Abstract: We propose a simple unfolded description of free massive higher spin particles in anti-de-Sitter spacetime. While our unfolded equation of motion has the standard form of a covariant constancy condition, our formulation differs from the standard one in that our field takes values in a different internal space, which for us is simply a unitary irreducible representation of the symmetry group. Our main result is the explicit construction, for the case of AdS$_3$, of a map from our formulation to the standard wave equations for massive higher spin particles, as well as to the unfolded description prevalent in the literature. It is hoped that our formulation may be used to clarify the group-theoretic content of interactions in higher spin theories.
1 Introduction and Summary

The study of relativistic wave equations, whose solution spaces carry unitary irreducible representations of the spacetime symmetry group, lay at the birth of quantum field theory and was undertaken by several towering figures in the field. For example, in 1939 Fierz and Pauli [1] wrote down equations describing free, massive particles transforming as a symmetric rank $s$ tensor:

$$(\Box - M^2)\phi_{\mu_1...\mu_s} = 0, \quad \nabla^\mu \phi_{\mu\mu_2...\mu_s} = 0,$$  \hspace{1cm} (1.1)

where $\phi_{\mu_1...\mu_s}$ is a totally symmetric traceless tensor. In the anti-de Sitter space $\text{AdS}_{d+1}$ the set of solutions of these equations, upon imposing suitable boundary conditions, form a unitary, irreducible representation $D(\Delta, s)$ of the symmetry algebra $so(2, d)$ with lowest energy $\Delta$, where

$$M^2 = \Delta(\Delta - d) - s.$$  \hspace{1cm} (1.2)

– 1 –
We refer to [2] for a modern review of relativistic wave equations and references to the original literature.

In recent years a different yet equivalent formulation of relativistic wave equations has proven useful, namely the unfolded formulation due to Vasiliev and collaborators (see [3] for a review). In this formulation, covariant wave equations like (1.1) are replaced by a system of coupled first-order equations typically containing an infinite number of auxiliary fields. A beautiful feature of unfolded equations is that they geometrize covariant wave equations like (1.1), since they can be interpreted as a covariant constancy condition on a section of a certain vector bundle over AdS$_{d+1}$. Unfolded equations were first proposed for massless higher spins in (A)dS$_4$ [4], and subsequently generalized to other dimensions, massive fields and flat backgrounds [5]-[14]. One advantage of the unfolded formulation is that it facilitates the coupling of massive fields to massless higher spin gauge fields, and therefore it lies at the core of Vasiliev’s construction of interacting higher spin theories [15],[16]. This has in turn played an important role in recently uncovered examples of holographic duality, where bulk Vasiliev theories were argued to be dual to holographic boundary CFTs possessing conserved currents of spin greater than two.

One example in the context of AdS$_3$/CFT$_2$ holography is the minimal model holography proposed by Gaberdiel and Gopakumar [17]. Here, the bulk theory contains a massive scalar field with mass $m^2 = \lambda^2 - 1$, which is coupled to massless higher spin fields with $hs[\lambda]$ gauge symmetry through unfolded equations [8],[9]. A second example, which inspired the current work, is provided by the tensionless limit of string theory on the AdS$_3 \times S^3 \times T^4$ background with Ramond-Ramond flux. In this case, the bulk theory contains massless higher spin fields with a gauge symmetry which goes under the name of the ’higher spin square’ (HSS)$^1$ [18],[19],[20]. Furthermore, the symmetric orbifold CFT contains many spinning primaries with spins $s = |\hbar - \bar{\hbar}| \in \mathbb{N}/2$ which in the bulk correspond to massive higher spin fields. As in the example above, it is therefore desirable to have an unfolded description of the massive higher spin equations (1.1). In [23], one of us proposed a linearized unfolded equation describing the massive higher spin fields in the untwisted sector in the background of a HSS gauge field. When restricted to a pure spin-two background, one notices that this equation gives a different and, we feel, simpler unfolded description of massive HS fields than the ones in the literature.

In this work, we clarify the relation between this unfolded formulation of massive higher spins in AdS$_3$ and the standard one. In both formulations, the basic field $C(x)$ is a zero-form section of a vector bundle over AdS$_3$, taking values in an infinite-dimensional representation $R$ of the symmetry algebra $so(2,d)$. The field equations simply state that $C(x)$ is covariantly constant:

$$ (d + A_R) C = 0. $$

(1.3)

In this equation, $A$ stands for the flat AdS$_{d+1}$ connection made out of the vielbein and spin connection

$$ A = e^a P_a + \frac{1}{2} \omega^{ab} M_{ab}. $$

(1.4)

$^1$Recently, it was shown [21],[22] that the symmetric orbifold CFT also describes a subsector of the tensionless limit of string theory on the S-dual background with NS-NS flux.
The subscript $R$ in (1.3) means that the generators are taken in the representation $R$. The equation (1.3) states that the general solution is obtained by picking an arbitrary vector $C_0$ at the origin and parallel transporting it. In terms of the group element $G$ in writing $A = G^{-1}dG$, the general solution is $C(x) = G^{-1}_R(x)C_0$.

In the standard unfolded formulation [8],[9],[14] for a massive spin-$s$ field on AdS$_3$, the representation $R$ acts on basis vectors $V_a^{(t)}$, with $|a| \leq t$ and $t = s, s+1, \ldots$, which for fixed $t$ transform as a spin-$t$ representation under the Lorentz subalgebra $so(1,2)$. The AdS translation generators act on these as in formula (3.77) below. In the most widely known example describing a spin-0 field, the $V_a^{(t)}$ are generators of the higher spin algebra $hs[\lambda]$ and the action of the AdS translation generators comes from the ‘lone-star’ product. The resulting system of equations are equivalent to the Fierz-Pauli description (1.1), since one can prove a ‘central on mass-shell’ theorem which states that the lowest spin-$s$ component of $C$ is precisely the Fierz-Pauli field $\phi_{\mu_1\ldots\mu_s}$ above.

In this work, we will explore a different unfolded formulation, where the representation $R$ in (1.3) is instead simply taken to be the unitary irreducible representation $D(\Delta, s)$ itself. One advantage of this formulation is that the space of solutions to (1.3) forms a Hilbert space with inner product inherited from $D(\Delta, s)$. While for this choice for $R$ the fact that (1.3) gives a field theory realization of $D(\Delta, s)$ is almost tautological, it is not a priori clear if there is an analogue of the central on mass-shell theorem allowing one to reconstruct the Fierz-Pauli field from $C$, nor how this unfolded formulation is related to the standard one. The main goal of this work is to address these questions. A key property is that the generators $V_a^{(t)}$ of the standard unfolded formulation can be constructed as non-normalizeable states in the $D(\Delta, s)$ Hilbert space. This allows us to construct a linear map or ‘intertwiner’ between the two representations, and construct from our field the unfolded field of the standard formulation. The restriction to the spin-$s$ component of the latter then leads to the desired on mass-shell theorem. As a corollary, our results allow for a completely algebraic construction of the mode solutions of the Fierz-Pauli equations, see equation (3.90) below.

Since in the present unfolded formulation, the group theoretic meaning is completely transparent and involves only the representation $D(\Delta, s)$, it may be hoped that it may shed light on the group-theoretic content of the interaction vertices in Vasiliev theory. This may be of use in constructing as yet unknown interactions in the theory based on the higher spin square. As a first step towards such a construction, we will show in a separate publication how the equation proposed in [23] combines an infinite set of our massive higher spin equations of the form (1.3) into a single multiplet of the higher spin square.

2 Simple Unfolded Equations on AdS$_{d+1}$

In this section, we review some aspects of the geometry of AdS$_{d+1}$ and propose and analyze our unfolded equations.
2.1 Coset Description

We start out by recalling the coset description of anti-de Sitter space. The \( d+1 \)-dimensional anti-de Sitter spacetime \( \text{AdS}_{d+1} \) can (up to global issues which are not relevant at present) be described as the homogenous symmetric space \( \text{SO}(2,d)/\text{SO}(1,1) \), where the isotropy subgroup \( \text{SO}(1,d) \) is the Lorentz group in \( d+1 \) dimensions. We will denote by \( M_{AB} \), \( A,B = 0',0,\ldots,d \) the generators of the Lie algebra \( \text{so}(2,d) \) with commutation relations

\[
[M_{AB},M_{CD}] = i (\eta_{BC}M_{AD} - \eta_{AC}M_{BD} - \eta_{BD}M_{AC} + \eta_{AD}M_{BC}),
\]

where \( \eta_{AB} = \text{diag}(- - + \ldots +) \). In a unitary representation, the \( M_{AB} \) are represented by Hermitian operators. We will split them up in ‘AdS translations’, i.e. the coset generators \( P_a = M_{0'a} \), \( a = 0,\ldots,d \), and Lorentz generators \( M_{ab} \in \text{SO}(1,d) \). They satisfy

\[
[P_a,P_b] = iM_{ab},
\]

\[
[M_{ab},P_c] = -2i\eta_{cl}[P_b],
\]

\[
[M_{ab},M_{cd}] = -2i\eta_{cl}[M_{bd} + 2i\eta_{dl}[M_{bc}].
\]

(2.2)

Due to homogeneity, points in \( \text{AdS}_{d+1} \) can be viewed as coset representatives \( G(x) \in \text{SO}(2,d) \), for example we could use a ‘canonical’ parametrization where \( G(x) = \exp x^aP_a \).

The infinitesimal version of this relation, setting \( g = 1 + \epsilon^{AB}M_{AB} \), defines the Killing vectors \( l_{\mu}^{AB} \partial_{\mu} \) through \( x'^{\mu} = x^{\mu} - \epsilon^{AB}l_{\mu}^{AB} \) and what we will call the ‘Lorentz-compensator’ fields \( W_{AB}^{\mu} \) through \( h = 1 - \frac{1}{2}\epsilon^{AB}W_{AB}^{\mu}M_{\mu} \). It follows from (2.3) that these satisfy

\[
G^{-1}M_{AB}G = -l_{\mu}^{AB}G(x)^{-1}\partial_{\mu}G(x) - \frac{1}{2}W_{AB}^{\mu}M_{\mu}.
\]

(2.4)

It can be shown that the Killing vectors \( l_{\mu}^{AB} \) obey the same commutation relations (2.1) as the generators \( M_{AB} \). We refer to [24] for a proof and a review of the differential geometry of coset spaces.

From the coset representative we construct the flat \( \text{so}(2,d) \)-valued connection

\[
A = G^{-1}dG.
\]

(2.5)

It can be decomposed into vielbein and spin connection parts as follows

\[
A = e^aP_a + \frac{1}{2}\omega^{ab}M_{ab} \equiv e + \omega.
\]

(2.6)

Using this relation in (2.4), one finds an expression for the Killing vectors and Lorentz compensators in terms of the vielbein, spin connection and adjoint representation components of \( G \):

\[
l_{\mu}^{AB} = -e_{a}^{\mu}(G^{-1}M_{AB}G)^{a}
\]

\[
W_{AB}^{\mu} = -(G^{-1}M_{AB}G)^{\mu} - l_{\mu}^{AB}\omega^{\mu}_{\mu}.
\]

(2.7)

(2.8)

\(^2\)Note that we set the AdS radius to one.
2.2 Unfolded equations

Following Wigner’s definition, a quantum mechanical particle can be identified with a unitary, irreducible representation of the spacetime symmetry group in which the energy is bounded from below. In the case of AdS\(_{d+1}\), particle representations are built on a set of primary states \(|\Delta, s\rangle\) which form a unitary irreducible representation of the maximal compact subalgebra so(2) \(\oplus\) so\(_d\). Here, \(\Delta\) is the eigenvalue of the energy operator \(P_0\) while \(s\) denotes quantum numbers specifying a unitary irreducible representation of so\(_d\). The states \(|\Delta, s\rangle\) are annihilated by the energy lowering operators
\[
J^-_a = M_{0a} + iP_a.
\]

The representation is built up by acting on the states \(|\Delta, s\rangle\) with the energy raising operators \(J^+_a = M_{0a} - iP_a\) and will be denoted by \(D(\Delta, s)\). If \(s\) is a totally symmetric rank-\(s\) tensor, the quadratic Casimir takes the value
\[
\frac{1}{2}M_{AB}M^{AB} = \Delta(\Delta - d) + s(s + d - 2).
\]

By a field theory realization of the particle representation \(D(\Delta, s)\), we mean a set of spacetime-dependent fields which satisfy a set of equations (and possibly boundary conditions) which are invariant under the spacetime isometry algebra, such that the solution space transforms as the representation \(D(\Delta, s)\). For example, the Fierz-Pauli equations (1.1) in AdS\(_{d+1}\) give, upon imposing suitable boundary conditions, a field theory realization of the representation\(^3\) \(D(\Delta, s)\), where \(s\) stands for the symmetric rank \(s\) tensor representation.

As anticipated in the Section 1, we will now show that an alternative field theory realization of a particle representation \(R = D(\Delta, s)\) is provided by the system of equations
\[
(d + A_R)C(x) = 0.
\]

where \(C(x)\) is a zero-form which takes values in an internal space which is precisely the representation space \(R\). The connection \(A\) is the AdS\(_{d+1}\) connection (2.6), and the subscript \(R\) means that the generators in (2.6) are taken in the representation \(R\). For notational simplicity, we will drop this subscript in what follows. Note that the equation (2.11) is integrable due to the fact that \(A\) is a flat connection.

2.3 Lorentz and Diffeomorphism Covariance

Let us first show the covariance of the equations (2.11) under diffeomorphisms and local Lorentz transformations. For this, we observe that the equations are gauge-invariant under local \(SO(2,d)\) transformations under which both the background \(A\) and the field \(C\) transform, in the following way:
\[
A \rightarrow \Lambda(A + d)\Lambda^{-1}
\]
\[
C \rightarrow \Lambda C
\]

\(^3\)This statement holds only for \(d > 2\). For AdS\(_3\), where the subgroup of spatial rotations reduces to so(2), we will review in Section 3.3 below that the Fierz-Pauli equations describe two irreducible representations with opposite signs of the spatial so(2) helicity.
When $\Lambda = \exp(\lambda^{ab}(x)M_{ab})$ belongs to the Lorentz subgroup $SO(1,d)$, these transformations encode the covariance of the equation (2.11) under local Lorentz transformations. Indeed, the first equation (2.12) implies, using the commutation relations (2.2), the standard transformation of the vielbein and spin connection under local Lorentz transformations. The second equation (2.13) elucidates the Lorentz transformation character of our master field $C$: it transforms as the representation $R$, decomposed under the Lorentz subalgebra $so(1,d)$. Therefore, $C$ doesn’t transform irreducibly under Lorentz transformations in general, in contrast to e.g. symmetric tensor field of the Fierz-Pauli system. We note that the equation (2.11) can be rewritten as

\[(\nabla + e^aP_a)C = 0 \quad (2.14)\]

where

\[\nabla \equiv d + \frac{1}{2} \omega^{ab}M_{ab} \quad (2.15)\]

is the Lorentz covariant derivative.

Similarly, it can be shown that taking $\Lambda = \exp(\lambda^a(x)P_a)$ encodes covariance under local diffeomorphisms, albeit mixed with local Lorentz transformations (see [25] for details).

### 2.4 Orthonormal Basis of Solutions

The equations of motion (2.11) imply that $C$ is a covariantly constant section, and therefore the general solution can be obtained by picking an arbitrary value $C_0 \in R$ to be the value of $C$ in the origin $x = 0$ (which we take to correspond to the identity, $G(0) \equiv 1$) and parallel transporting it:

\[C(x) = G(x)^{-1}C_0. \quad (2.16)\]

Since the representation $R$ is unitary, the space of solutions to (2.11) has the structure of a Hilbert space, where the inner product is defined as

\[(C, C') \equiv (C(x), C'(x))_R = (C_0, C'_0)_R. \quad (2.17)\]

Here, $(\cdot, \cdot)_R$ is the inner product on $R$. The result is independent of $x$ due to (2.16) and unitarity.

If $\{e_p\}_p$ forms an orthonormal basis of $R$, a complete orthonormal basis of solutions is given by $\{C_p\}_p$ with

\[C_p(x) = G^{-1}(x)e_p. \quad (2.18)\]

### 2.5 Global AdS$_{d+1}$ Symmetry

For a fixed background $\mathcal{A}$, i.e. a specific choice for the AdS$_{d+1}$ vielbein and spin connection, the global symmetries of eq. (2.11) are the subset of transformations (2.12, 2.13) which leave $\mathcal{A}$ invariant. From (2.16), it is easy to see that these are generated by infinitesimal gauge parameters of the form $\lambda_{AB} = G^{-1}M_{AB}G$, which obviously generate the anti-de-Sitter algebra $so(2,d)$. Their action on the field $C$ is

\[\delta_{AB}C = G^{-1}M_{AB}GC. \quad (2.19)\]
The basis of solutions (2.18) transforms precisely as the representation $R$ of the symmetry algebra:
\[ \delta_{AB} C_p = (M_{AB})_p^q C_q, \]  
where the indices $p, q$ refer to components in the representation $R$. It is therefore clear that (2.11) provides a field theory realization for the particle representation $R$.

Using the equation of motion (2.11) and the identity (2.4), we can reexpress the right-hand side of (2.19) as the action of the scalar Lie derivative plus an ‘internal’ part determined by the Lorentz compensator given in (2.8):
\[ \delta_{AB} C = l^a_{AB} \partial_a C - \frac{1}{2} W^{ab}_{AB} M_{ab} C = l^a_{AB} \nabla_a C + \frac{1}{2} (G^{-1} M_{AB} G)^{ab} M_{ab} C, \]  
where in the second equality we have used (2.8). We note that the second order Casimir differential operator constructed from $\delta_{AB}$ is constant, for example for the symmetric tensor representation $D(\Delta, s)$ it evaluates to
\[ \frac{1}{2} \delta_{AB} \delta^{AB} C = \frac{1}{2} M_{AB} M^{AB} C = (\Delta(\Delta - d) + s(s + d - 2)) C. \]  

We end this section with some comments:

• The unfolded equations (2.11) are consistent for general representations $R$, for example the representation $s$ in $D(\Delta, s)$ is not restricted to be a symmetric tensor but can have mixed symmetry. Though we will focus on the massive case, where $D(\Delta, s)$ is a ‘long’ multiplet, in what follows, the above unfolded description also applies to the massless or partially massless cases, when $D(\Delta, s)$ saturates a unitarity bound and becomes ‘short’. The representation $R$ in (2.11) could in principle even be non-unitary, though of course in this case the solutions would not form a Hilbert space.

• The unfolded description in this section generalizes in a straightforward manner to Minkowski space (the coset $\text{Poincaré}_{d+1}/SO(1,d)$) and de Sitter space (the coset $SO(1,d+1)/SO(1,d)$).

• While our unfolded equations carry by construction a representation of the AdS$_{d+1}$ symmetry algebra, and therefore also of the simply connected part of the symmetry group, they are not guaranteed to be invariant under additional discrete symmetries (such as parity in $d = 2$, as we shall illustrate below). To construct a system invariant under an additional discrete $\mathbb{Z}_2$ symmetry may require considering a doublet of fields $C, \tilde{C}$ which are exchanged by the discrete symmetry.

3 Unfolded Massive Higher Spin Equations in AdS$_3$

Our proposed unfolded equations (2.11) give a simple field theory realization of an arbitrary particle representation of the symmetry group. However, they do so at the cost of introducing an infinite number of fields: since unitary representations are infinite dimensional, the field $C$ has an infinite number of components. Most of these components are
expected to be in some sense auxiliary, and it will be the goal of this section to understand how to extract the physical components of \( C \), focusing on the case of AdS\(_3\) and on massive particle representations case for simplicity. In this case, we will find the explicit linear combinations of components of our master field \( C \) which satisfy the topologically massive equations (3.50). This provides a version of the ‘central on mass-shell’ theorem for our unfolded equations. In deriving this result, we will also find a map from our master field \( C \) to the field obeying the unfolded equations of [14].

3.1 \( sl(2, \mathbb{R}) \oplus \overline{sl(2, \mathbb{R})} \) Basis

Let us first specialize the general equations of the previous section to the case of AdS\(_3\). The three-dimensional case is somewhat special in that symmetry algebra is not semisimple, \( so(2, 2) \cong sl(2, \mathbb{R}) \oplus \overline{sl(2, \mathbb{R})} \), and it will be convenient to work in a basis \( L_m, \bar{L}_m, m = -1, 0, 1 \) adapted to this decomposition. The commutation relations are

\[
[L_m, L_n] = \epsilon_{mnp} \eta^{pq} L_q = (m - n)L_{m+n},
\]

\[
[\bar{L}_m, \bar{L}_n] = \epsilon_{mnp} \eta^{pq} \bar{L}_q = (m - n)\bar{L}_{m+n},
\]

\[
[L_m, \bar{L}_n] = 0.
\]

Here, the \( \epsilon \)-tensor is defined to have \( \epsilon_{-101} = 2 \) and \( \eta^{mn} \) is the inverse of

\[
\eta_{mn} = \begin{pmatrix}
0 & 0 & -2 \\
0 & 1 & 0 \\
-2 & 0 & 0
\end{pmatrix}.
\]

The latter is proportional to the Cartan-Killing form which we normalize as

\[
K(L_m, L_n) = K(\bar{L}_m, \bar{L}_n) = \frac{1}{2} \eta_{mn}, \quad K(L_m, \bar{L}_n) = 0.
\]

The generators can be combined into \( AdS \)-translation generators \( P_m \) and Lorentz generators \( M_m \), which generate the diagonal \( sl(2) \) subalgebra, as follows

\[
P_m = L_m - \bar{L}_m, \quad M_m = L_m + \bar{L}_m.
\]

In terms of the original \( so(2, 2) \) generators \( M_{AB}, A, B = 0', 0, 1, 2 \) introduced in (2.1), these are given by

\[
P_0 = M_{00'}, \quad M_0 = M_{12},
\]

\[
P_{\pm 1} = M_{01} \pm i M_{02}, \quad M_{\pm 1} = M_{02} \mp i M_{01}.
\]

We note that in unitary representations of \( sl(2, \mathbb{R}) \), the generators must satisfy \( L_0^1 = L_0, \ L_{\pm 1}^1 = L_{\mp 1} \), and similarly for the barred generators. The generators of the maximal compact subalgebra \( so(2) \oplus so(2) \) are the energy operator \( P_0 = L_0 - \bar{L}_0 \), which generates global time translations, and the helicity operator \( M_0 = L_0 + \bar{L}_0 \) which generates spatial \( U(1) \) rotations.
The AdS$_3$ connection splits into $sl(2,R)$ and $\overline{sl}(2,R)$ parts:

$$\mathcal{A} = e^m P_m + \omega^m M_m = A^m L_m + \bar{A}^m \bar{L}_m,$$

where

$$A^m = \omega^m + e^m, \quad \bar{A} = \omega^m - e^m.$$  \hfill (3.9)

Noting that the coset element $G$ splits as

$$G(x) = g(x)\bar{g}(x), \quad g \in SL(2,R), \quad \bar{g} \in \overline{SL}(2,R),$$

we can work out the equations (2.8) for the Killing vectors and Lorentz compensator to find

$$l^\mu_m = -\frac{1}{2}(g^{-1}L_m g)^n e^\mu_n, \quad \bar{l}^\mu_m = \frac{1}{2}(\bar{g}^{-1}\bar{L}_m \bar{g})^n e^\mu_n$$

$$W^m_n = -l^\mu_m \bar{A}^\mu_n, \quad \bar{W}^m_n = -\bar{l}^\mu_m A^\mu_n.$$  \hfill (3.12)

From (3.12), we can derive the following useful identities involving the Killing vectors:

$$\eta^{mn} l^\mu_m l^\nu_n = \frac{1}{4} g^{\mu\nu}, \quad \eta^{mn} \bar{l}^\mu_m \bar{l}^\nu_n = \frac{1}{4} \bar{g}^{\mu\nu},$$

$$\nabla_{[\mu} (l_{\nu}]_\rho) = l^\mu_{\rho} e^\eta_{\mu\nu\rho\eta}, \quad \nabla_{[\rho} (\bar{l}_{\nu}]_\mu) = -l^\mu_{\rho} e^\eta_{\mu\nu\rho\eta}.$$  \hfill (3.14) (3.15)

To derive the identities in the second line we have used the flatness of $A$.

It is a simple exercise to find explicit expressions of the above quantities in the Poincaré coordinate system. We take the group elements $g, \bar{g}$ to be

$$g = e^{x+L_1} e^{\rho L_0}, \quad \bar{g} = e^{x-\bar{L}_1} e^{-\rho \bar{L}_0}.$$  \hfill (3.16)

This leads to

$$A = L_0 d\rho + e^\rho L_1 dx_+, \quad \bar{A} = -\bar{L}_0 d\rho + e^\rho \bar{L}_1 dx_-$$

$$e = P_0 d\rho + \frac{1}{2} e^\rho P_1 dx_+ - \frac{1}{2} e^\rho P_- dx_-, \quad \omega = \frac{1}{2} e^\rho M_1 dx_+ + \frac{1}{2} e^\rho M_- dx_-.$$  \hfill (3.17) (3.18)

Computing the metric one indeed finds the AdS$_3$ metric in Poincaré coordinates:

$$ds^2 = K(e,e) = d\rho^2 + e^{2\rho} dx_+ dx_-.$$  \hfill (3.19)

For the Killing vectors one finds, from (3.12),

$$l_{-1} = e^{-2\rho} \partial_- + x_+ \partial_\rho - x^2_+ \partial_+ , \quad \bar{l}_{-1} = -\partial_- ,$$

$$l_0 = -\frac{1}{2} \partial_\rho + x_+ \partial_+ , \quad \bar{l}_0 = -x_- \partial_+ + \frac{1}{2} \partial_\rho ,$$

$$l_1 = -\partial_+ , \quad \bar{l}_1 = -x^2_- \partial_+ + x_- \partial_\rho + e^{-2\rho} \partial_+.$$  \hfill (3.20) (3.21) (3.22)
3.2 Particle Representations

In this section, we will give explicit matrix elements for the unitary representations $D(\Delta, s)$ in the $sl(2, \mathbb{R}) \oplus sl(2, \mathbb{R})$ basis. We start by reviewing and introducing some notation for the highest- and lowest-weight representations of the $sl(2, \mathbb{R})$ Lie algebra, which are the only ones relevant for our purposes. We refer to [26], [27] for reviews of $sl(2, \mathbb{R})$ representation theory.

The lowest weight infinite-dimensional representations $D_+^\pm(h)$, for $2h \neq \mathbb{Z}^-$, are built on a lowest weight or primary state $|0\rangle_h$ satisfying

$$L_1|0\rangle_h = 0, \quad L_0|0\rangle_h = h|0\rangle_h.$$

(3.23)

If the primary state is normalized, $\langle 0|0\rangle_h = 1$, the normalized states in the representation are labelled as $|m\rangle_h$, $m \in \mathbb{N}$ and given by

$$|m\rangle_h = (m!((2h)(2h+1)\ldots(2h+m-1))^{-\frac{1}{2}}(L_{-1})^m|0\rangle_h$$

(3.24)

The generators are represented in this basis as

$$L_{-1}|m\rangle_h = ((m+1)(2h+m))^{\frac{1}{2}}|m+1\rangle_h$$

(3.25)

$$L_0|m\rangle_h = (h+m)|m\rangle_h$$

(3.26)

$$L_1|m\rangle_h = (m(2h+m-1))^{\frac{1}{2}}|m-1\rangle_h.$$

(3.27)

For later convenience, we note that the generators can be written in ket-bra notation as

$$L_{-1} = \sum_{m \in \mathbb{N}} ((m+1)(2h+m))^{\frac{1}{2}}|m+1\rangle_h\langle m|$$

(3.28)

$$L_0 = \sum_{m \in \mathbb{N}} (h+m)|m\rangle_h\langle m|$$

(3.29)

$$L_1 = \sum_{m \in \mathbb{N}} ((m+1)(2h+m))^{\frac{1}{2}}|m\rangle_h\langle m+1|.$$

(3.30)

Using these expressions one checks that, on $D_+^+(h)$, the quadratic Casimir

$$C_2 \equiv \eta^{mn}L_mL_n = L_0^2 - \frac{1}{2}(L_1L_{-1} + L_{-1}L_1)$$

(3.31)

takes the value

$$C_2 = h(h-1).$$

(3.32)

The representations $D_+^+(h)$ are unitary for $h > 0$.

We will also consider the conjugate representations $D_-(h)$ for $2h \neq \mathbb{Z}^-$, whose weights are sign-reversed compared to those of $D_+^+(h)$. These are infinite-dimensional highest weight representations built on a highest weight or anti-primary state with $L_0$-eigenvalue $-h$, and are unitary for $h > 0$. The quadratic Casimir takes again the value (3.32). The states in these representations can be conveniently denoted as $\langle h|m\rangle$, on which the $sl(2, \mathbb{R})$ generators act from the right with an extra minus sign to get the right commutation relations. In particular, $\langle h|0\rangle$ is indeed an anti-primary state satisfying

$$\langle h|0\rangle(-L_{-1}) = 0, \quad \langle h|0\rangle(-L_0) = (-h)\langle h|0\rangle.$$

(3.33)
Let us also comment on the cases which were excluded above, built on a lowest weight state with negative half-integer weight or a highest weight state with positive half-integer weight. In this case we obtain a finite-dimensional irreducible representation\(^4\) of dimension \(2|\hbar| + 1\), which contains both a highest weight \(|\hbar|\) and a lowest weight \(-|\hbar|\) state. The quadratic Casimir takes the value \(C_2 = |\hbar|(|\hbar| + 1)\). These representations, with the exception of the singlet \(\hbar = 0\), are non-unitary, and will be denoted by \(\mathcal{D}(|\hbar|)\). They are analytic continuations of the unitary finite-dimensional spin \(|\hbar|\) representations of \(su(2)\) and we will therefore also refer to them as ‘spin \(|\hbar|\)’ representations.

We are now ready to work out the particle representations of AdS\(_3\) in the \(\mathfrak{sl}(2, \mathbb{R}) \oplus \mathfrak{sl}(2, \mathbb{R})\) basis. Recall from the previous section that particle representations of \(so(2, 2)\) are labelled as \(D(\Delta, \eta)\) where \(\Delta\) is the energy (eigenvalue of \(P_0 = L_0 + \bar{L}_0\)) and \(\eta\) the helicity (eigenvalue of \(M_0 = L_0 + \bar{L}_0\)) of the lowest energy state in the multiplet. From the above considerations, we see that in the \(\mathfrak{sl}(2, \mathbb{R}) \oplus \mathfrak{sl}(2, \mathbb{R})\) basis these are identified\(^5\) as

\[ D(\Delta, \eta) = (D_+(\hbar), D_-(\bar{\hbar})) \]  

(3.34)

where

\[ \Delta = \hbar + \bar{\hbar}, \quad \eta = \hbar - \bar{\hbar}. \]  

(3.35)

The case where either \(\hbar\) or \(\bar{\hbar}\) vanishes describes a short multiplet and corresponds to a massless higher spin particle. We leave the more challenging problem of relating our description of the massless case to the standard Fronsdal equations for future work, and focus here instead on the case where both \(\hbar, \bar{\hbar} > 0\), which corresponds to massive higher spin fields. The periodicity of the global angular coordinate furthermore restricts the helicity \(\eta\) to be integer (for bosons) or half-integer (for fermions), i.e.

\[ \hbar - \bar{\hbar} \in \mathbb{Z}/2. \]  

(3.36)

Adopting the notation where the vectors in \(D_-(\bar{\hbar})\) are bra states as discussed above, orthonormal basis states of \((D_+(\hbar), D_-(\bar{\hbar}))\) can be represented as ket-bra states of the form

\[ |m\rangle_{\hbar} \langle n|, \quad m, n \in \mathbb{N}. \]  

(3.37)

These are orthogonal with respect to the inner product

\[ (\psi, \psi') = \text{tr} \psi^\dagger \psi' \]  

(3.38)

where the trace is taken in the \(D_+^\hbar\) Hilbert space. Note that the states in particle representations can be interpreted as linear maps (or intertwiners) of \(\mathfrak{sl}(2, \mathbb{R})\) representation spaces

\[ D_+^\hbar \rightarrow D_+^\hbar. \]  

(3.39)

\(^4\) Note that in our representations \(D_+(\hbar)\) and \(D_-(\hbar)\), the generators are manifestly unitarily represented, i.e. \(L_m = L_{-m}\). This has the advantage that, when taking the limit where \(\hbar\) becomes a negative half-integer, no null states appear. This fact will simplify some parts of the subsequent analysis, in particular the results derived in Appendix B.

\(^5\) A different convention, which often appears in the literature, is related to ours by the redefinition \(L_m = L_{-m}\), which preserves the algebra. In this convention, the particle representations are of the (primary, primary) type \((D_+(\hbar), D_-(\bar{\hbar}))\), though \(\mathfrak{sl}(2, \mathbb{R}) \oplus \mathfrak{sl}(2, \mathbb{R})\) is embedded differently into \(so(2, 2)\), i.e. \(P_m = L_m + L_{-m}, M_m = L_m - L_{-m}\).
3.3 Topologically Massive Equations

Before studying our unfolded equations in more detail, it will be useful to recall a peculiarity of massive higher spin equations in AdS$_3$ which was anticipated in Footnote 3. In spacetime dimension three, the subgroup of spatial rotations reduces to SO(2), and the corresponding quantum number is the helicity $\eta = h - \hat{h}$ in (3.35). Since parity changes the sign of $\eta$, the particle representation $(D_+(h), D_-(\hat{h}))$, while furnishing a representation of the component of SO(2, 2) connected to identity, is therefore not invariant under parity. The Fierz-Pauli equations (1.1) in AdS$_3$, which don’t depend on the sign of $\eta$ and are parity-invariant, actually describe the direct sum

$$(D_+(h), D_-(\hat{h})) \oplus (D_+(\hat{h}), D_-(h))$$

The free equations which instead describe only a single helicity $(D_+(h), D_-(\hat{h}))$ (and are necessarily parity non-invariant for $\eta \neq 0$) are generalizations of the topologically massive equations for spin one and two [28]. It will facilitate our discussion in Section 3.6 below to rederive these equations here from a purely group-theoretic point of view.

We start from a field transforming in the spin-$s$ representation, the so-called Lie-Lorentz derivative (see [33] and Appendix A)

$$\mathcal{L}_m \phi_{\alpha_1...\alpha_{2s}}^{(s)} = \frac{i}{\eta} \left( \nabla_\mu \phi_{\alpha_1...\alpha_{2s}}^{(s)} - s e_\mu^n (\gamma_n)_{(\alpha_1}^{(s)} \phi_{|\beta|\beta|\alpha_2...\alpha_{2s})}^{(s)} \right),$$

$$\mathcal{L}_m \phi_{\bar{\alpha}_1...\bar{\alpha}_{2s}}^{(s)} = \frac{i}{\eta} \left( \nabla_\mu \phi_{\bar{\alpha}_1...\bar{\alpha}_{2s}}^{(s)} + s e_\mu^n (\gamma_n)_{(\alpha_1}^{(s)} \phi_{|\bar{\beta}|\bar{\beta}|\bar{\alpha}_2...\bar{\alpha}_{2s})}^{(s)} \right).$$

In the $(D_+(h), D_-(\hat{h}))$ representation, the sl(2, $\mathbb{R}$) and sl(2, $\mathbb{R}$) Casimirs are equal to $h(h - 1)$ and $\hat{h}(\hat{h} - 1)$ respectively. Therefore we impose the following field equations:

$$(\eta^{mn} \mathcal{L}_m \mathcal{L}_n - h(h - 1)) \phi_{\alpha_1...\alpha_{2s}}^{(s)} = 0, \quad (\eta^{mn} \mathcal{L}_m \mathcal{L}_n - \hat{h}(\hat{h} - 1)) \phi_{\bar{\alpha}_1...\bar{\alpha}_{2s}}^{(s)} = 0. \quad (3.42)$$

Using the identities (3.14) for the Killing vectors $\mu_m, \bar{\mu}_m$, these can be rewritten as

$$\left( \nabla_\mu \nabla_\mu - M^2 \right) \phi_{\alpha_1...\alpha_{2s}}^{(s)} = 0, \quad (3.43)$$

$$\nabla_{(\alpha_1} \phi_{|\beta|\beta|\alpha_2...\alpha_{2s})}^{(s)} + \mu \phi_{(s)}^{(s)}_{\alpha_1...\alpha_{2s}} = 0, \quad (3.44)$$

where

$$M^2 = \Delta(\Delta - 2) - s, \quad \mu = \text{sgn}(\Delta - 1). \quad (3.45)$$

We note that for integer spin the first equation (3.43) is the first equation in the Fierz-Pauli system (1.1) in the spinor basis.

For the spin-0 case, the second equation (3.44) is actually absent. For $s \neq 0$, the (3.43, 3.44) equations can be significantly simplified as follows. It is convenient to introduce an operator $D$ which acts on a general multispinor $\tau_{\alpha_1...\alpha_{2s}}$ as

$$(D \tau)_{\alpha_1...\alpha_{2s}} \equiv \nabla_\alpha \tau_{\beta...\alpha_{2s}}.$$
We should note that, when acting with $D$ on a symmetric multispinor the result is in general no longer symmetric, although the square $D^2$ does map symmetric tensors into each other. Indeed, one can show using (A.9) that

$$(D^2 \phi^{(s)})_{\alpha_1...\alpha_{2s}} = (\Box + s + 1)\phi_{\alpha_1...\alpha_{2s}}.$$  (3.47)

Equation (3.44) can be rewritten as

$$2s \mu \phi^{(s)}_{\alpha_1...\alpha_{2s}} = (D\phi^{(s)})_{\alpha_1\alpha_2...\alpha_{2s}} + (D\phi^{(s)})_{\alpha_2\alpha_1...\alpha_{2s}} + \ldots + (D\phi^{(s)})_{\alpha_{2s}\alpha_2...\alpha_{1}}.$$  (3.48)

Acting with $D$ on both sides of this equation, the right-hand side is symmetric due to (3.47), which allows us to derive the integrability condition

$$\nabla_{[\alpha_1} \phi^{(s)}_{\beta_2]} \ldots \phi^{(s)}_{\alpha_{2s}] = 0.$$  (3.49)

This means that the symmetrization in equation (3.44) can be dropped and we can replace it with

$$(D\phi^{(s)})_{\alpha_1...\alpha_{2s}} + \mu \phi^{(s)}_{\alpha_1...\alpha_{2s}} = 0.$$  (3.50)

These equations replace the full system (3.43, 3.44) for $s \neq 0$, since they also imply the Klein-Gordon equation (3.43): using (3.47) we can write

$$(\nabla^\mu \nabla_\mu - M^2) \phi^{(s)}_{\alpha_1...\alpha_{2s}} = (D - \mu)(D + \mu) \phi^{(s)}_{\alpha_1...\alpha_{2s}}.$$  (3.51)

Furthermore, by contracting two indices in (3.50), we see that they imply the divergence-free condition

$$\nabla^{\beta_1 \beta_2} \phi^{(s)}_{\beta_1 \beta_2 \alpha_3...\alpha_{2s}} = 0.$$  (3.52)

which for integer spin is precisely the second Fierz-Pauli constraint in (1.1). The equations (3.50) therefore imply the Fierz-Pauli equations (1.1) (and their generalization for half-integer spin), while it follows from (3.51) that the parity-invariant Fierz-Pauli system describes a pair of topologically massive fields $\phi^{(s)}$, $\tilde{\phi}^{(s)}$ which satisfy (3.50) with opposite signs of $\mu$, and are exchanged by parity. The equations (3.50) are arbitrary spin generalizations [29],[30] of the linearized topologically massive spin-1 and spin-2 equations [28], and are sometimes referred to as self-dual equations. It can be shown [31] that they indeed contain the representation $D(h + \bar{h}, h - \bar{h})$.

### 3.4 Unfolded Massive Equations

After these preliminaries, let us describe in more detail our unfolded equations (2.11) in AdS3. Our unfolded master field $C$ is a zero-form taking values in the internal space $(D_+(h), D_-(h))$, and can be expanded in components in the ket-bra basis (3.37) as follows

$$C = \sum_{m,n \in \mathbb{N}} C_{mn}(x)|m\rangle_h \langle \bar{n}|.$$  (3.53)

The inner product (2.17) on the space of solutions becomes

$$(C, C') = \text{tr} C^\dagger(x)C'(x).$$  (3.54)
In terms of the coefficients (3.53), the inner product equals \( \sum_{mn} \overline{C}_{mn}(x) C'_{mn}(x) \), and it is actually independent of \( x \) as argued below (2.17).

We recall that in the basis (3.53), the generators of \( sl(2, \mathbb{R}) \) act on \( C \) as the operators \( L_m \) in the \( h \)-primary representation (see (3.30)) from the left, while the generators of \( \overline{sl}(2, \mathbb{R}) \) act as the operators \( -L_m \) in the \( \overline{h} \)-primary representation from the right. In other words, the AdS translations and Lorentz generators act as anticommutators and commutators respectively

\[
P_mC = L_mC + CL_m, \quad M_mC = L_mC - CL_m.
\]

The unfolded equations (2.14) read

\[
\nabla C + e^m P_mC = 0,
\]

where the Lorentz covariant derivative acts as

\[
\nabla C = (d + \omega^m M_m) C.
\]

It is sometime useful to write (3.56) in tangent space indices as

\[
(\nabla_m + P_m) C = 0.
\]

We also note that, in terms of the gauge potentials \( A = A^m L_m \) and \( \bar{A} = \bar{A}^m L_m \) (see (3.10), the equations take a form similar to Vasiliev's unfolded equation for the zero form [8]

\[
dC + AC - C\bar{A} = 0,
\]

although, as we already stressed in the Introduction and will explain in detail below, their group-theoretic content is rather different.

The equations of motion are invariant under the \( sl(2, \mathbb{R}) \oplus \overline{sl}(2, \mathbb{R}) \) symmetries of the AdS background which act on the fields as, using (2.21,3.13),

\[
\delta l_mC = l^\mu_m (\nabla_\mu - e^\mu_m M_m) C, \quad \delta \bar{l}_m C = \bar{l}^\mu_m (\nabla_\mu + e^\mu_m M_m) C.
\]

We note that, just like the topologically massive equation (3.50), our unfolded equation is not parity-invariant. Indeed, the natural action of parity on the background gauge fields \( A \) is, in Poincaré coordinates \((t, x, \rho)\),

\[
P : \quad A^m_t(t, x, \rho) \rightarrow \bar{A}^m_t(t, -x, \rho)
\]

\[
A^m_x(t, x, \rho) \rightarrow -\bar{A}^m_x(t, -x, \rho)
\]

\[
A^m_\rho(t, x, \rho) \rightarrow \bar{A}^m_\rho(t, -x, \rho)
\]

and similarly for \( \bar{A} \), so that \( P^2 = 1 \). One can check that this leaves the gravitational action \( S_{CS}[A] - S_{CS}[\bar{A}] \) invariant, where \( S_{CS}[A] \) is the Chern-Simons action. There is no natural transformation law on \( C \) which makes the equation (3.59) invariant under parity. Instead, we can introduce a second field \( \tilde{C} \), taking values in \((D_+(\bar{h}), D_-(h))\), with equation of motion

\[
d\tilde{C} + \bar{A} \tilde{C} - \tilde{C} A = 0.
\]
The combined system (3.59,3.62) is then invariant under the parity transformation
\[ C(t, x, \rho) \rightarrow \tilde{C}(t, -x, \rho) \] (3.63)
and similarly for \( \tilde{C} \). The combined system can also be shown to be time-reversal invariant.

To make matters a little more concrete, we can explicitly work out some of the equations in Poincaré coordinates. The equations of motion (3.59) read:
\[ \partial_\rho C + L_0 C + CL_0 = 0, \quad \partial_+ C + e^\rho L_1 C = 0, \quad \partial_- C - e^\rho C L_{-1} = 0. \] (3.64)
Using (2.16), we can also find the general solution to (3.59). A basis of solutions \( \{ C[pq] \}_{p,q} \) is labelled by two natural numbers \( p, q \) and obtained by applying the gauge transformation (2.16) on constant basis vectors \( |p\rangle \bar{h} \langle q| \) of \( (D_h, D_{\bar{h}}) \). One finds
\[ C[pq](x) = g^{-1}(x)|p\rangle_h \bar{h}\langle q| \tilde{g}(x) = e^{-\rho(h+\hbar+p+q)} \sum_{j=0}^{p} \sum_{k=0}^{q} \mathcal{N}_{j,k}^p q e^{\rho(j+k)} x^j \bar{x}^k |p-j\rangle_h \bar{h}\langle q-k|, \] (3.65)
where
\[ \mathcal{N}_{j,k}^p q = (-1)^j \binom{p}{j} \binom{q}{k} \binom{2h+q-1}{k}. \] (3.66)
For later reference, let us stress that the solutions (3.65) only have a finite number of non-vanishing components. These solutions are by construction orthonormal with respect to the inner product (3.54):
\[ (C[pq], C[q'q']) = \delta_{pp'} \delta_{qq'}. \] (3.67)

3.5 Projecting on Lorentz Tensors

In this and the following subsection, we show how our unfolded equations (2.11) are related to other field theory realizations describing the same massive higher spin particle, namely the topologically massive equations (3.50) and the alternative unfolded description of [14]. Concretely, we will show that both the topologically massive fields and the unfolded fields of [14] can be constructed as linear combinations of our components fields \( C_{mn}(x) \). The construction relies on interesting group-theoretic properties which allow us to project our field \( C \) on an irreducible spin-\( s \) Lorentz tensor, yielding the topologically massive equations, or on the \( so(2,2) \) representation which underlies the unfolded formulation of [14].

To illustrate a crucial difference between our unfolded equations and the standard wave equations, it is instructive to compute the result of acting with the covariant Laplacian on solutions of our unfolded equations. Using the fact that, on \( (D_+(h), D_-(\bar{h})) \), we have the Casimir identity
\[ \eta^{mn} P_m P_n + \eta^{mn} M_m M_n = \eta^{mn} L_m L_n + \eta^{mn} L_m \bar{L}_n = 2h(h-1) + 2\bar{h}(\bar{h}-1). \] (3.68)
we compute, using the equation of motion (3.56) for \( C \),
\[ \nabla_\mu \nabla^\mu C = \eta^{mn} P_m P_n C = (2h(h-1) + 2\bar{h}(\bar{h}-1) - \eta^{mn} M_m M_n) C \] (3.69)
The last term in the brackets is the Casimir operator of the Lorentz subalgebra, which does not evaluate to a constant since our field \( C \) transforms in the reducible representation \( \mathcal{D}_+ (h) \otimes \mathcal{D}_- (\bar{h}) \) under the Lorentz subalgebra; therefore no component of \( C \) itself satisfies a covariant wave equation, in contrast to the standard unfolded formulation [8],[9],[14].

To make contact with covariant wave equations such as the topologically massive equation (3.50), we should therefore project our master field \( C \) onto a field \( \phi^{(s)} \) transforming in the finite-dimensional representation \( \mathcal{D}(s) \), with \( s = |h - \bar{h}| \). In other words, we should construct a covariant linear map or intertwiner between these two Lorentz representations. The existence of such an intertwiner is somewhat nontrivial, as it maps a unitary infinite dimensional representation to a nonunitary finite-dimensional one. It can therefore not be constructed from the known [32] Clebsch-Gordan decomposition of \( \mathcal{D}_+ (h) \otimes \mathcal{D}_- (\bar{h}) \) in terms of unitary representations (which involves members of the continuous series with unbounded energies).

To construct the desired projections we proceed as follows. In Appendix B, we construct vectors in the \((\mathcal{D}_+ (h), \mathcal{D}_- (\bar{h}))\) state space transforming in finite-dimensional representations under the Lorentz subalgebra. We find vectors spanning precisely the spin-t solutions (3.65): each basis solution for \( C \) with \( t \geq s \), \(|a| \leq t \). For \( \bar{h} \geq h \), they are of the form

\[
V_a^{(t)} = \sum_{n \in \mathbb{N}} v_n(t, a) |n\rangle_h \langle n - a - s|,
\]

where the coefficients are given in Appendix B, see (B.10). They transform under the Lorentz subalgebra as

\[
M_m V_a^{(t)} = (mt + a)V_{a-m}^{(t)}.
\]

We should stress at this point that, as shown in Appendix B, the vectors \( V_a^{(t)} \) are not normalizable and are therefore not states in \((\mathcal{D}_+ (h), \mathcal{D}_- (\bar{h}))\) considered as a Hilbert space. However, it is sufficient for our purposes that they have finite overlap with the fields \( C \) which solve the equations of motion (3.56). This can be seen by inspecting the explicit solutions (3.65): each basis solution for \( C \) has only a finite number of nonzero coefficients. Therefore it makes sense to consider the spin-t projections of \( C \) defined as the overlap

\[
\phi_a^{(t)} (x) \equiv \langle V_a^{(t)}, C(x) \rangle.
\]

These indeed transform in a spin-t representation under Lorentz transformations, since from (3.71) we find the intertwining relation

\[
\left( V_a^{(t)}, M_m C(x) \right) = (-mt + a)\phi_a^{(t)} (x) \equiv R^{(t)} (M_m)_a^b \phi_b^{(t)} (x).
\]

One checks that \( R^{(t)} (M_m)_a^b \equiv (-mt + a) \delta_{a+m}^b \) define basis matrices for the spin-t representation \( \mathcal{D}(t) \) of the Lorentz subalgebra.

From (3.73), we can derive a number of useful properties. First of all, the spin-t projection of the Lorentz-covariant derivative \( \nabla C \) is precisely the covariant derivative of \( \phi_a^{(t)} (x) \):

\[
\left( V_a^{(t)}, \nabla C \right) = d\phi_a^{(t)} + \omega^m R^{(t)} (M_m)_a^b \phi_b^{(t)} \equiv \nabla \phi_a^{(t)}.
\]
Furthermore, using (3.60), we find that the spin-$t$ projection of an infinitesimal symmetry transformation acting on $C$ gives precisely the Lie-Lorentz derivative (see (A.19, A.20)) with respect to the corresponding Killing vector:

$$
V^a(t) \delta_{lm} C = \sum_{b,c} \left( \nabla_{\mu} \phi^b(t) - e_{\mu}^{\rho} R^{l(t)}(\rho_p)_a^b \phi^b(t) \right) \equiv C_{lm} \phi^l(t)
$$

$$
V^a(t) \delta_{lm} C = \sum_{b,c} \left( \nabla_{\mu} \phi^b(t) + e_{\mu}^{\rho} R^{l(t)}(\rho_p)_a^b \phi^b(t) \right) \equiv C_{lm} \phi^l(t).
$$

The full set of states $V^a(t)$ for $t \geq s, |a| \leq t$ constructed above have the remarkable property that they form an irreducible representation of the full AdS$_3$ symmetry. To show this one needs to check that they transform among themselves under AdS translations. As shown in Appendix B, this is indeed the case, with

$$
P_m V^a(t) = 2V^{a+1} - \frac{\mu s}{t(t+1)}(mt+a)V^a(t) + \frac{(s^2-t^2)(\mu^2-t^2)}{2t(2t+1)}d_m(t,a)V^{a-1}(t).
$$

where the coefficients $d_m(t,a)$ are given in (B.13). This means that the full set of projections $\phi^a(t)$ for $t \geq s, |a| \leq t$ also form an irreducible multiplet of $sl(2,\mathbb{R}) \oplus sl(2,\mathbb{R})$, with translations acting as

$$
(V^a(t),P_m C) = 2\phi^{a+1} - \frac{\mu s}{t(t+1)}(-mt+a)\phi^a(t) + \frac{(s^2-t^2)(\mu^2-t^2)}{2t(2t+1)}d_m(t,a)\phi^{a-1}(t-1)
\equiv P_m \phi^a(t).
$$

The spin $s = 0$ case, $h = \bar{h}$, deserves a further comment, since the vectors $V^a(t)$ constructed above then possess extra structure related to higher spin algebras. This extra structure arises because in this case, the particle representation $(D_+(h),D_-(h))$ can be viewed as a map from $D_+(h)$ to itself,

$$
D_+^+ \rightarrow D_+^+,
$$

and it makes sense to consider the product or commutator of the $V^a(t)$.

The state of Lorentz spin 0 is simply the identity operator

$$
V_0^{(0)} = \sum_n |n\rangle_{hh}^\langle n| = 1
$$

so that the projection on the Klein-Gordon field is simply $\phi^{(0)} = \text{tr} C$. The spin-1 vectors are simply the $sl(2,\mathbb{R})$ operators $V^{(1)}_m = L_{-m}$ given in (3.30). The lowest weight vector of Lorentz spin $t$ is

$$
V^{(t)}_{-t} = (L_1)^t
$$

and the other $V^{(t)}_{-t}$ are constructed from these using (B.7). By construction, the $V^a(t)$ for $t \neq s$ form a $hs[\lambda]$ algebra under taking commutators, with $\lambda^2 = 4(h(h-1) + 1$, while under operator multiplication we expect recover the ‘lone-star’ product [34]. This structure plays
We convert this to spinor form using the identities
\[ \phi_a^{(s)} \leftrightarrow \phi_{a_1 \ldots a_{2t}}^{(t)} \] (3.82)
where the indices are related as
\[ a = \frac{1}{2} \sum_{i=1}^{2t} \alpha_i, \quad \alpha_1 \ldots \alpha_{2t} = + \ldots + - \ldots - \]
and we should keep in mind that \( \phi_{a_1 \ldots a_{2t}}^{(t)} \) is defined to be totally symmetric.

Under this relabelling, the symmetry under Lie-Lorentz derivatives (3.76) gets converted to their equivalent spinorial expressions (3.41). By construction, the field \( \phi_{a_1 \ldots a_{2s}}^{(s)} \) satisfies the Casimir relations (3.42) and, as shown in Section 3.3, it follows that they also satisfy the topologically massive equations (3.50).

3.6 Recovering the Topologically Massive Equations
Returning to the case of general spin, it is now straightforward to show that our unfolded equations imply the topologically massive equations (3.50). We start by converting the index \( a \) of the fields \( \phi_a^{(s)} \) into a rank-2s symmetric spinor index. In our conventions, this amounts to a simple relabeling of indices, since our spin-\( t \) representation matrices (3.73) are precisely the 2t-th symmetric tensor product of our spin-\( \frac{1}{2} \) matrices. Concretely, we define the fields \( \phi_{a_1 \ldots a_{2t}}^{(t)} \), with \( \alpha_j \in \{ - , + \} \) as

\[ \phi_a^{(t)} \leftrightarrow \phi_{a_1 \ldots a_{2t}}^{(t)} \] (3.82)

and we should keep in mind that \( \phi_{a_1 \ldots a_{2t}}^{(t)} \) is defined to be totally symmetric.

Under this relabelling, the symmetry under Lie-Lorentz derivatives (3.76) gets converted to their equivalent spinorial expressions (3.41). By construction, the field \( \phi_{a_1 \ldots a_{2s}}^{(s)} \) satisfies the Casimir relations (3.42) and, as shown in Section 3.3, it follows that they also satisfy the topologically massive equations (3.50).

3.7 Mapping to the Unfolded System of [14]
We can also show that the full set of fields \( \phi_a^{(t)}(x) \) for \( t \geq s, |a| \leq t \) satisfies the unfolded equations of [14]. To this end, we combine (3.78) with the equation of motion (3.56) to obtain

\[ \nabla_m \phi_a^{(t)} = 2\phi_{a+m}^{(t+1)} - \frac{\mu s}{t(t+1)}(-mt + a)\phi_{a+m}^{(t)} + \frac{(s^2 - t^2)(\mu^2 - t^2)}{2t(2t+1)}d_{-m}(t,a)\phi_{a+m}^{(t-1)}. \] (3.84)

We convert this to spinor form using the identities

\[ \phi_{a+m}^{(t+1)} = \frac{1}{2}(\gamma_m)^{\beta \gamma} \phi_{\beta \gamma a_1 \ldots a_{2t}}^{(t+1)} \] (3.85)
\[ (-mt + a)\phi_{a+m}^{(t)} = t(\gamma_m)^{\beta \gamma} \phi_{\beta \gamma a_2 \ldots a_{2t}}^{(t)} \] (3.86)
\[ d_{-m}(t,a)\phi_{a+m}^{(t-1)} = (\gamma_m)^{\alpha_1 a_2 \ldots a_{2t}} \phi_{\alpha_3 \ldots a_{2t}}^{(t-1)} \] (3.87)

Those works make use of an oscillator realization, which describes the direct sum of two irreducible representations of the symmetry algebra, see [23] for details, and therefore correspond to a pair of unfolded equations in our approach. For example, the case \( \lambda = \frac{1}{2} \) can be described by a single harmonic oscillator, and gives rise to the direct sum \( \{ D_{+}^{(\frac{3}{2})}, D_{-}^{(\frac{3}{2})} \} \).
The relation (3.84) therefore becomes
\[ \nabla_m \phi^{(t)}_{\alpha_1...\alpha_2t} = (\gamma_m)^{\beta\gamma} \phi^{(t+1)}_{\beta\gamma\alpha_1...\alpha_2t} - \frac{\mu s}{(t+1)} (\gamma_m)^{\beta\alpha_1} \phi^{(t)}_{\beta\alpha_2...\alpha_2t} \]
\[ + \frac{(s^2 - t^2)(\mu^2 - t^2)}{2(2t + 1)} (\gamma_m)_{\alpha_1\alpha_2} \phi^{(t-1)}_{\alpha_3...\alpha_2t}. \]  \hspace{1cm} (3.88)

This is, up to convention-dependent normalization factors, precisely the unfolded system of Boulanger et al. in spinor variables, see eq. (2.28) in [14]. As was shown there, we can also use (3.88) to give an alternative and more direct derivation of the topologically massive equations (3.50). Taking (3.88) for \( t = s \) and converting the index \( m \) into a pair of spinor indices using (A.13) we obtain
\[ \nabla_{\alpha\beta} \phi^{(s)}_{\alpha_1...\alpha_2s} = -2\phi^{(s+1)}_{\alpha_1\beta...\alpha_2s} + \frac{\mu s}{s + 1} \left( \epsilon_{\alpha_1} \phi^{(s)}_{\beta_2...\alpha_2s} + \epsilon_{\beta_1} \phi^{(s)}_{\alpha_1...\alpha_2s} \right). \]  \hspace{1cm} (3.89)

Upon contracting the \( \beta \) and \( \alpha_1 \) indices in this expression, we obtain the the linearized topologically massive higher spin equations (3.50).

The fully symmetrized part of equation (3.89) shows that the spin-\( s + 1 \) field \( \phi^{(s+1)}_{\alpha_1...\alpha_2s+2} \) can be obtained by acting with covariant derivatives on the spin-\( s \) field \( \phi^{(s)}_{\alpha_1...\alpha_2s} \). By a similar argument holds the same statement holds for components \( \phi^{(t)}_{\alpha_1...\alpha_2t} \) with \( t > s \); one can convert the spacetime index \( m \) in (3.88) to spinorial indices. The last two terms in this equation will then be proportional to at least one epsilon tensor and therefore drop out upon considering the fully symmetric component of the equation. All the information is therefore contained in the spin-\( s \) field, while the spin \( t > s \) fields are auxiliary.

3.8 Explicit Mode Solutions

Using the projections defined above, we can also give a purely algebraic construction of the mode solutions of the topologically massive gravity equations (3.50). In Poincaré coordinates, we start from the basis of solutions \( \{ C^{pq} \}_{p,q \in \mathbb{N}} \) of (3.65) and work out the projection on a spin-\( s \) tensor (assuming \( \hbar \geq h \)) using (3.72, 3.70) to find
\[ \phi^{(s)}_{a[pq]} \equiv \left( V^{(s)}_a, C^{pq} \right) \]
\[ = e^{(a+s-\Delta)\rho} \sum_{n=0}^{\infty} v_n(s,a) N_{p-n,q+a-s-n} e^{-2n\rho x_+^{p-n} x_-^{q+a-s-n}}, \]  \hspace{1cm} (3.90)

where the normalization factor \( N \) was defined in (3.66) and the explicit expression for \( v_n \) is given in Appendix B, see (B.10).

These solutions form a basis of the topologically massive equations transforming as \((D_+(\hbar), D_-((\hbar))\) under the AdS\(_3\) symmetries. A potential caveat in our reasoning so far was that the spin-\( s \) projections of our solutions might actually vanish; the above expression shows this not to be the case. Indeed, they yield the full multiplet of solutions to the topologically massive equations. For example, for the lowest component \( \phi^{(s)}_{-s} = \phi^{(s)}_{-s...-} \) (3.90) reduces to, up to a normalization factor,
\[ \phi^{(s)}_{-s} \sim e^{-(\hbar + \hbar)\rho} x_+^p x_-^q 2F_1 \left( -p, -q, 2\hbar, -\frac{e^{-2\rho}}{(x_+ x_-)^\rho} \right) \]  \hspace{1cm} (3.91)
This expression is nonvanishing and finite since the hypergeometric function truncates to a polynomial with a finite number of terms. One checks that for $h = \bar{h}$ the physical field satisfies the Klein-Gordon equation with the correct mass term (1.2):

$$\left(\nabla^\mu \nabla_\mu - 4h(h - 1)\right)\phi^{(0)}_0[pq] = 0.$$ (3.92)

4 Outlook

In this work, we have proposed a simple unfolded description of particles in an arbitrary representation of the spacetime symmetry. It is somewhat nontrivial to connect this formulation with the standard covariant wave equations, which requires one to construct an intertwiner between this representation and the appropriate tensor under the Lorentz algebra, which we did explicitly for massive fields of arbitrary spin in AdS$_3$. One could say that in our approach, the problem of unfolding a given relativistic wave equation reduces to the representation theoretic problem of constructing the appropriate intertwiner.

We end by pointing out some open problems and possible generalizations.

- Our construction of the projection on spin-$t$ tensors, using the non-normalizeable vectors $V^{(t)}_a$, was somewhat pedestrian and deserves a more rigorous treatment. This could also elucidate whether our unfolded equation is truly equivalent to the alternative unfolded formulation of [14]: though we found a map from our master field to the one in the formulation of [14], it is not clear if this map is invertible (see Appendix A of [36] for a discussion of this issue in the spin-0 case).

- As we show in Appendix B, it is possible to construct highest weight (for $h > \bar{h}$) or lowest weight (for $h < \bar{h}$) vectors with Lorentz spin lower than $s$ in the representation space $(D_+(h), D_-(\bar{h}))$. These are however not part of an irreducible Lorentz representation, rather they form an indecomposable structure. The meaning of the projection of our unfolded field $C$ on this indecomposable structure is unclear to us, though it is somewhat suggestive of a dual formulation involving gauge fields.

- Our explicit construction for AdS$_3$ could be generalized in various ways. For example, in higher dimensions one might expect to be able to construct an intertwiner between the particle representation $D(\Delta, s)$ and the multiplet that underlies the unfolded massive equations of [13]. It would also be interesting to study the relation between our formulation for massless particles and the Fronsdal equations and their standard unfolded form [5], and to study the partially massless case.

- One of our motivations for studying the current unfolded formulation is that it arises naturally in the AdS$_3$ theory with higher spin square gauge symmetry. In a separate publication [37], we will show that the natural equation describing matter coupled to the higher spin square [23] describes an infinite set of unfolded massive higher spin equations of the type studied in this work.

- Since the present unfolded formulation has a clear group theoretic meaning which involves only the particle representation $D(\Delta, s)$, it may be hoped that it provides
a natural framework to describe higher spin interactions. It would be interesting to give a more group-theoretic characterization of the interaction vertices in Vasiliev theory, especially in their recently developed local form [38], in our framework. It may be also be hoped that the current setup is the natural one for addressing the open problem of constructing the fully interacting theory with higher spin square gauge symmetry.

Acknowledgments

We thank Stefan Fredenhagen, Carlo Iazeolla, Tomáš Procházka, Evgeny Skortsov and Misha Vasiliev for useful discussions. We are indebted to Mitja Ponomarev and Nicolas Boulanger for carefully reading our manuscript. P.K. would like to thank the Albert Einstein Institute for generous support by which his contribution to the present work became possible. The research of J.R. was supported by the Grant Agency of the Czech Republic under the grant 17-22898S.

A AdS$_3$ Conventions

In this appendix, we spell out some of our conventions for AdS$_3$. The AdS$_3$ symmetry algebra is

\[
[M_m, M_n] = \epsilon_{mn}^p M_p, \quad [M_m, P_n] = \epsilon_{mn}^p P_p, \quad [P_m, P_n] = \epsilon_{mn}^p P_p
\]  

(A.1)

where

\[
\eta_{mn} = \begin{pmatrix} 0 & 0 & -2 \\ 0 & 1 & 0 \\ -2 & 0 & 0 \end{pmatrix}, \quad \epsilon_{-0+} \equiv 2.
\]  

(A.2)

In terms of the $sl(2,\mathbb{R}) \oplus \overline{sl(2,\mathbb{R})}$ basis we have $M_m = L_m + \bar{L}_m$, $P_m = L_m - \bar{L}_m$. From the dreibein and spin connection, we can form the AdS$_3$ connection

\[
\mathcal{A} = \epsilon^m P_m + \omega^m M_m
\]  

(A.3)

whose flatness, $d\mathcal{A} + \mathcal{A} \wedge \mathcal{A} = 0$, is equivalent to the structure equations

\[
de^m + \epsilon_{np}^m e^n \wedge \omega^p = 0, \quad d\omega^m + \frac{1}{2} \epsilon_{np}^m (\omega^n \wedge \omega^p + e^n \wedge e^p) = 0.
\]  

(A.4)

Let $\Phi_R$ be a field transforming in a representation $R$ under local Lorentz transformations. The Lorentz covariant derivative is

\[
\nabla_\mu \Phi_R = (\partial_\mu + \omega_\mu^m R(M_m)) \Phi_R.
\]  

(A.5)

where $R(M_m)$ are the representation matrices. For example, on a tangent vector the appropriate representation is

\[
R(M_m) v^n = -\epsilon^n_m v^p.
\]  

(A.6)
The covariant derivative can be extended to tensors with curved indices in the usual way using the Christoffel symbols. The covariant derivative has the following properties

\[ \nabla_{\mu} e^{m}_{\nu} = 0, \]  
\[ \nabla_{\mu} (R(M_{n})\Phi_{R}) = R(M_{n})\nabla_{\mu} \Phi_{R}, \]  
\[ [\nabla_{m}, \nabla_{n}]\Phi_{R} = -\epsilon_{mn}^{\ p} R(M_{p})\Phi_{R}, \]  
where the last identity is derived from (A.4).

We often use spinor notation, with indices \( \alpha, \beta, \ldots \in \{-, +\} \), which are raised and lowered with \( \epsilon_{\alpha\beta} \) and \( \epsilon^{\alpha\beta} \), where \( \epsilon^{-+} = \epsilon^{-+} = 1 \).

We use ‘northwest-southeast’ conventions:

\[ \epsilon^{\alpha\beta} v_{\beta} = v_{\alpha}, \quad v^{\beta} \epsilon_{\beta\alpha} = v_{\alpha}. \]  

The gamma matrices are denoted as \( \gamma_{m}, m \in \{-, 0, +\} \) are given by

\[ (\gamma^{-})_{\alpha}^{\beta} = \begin{pmatrix} 0 & 0 \\ 2 & 0 \end{pmatrix}, \quad (\gamma^{0})_{\alpha}^{\beta} = \begin{pmatrix} -1 & 0 \\ 0 & 1 \end{pmatrix}, \quad (\gamma^{+})_{\alpha}^{\beta} = \begin{pmatrix} 0 & -2 \\ 0 & 0 \end{pmatrix}, \]  

and they satisfy

\[ \gamma_{m} \gamma_{n} = \eta_{mn} + \epsilon_{mn}^{\ p} \gamma_{p}. \]  

The spin-s representation of the Lorentz algebra acts on a rank-2s symmetric multi-spinor as

\[ R_{s}(M_{m})\phi_{a_{1}...a_{2s}} = s(\gamma_{m})_{(a_{1}}^{\beta} \phi|_{a_{2}...a_{2s})}. \]  

In the main text we make use of an operator \( D \) defined as

\[ (D\phi)_{a_{1}...a_{2s}} \equiv \nabla_{a_{1}}^{\beta} \phi_{\beta...a_{2s}} \]  

one can show, using (A.9), that

\[ D^{2}\phi_{a_{1}...a_{2s}} = (\Box + s + 1)\phi_{a_{1}...a_{2s}}. \]  

Note that \( D \) does not map symmetric spinors into symmetric spinors in general, while \( D^{2} \) does.

We also make use of the Lorentz-covariant definition of the Lie derivative with respect to a Killing vector \( k \), acting on fields in arbitrary representations of the Lorentz algebra, see [33]. This definition extends the standard definition of the Lie derivative of tensor fields and is called the Lie-Lorentz derivative. For a field \( \phi_{a} \) transforming in a representation \( R \) under the Lorentz algebra, it is defined as

\[ L_{k}\phi_{a} = k^{\mu}\nabla_{\mu} \phi_{a} + \frac{1}{2} \nabla_{[m} k_{n]} \epsilon^{mnp} R(M_{p})^{b}_{\ a} \phi_{b}. \]
From this definition, using (A.6) and the fact that \( k \) is a Killing vector, one shows that
\[
L_k e^m_\mu = 0, \quad L_k R(M_m)_a^b = 0. \tag{A.18}
\]
On AdS\(_3\), using the identities (3.15), the Lie-Lorentz derivative simplifies to
\[
L_{l_m} \phi_a = l^\mu_m \left( \nabla_\mu \phi_a - e^\mu R(M_p)_a^b \phi_b \right), \tag{A.19}
\]
\[
L_{\bar{l}_m} \phi_a = \bar{l}^\mu_m \left( \nabla_\mu \phi_a + e^\mu R(M_p)_a^b \phi_b \right). \tag{A.20}
\]
In spinor notation, this leads to (3.41).

**B Representations of the Lorentz Subalgebra**

In this appendix, we will construct vectors in the representation space\(^7\) \((\mathcal{D}_+(\bar{h}), \mathcal{D}_-(\bar{h}))\) with \( h, \bar{h} > 0 \) which transform in finite-dimensional representations of the Lorentz subalgebra.

We recall that, in the ket-bra notation introduced in Section 3.2, the Lorentz generators \( M_m \) act on this space as
\[
M_m \psi = L_{l_m} \psi - \psi L_{\bar{l}_m},
\]
with the \( L_{l_m} \) given explicitly in (3.30). We start by constructing all lowest Lorentz weights \( \lambda_w \) and highest weights \( \nu_w \) defined by the properties
\[
M_0 \lambda_w = w \lambda_w, \quad M_1 \lambda_w = 0 \tag{B.1}
\]
\[
M_0 \nu_w = w \nu_w, \quad M_{-1} \nu_w = 0 \tag{B.2}
\]
It follows that if \( \lambda_w \) is a lowest weight \( w \) state, then
\[
\lambda_{w-k} \equiv L_1^k \lambda_w = \left( \frac{P_{1}}{2} \right)^k \lambda_w, \quad k \in \mathbb{N}, \tag{B.3}
\]
if nonvanishing, is another lowest weight state of weight \( w - k \). Similarly if \( \nu_w \) is a highest weight \( w \) state, then
\[
\nu_{w+k} \equiv L_{-1}^\tilde{k} \nu_w = \left( \frac{P_{-1}}{2} \right)^\tilde{k} \nu_w, \quad \tilde{k} \in \mathbb{N}, \tag{B.4}
\]
if nonvanishing, is another highest weight state of weight \( w + \tilde{k} \).

Starting from an ansatz describing the most general vector with fixed Lorentz weight under \( M_0 \), one finds that the full set of lowest (highest) weight vectors can be obtained in this way, through repeated action of \( L_1 \) (\( L_{-1} \)) on a single starting vector.

One finds lowest weight vectors at weights \( -s - k \) and highest weight vectors at weights \( -s + \tilde{k} \), with \( k, \tilde{k} \in \mathbb{N} \) and \( s \equiv |h - \bar{h}| \). Assuming for the moment that \( h \leq \bar{h} \) (we will return to the case \( h > \bar{h} \) below), these vectors are given by
\[
\lambda_{-s-k} = L_1^k \lambda_{-s}, \quad \lambda_{-s} = \sum_{n \in \mathbb{N}} \left( \frac{(2\bar{h} + n - 1)!}{(2h + n - 1)!} \right)^{1/2} |n\rangle_{h \bar{h}} \langle n| \tag{B.5}
\]
\[
\nu_{-s+\tilde{k}} = L_{-1}^\tilde{k} \nu_{-s}, \quad \nu_{-s} = \sum_{n \in \mathbb{N}} \left( \frac{(2\bar{h} + n - 1)!}{(2h + n - 1)!} \right)^{1/2} |n\rangle_{h \bar{h}} \langle n|. \tag{B.6}
\]
\(^7\) Viewed here as the vector space \( \text{Span}\{ |m\rangle_{h \bar{h}} \langle n|, m, n \in \mathbb{N} \} \), in particular we will not insist on normalizeability with respect to the norm (3.54) on \((\mathcal{D}_+(h), \mathcal{D}_-(\bar{h}))\).
Let us now proceed to arrange these highest and lowest weight vectors and their Lorentz descendants into multiplets, see Figure 1 for the resulting weight diagram in the case of spin 2.

Figure 1. Weight diagram showing the highest (in red) and lowest (in green) weight states under the Lorentz algebra and their descendants (in blue), for the spin 2 case with $h - h = 2$. An arrow pointing up (down) means that the states are linked by the action of $M_{-1}$ ($M_1$). We note that the states $\nu_{-1}$ and $\nu_{-2}$ are null primaries. The states in the blue shaded region are the $V_{(t)}^a$ which form an irreducible representation of the full AdS algebra $\mathfrak{sl}(2, \mathbb{R}) \oplus \mathfrak{sl}(2, \mathbb{R})$. Only the states in the green shaded region are actually normalizable.

Setting $\tilde{k} = 2s + k$ in (B.6), we find that $\nu_{s+k} \sim M_{-1}^{2(s+k)}\lambda_{-s-k}$ and hence these vectors are the lowest and highest weights of a $2(s+k) + 1$-dimensional spin-($s+k$) representation, denoted as $\mathcal{D}(s+k)$ in Section 3.2. We will denote the basis vectors in the $\mathcal{D}(t)$ multiplet as $V_{(t)}^a$, with $a$ running from $-t$ to $t$ and normalized as follows:

$$V_{(t)}^a = (-1)^{t+a}(t-a)! \left(2t\right)! M_{-1}^{t+a} (L_{-s}^{t-s} \lambda_{-s}) , \quad t \geq s, |a| \leq t$$

Our normalization constants are chosen such that $V_{-t}^{(t)} = \lambda_{-t}, V_{t}^{(t)} = \nu_{t}$ and such that the Lorentz generators act as

$$M_m V_{(t)}^a = (mt + a) V_{(t)}^{a-m} .$$
For the explicit component expression of the $V_a^{(t)}$ one finds
\[ V_a^{(t)} = \sum_{n \in \mathbb{N}} v_n(h, \bar{h}; t, a) |n\rangle_{h \bar{h}} \langle n-a-s|, \quad \text{for } h \leq \bar{h} \] (B.9)
with (recall $\Delta \equiv h + \bar{h}$)
\[
v_n(h, \bar{h}; t, a) = \frac{(t-a)^{l-a}}{(2t)!} \sum_{l=0}^{t+a} (-1)^l \binom{t+a}{l} \left((1 - 2h - n)_l(-n)_l(1 - l + n)_t(2h - l + n)_t \right)^{1/2},
\]
where $(x)_n = x(x+1) \ldots (x+n-1)$ denotes the Pochhammer symbol. To find similar expressions for the case $h > \bar{h}$, one notes that the Hermitean conjugate $(V_a^{(t)})^\dagger$ is a state of weight $-a$ in the space $(\mathcal{D}_+(\bar{h}), \mathcal{D}_-(h))$, leading to
\[ V_a^{(t)} = \sum_{n \in \mathbb{N}} v_n(h, \bar{h}; t, -a) |n + a - s\rangle_{h \bar{h}} \langle n|, \quad \text{for } h \geq \bar{h} \] (B.11)

As we saw in (B.8), the vectors $V_a^{(t)}$ span the representation $\oplus_{t=s}^{\infty} \mathcal{D}(t)$ under the Lorentz subalgebra generated by $M_m$. What is more, they also transform among themselves under the full $sl(2, \mathbb{R}) \oplus sl(2, \mathbb{R})$ symmetry, under which they form a single irreducible representation. To see this, we have to work out how the AdS translation generators act on them; one can derive the following relation:
\[ P_m V_a^{(t)} = 2V_{a-m}^{(t+1)} - \frac{\mu s}{t(t+1)} (mt + a) V_{a-m}^{(t)} + \frac{(s^2 - t^2)(\mu^2 - t^2)}{2t(2t+1)} d_m(t, a) V_{a-m}^{(t-1)}. \] (B.12)
where $\mu$ was defined in (3.45) and we defined the coefficients
\[ d_{\pm}(t, a) = \frac{(a \pm t)(a \pm (t-1))}{t(2t-1)}, \quad d_0(t, a) = \frac{a^2 - t^2}{t(2t-1)}. \] (B.13)
The coefficients in (B.12) are completely fixed by the properties (B.3,B.4), consistency with the AdS algebra (A.1) and the Casimir relation
\[ \eta^{mn} P_m P_n V_a^{(t)} = (2(h_{-1} + 2\bar{h}) - t(t+1)) V_a^{(t)}. \] (B.14)
We also verified (B.12) using the explicit expressions (B.9).

We also mention a further useful relation involving the action of the translation generators $P_m$ on the vectors $V_a^{(t)}$. Recalling that these act as $P_m \psi = L_m \psi + \psi L_m$ one can derive the following identity
\[ M_{-1}^{n+1} P_1 = n(n+1) P_{-1} M_{-1}^{n-1} - 2(n+1) P_0 M_{-1}^n + P_1 M_{-1}^{n+1}. \] (B.15)
Combining this with (B.7), we find a relation expressing the vectors in the spin-$t + 1$ representation in terms of the action of the translation generators on vectors in the spin-$t$ representation:
\[ V_a^{(t+1)} = \sum_{m=-1}^{1} c_m(t, a) P_m V_a^{(t)} \] (B.16)
where
\[ c_{-1} = \frac{(t + a)(t + a + 1)}{2(2t + 2)(2t + 1)}, \quad c_0 = \frac{(t + a + 1)(t - a + 1)}{(2t + 2)(2t + 1)}, \quad c_1 = \frac{(t - a + 1)(t - a)}{2(2t + 2)(2t + 1)}. \]
(B.17)

In (B.6) we also found, for \( \bar{h} > h \), a number of highest weight vectors, namely \( \nu_{-s+k} \) for \( 0 \leq \bar{k} < 2s \), for which there is no corresponding lowest weight vector and which hence do not fit in finite-dimensional representations. Though these do not play a role in the present work (see however the Outlook section), we now briefly comment on the Lorentz representations carried by these states. One checks that
\[ \nu_{-s+k} \sim M^{{2(s-k)-1}}_{1(2h+\bar{k}+1,2h+\bar{k},2\bar{h},1)}, \quad \text{for } 0 \leq \bar{k} < s - \frac{1}{2}. \]
(B.18)

The \( \nu_{-s+k} \) for \( 0 \leq \bar{k} < s - \frac{1}{2} \) and their descendants therefore form an invariant subspace whose complement is not invariant; in that case \( \nu_{-s+k} \) and \( \nu_{s-\bar{k}-1} \) belong to an infinite-dimensional reducible but indecomposable representation of the Lorentz subalgebra.

Let us also discuss the normalizability of the vectors constructed above with respect to the inner product (3.54). One finds that the norm of the highest weight vectors for \( \bar{h} \geq h \) is
\[ |\nu_{-s+k}|^2 = \frac{k!(2h+\bar{k}-1)!}{(2h-1)!} 2F_1(k+1,2h+\bar{k},2\bar{h},1), \quad \text{for } h \leq \bar{h}, \]
(B.19)

Using well-known convergence properties of the hypergeometric function [39], we find that the highest weight states are therefore normalizable for \( \bar{k} < s - \frac{1}{2} \). In other words, only the ‘null’ highest weight vectors discussed above are actually normalizeable8. In particular, the vectors \( V^{(t)}_a \) comprising the finite-dimensional representations are not normalizable.
