12:30 PM

Background. Neisseria meningitidis (Nm) pharyngeal carriage is a necessary condition for invasive meningococcal disease. In 2017, Argentina introduced a tetra-valent meningococcal conjugated vaccine (MenACYW) to the National Immunization Program for children. We present the first carriage study in children in the prevaccine era. Aims: 1) to assess the rate of Nm carriage in healthy children and adolescents attending a public hospital in Buenos Aires city; 2) to determine serogroup and clonal complex distribution; 3) to determine carriage risk factors by age. Methods. Cross-sectional study including children 1–17 years, stratified in two age groups (1–9 years and 10–17 years) assisted at Ricardo Gutiérrez Children Hospital between March–December 2017. Oro-pharyngeal swabs were plated and meningococci identified by conventional microbiology methods. Serogroup was determined by PCR, clonal complex was determined by MLST.

Results. A total of 1751 children were included. Group aged 1–9 years: 38 Nm were isolated from 943 samples collected: overall carriage 4.0%. Serogroups distribution: B 26.3%, Y 2.6%, W 5.3%, Z 5.3%, non-encapsulated 79.9% and non-capsulated 52.6%. Clonal complex was determined for 25 isolates. Attendance at social venues was the only independent predictor of Nm carriage (adjusted OR: 2.02, CI 95% = 1.01–4.03; P = 0.04). Group aged 10–17 years: 76 Nm were isolated from 808 samples: overall carriage 9.4%. Serogroups distribution: B 19.7%, C 5.3%, W 7.9%, Y 9.2%, Z 5.3%.
