Abstract It is proven that for any representation over a field of characteristic 0 of the non-abelian semidirect product of a cyclic group of prime order $p$ and the group of order 3 the corresponding algebra of polynomial invariants is generated by elements of degree at most $p + 2$. We also determine the exact universal degree bound for separating systems of polynomial invariants of this group in characteristic not dividing $3p$.

1 Introduction

A classical theorem of Noether asserts that the ring of polynomial invariants of a finite group $G$ is generated by its elements of degree at most $|G|$, provided that the characteristic of the base field $\mathbb{F}$ does not divide $|G|$ (this was proved in [21] for $\text{char}(\mathbb{F}) = 0$, and the result was extended more recently to non-modular positive characteristic independently by Fleischmann [12] and Fogarty [13]). Denoting by $\beta(\mathbb{F}[V]^G)$ the minimal positive integer $n$ such that the algebra $\mathbb{F}[V]^G$ of polynomial invariants is generated by elements of degree at most $n$, the Noether number is defined as

$$\beta(G) := \sup_V \beta(\mathbb{F}[V]^G)$$

where $V$ ranges over all finite dimensional $G$-modules over $\mathbb{F}$. Throughout the paper we shall assume that $\text{char}(\mathbb{F})$ does not divide $|G|$. For a cyclic group $Z_n$ of order $n$ we have

This paper is based on results from the PhD thesis of the author written at the Central European University.

\[ \beta(Z_n) = n, \text{ but Noether's bound is never sharp for a non-cyclic group, see [3, 8, 23, 24].} \]

These latter works show that an unavoidable step in improving the Noether bound is to find good upper bounds for \( \beta(Z_p \times Z_q) \), where \( Z_p \times Z_q \) is the non-abelian semidirect product of cyclic groups of odd prime order (hence \( q \) divides \( p - 1 \)). The exact value of the Noether number is known only for a few very special series of groups (see [4]) and for a couple of groups of small order. The following conjecture is attributed to \([22]\) in \([26]\):

**Conjecture 1.1** (Pawale) We have \( \beta(Z_p \times Z_q) = p + q - 1 \).

The analogous statement for \( q = 2 \) (i.e. when the group is the dihedral group of order \( 2p \)) is proved in \([23]\) for \( \text{char}(\mathbb{F}) = 0 \) and in \([24]\) for the case when \( \text{char}(\mathbb{F}) \) does not divide \( 2p \). Otherwise the only known case of Conjecture 1.1 is that \( \beta(Z_7 \times Z_3) = 9 \) (this was proved for \( \text{char}(\mathbb{F}) = 0 \) in \([22]\), and an alternative proof extending to non-modular positive characteristic is given in \([3]\)). The inequality \( \beta(Z_p \times Z_q) \geq p + q - 1 \) follows from a more general statement in \([4]\). Explicit upper bounds for \( \beta(Z_p \times Z_q) \) are given in \([3]\); in the special case \( q = 3 \) they yield \( \beta(Z_p \times Z_3) \leq p + 6 \) (this was proved in \([22]\) for \( \text{char}(\mathbb{F}) = 0 \)).

This paper focuses on the non-abelian semidirect product \( G := Z_p \rtimes Z_3 \). Our main result confirms Conjecture 1.1 for this group \( G \) inasmuch as we prove that \( \beta(\mathbb{F}[V]^G) = p + 2 \) holds for \( \text{char}(\mathbb{F}) = 0 \) or for any multiplicity free \( G \)-module \( V \) in non-modular positive characteristic. In fact this is the special case \( k = 1 \) of Theorem 3.4, asserting that \( \beta_k(\mathbb{F}[V]^G) = kp + 2 \) for any positive integer \( k \), where \( \beta_k(\mathbb{F}[V]^G) \) denotes the maximal degree of a homogeneous element of \( \mathbb{F}[V]^G \) not contained in the \((k + 1)\)-st power of the maximal homogeneous ideal \( \mathbb{F}[V]^G \).

As an application of the result on multiplicity free modules we determine the exact value of \( \beta_{\text{sep}}(Z_p \rtimes Z_3) \), the version of the Noether number for *separating invariants*, studied recently in \([18]\). Thanks to a theorem of Draisma et al. \([10]\) on *cheap polarization* (see also \([19]\) and \([17]\)), our study of the multiplicity free \( Z_p \rtimes Z_3 \)-modules will be sufficient to determine the *separating Noether bound* for arbitrary modules, see Theorem 4.1.

### 2 Preliminaries

In the rest of the paper \( G \) will be the non-abelian semidirect product

\[ G := Z_p \rtimes Z_3 = \langle c, d : c^p = d^3 = 1, dcd^{-1} = c^r \rangle \]

where \( r \) has order 3 modulo \( p \) for some prime \( p \) with 3 dividing \( p - 1 \), and \( \mathbb{F} \) is a field of characteristic different from \( p \) or 3. For sake of convenience we shall assume in the text that \( \mathbb{F} \) is algebraically closed. This is relevant for example when we list the irreducible \( G \)-modules. However, the Noether number or the condition that a \( G \)-module is multiplicity free are not sensible for extension of the base field. In particular, the final statements Corollary 3.2, Theorem 3.4, and Theorem 4.1 remain valid without the assumption on algebraic closedness. By a *\( G \)-module* we mean a finite dimensional \( \mathbb{F} \)-vector space endowed with a linear (left) action of \( G \) on \( V \), and write \( \mathbb{F}[V] \) for the coordinate ring of \( V \). This is the symmetric tensor algebra of \( V^* \), the dual space of \( V \) endowed with the natural right action \( x^g(v) := x(gv) \) \((g \in G, v \in V, x \in V^*)\). The corresponding *algebra of polynomial invariants* is

\[ \mathbb{F}[V]^G := \{ f \in \mathbb{F}[V] : f^g = f \quad \forall g \in G \}. \]

Denote by \( A \) the \( p \)-element normal subgroup of \( G \), and \( \hat{A} := \text{hom}_\mathbb{Z}(A, \mathbb{F}^\times) \) the group of characters of \( A \); there is a non-canonic isomorphism between \( \hat{A} \) and \( A \). Denote by \( B \) a 3-element subgroup in \( G \). The conjugation action of \( B \) on \( A \) induces an action on \( \hat{A} \) given
by $\chi^g(a) = \chi(gag^{-1})$, where $\chi \in \hat{A}$, $g \in B$, $a \in A$. The trivial character of $A$ is fixed by all elements in $B$, whereas the remaining characters are partitioned into $l := \frac{p-1}{3}$ $B$-orbits $O_1, \ldots, O_l$ of size 3. Up to isomorphism there are three 1-dimensional $G$-modules, namely the three 1-dimensional $B \cong G/A$-modules lifted to $G$. The remaining irreducible $G$-modules $V_1, \ldots, V_l$ are in a natural bijection with the $l$-element set $\{O_1, \ldots, O_l\}$. Namely the 3-dimensional $G$-module induced from a non-trivial character of $A$ is irreducible, and two such induced $G$-modules are isomorphic if and only if the $A$-characters we started with are in the same $B$-orbit $O_j$. It follows that it is possible to choose a set of variables in the polynomial ring $\mathbb{F}[V]$ such that the variables are $A$-eigenvectors permuted by $G$ up to non-zero scalar multiples, moreover, the $B$-orbit of any variable spans an irreducible $G$-module summand in $V^*$. We shall always assume that our variables in $\mathbb{F}[V]$ satisfy these requirements. Then any monomial $m$ has a weight $\theta(m) \in \hat{A}$ defined by $m^a = \theta(m)(a)m$ for all $a \in A$, and a weight sequence $\Phi(m) := (\theta(x_1), \theta(x_2), \ldots, \theta(x_d))$, where $m = x_1x_2 \ldots x_d$, and $x_1, x_2, \ldots, x_3$ are not necessarily different variables; so $\Phi(m)$ is a sequence over the abelian group $\hat{A}$. We shall write $\hat{A}$ additively.

We need to recall some terminology and facts about zero-sum sequences (see [15,16] as a general reference). By a sequence over an abelian group $C$ (written additively) we mean a sequence $S := (c_1, \ldots, c_n)$ of elements $c_j \in C$ where repetition of elements is allowed and their order is disregarded. The length of $S$ is $|S| := n$. By a subsequence of $S$ we mean $S_J := (c_j \mid j \in J)$ for some subset $J \subseteq \{1, \ldots, n\}$. We write $S = S_1S_2$ if $S$ is the concatenation of its subsequences $S_1$, $S_2$. The set of partial sums of $S$ is $\Sigma(S) := \{\sum_{i \in I} c_i : I \subseteq \{1, \ldots, n\}\}$. We say that $S$ is a zero-sum sequence if $c_1 + \cdots + c_n = 0$. A zero-sum sequence is irreducible if there are no non-empty zero-sum sequences $S_1$ and $S_2$ such that $S = S_1S_2$. Furthermore, $S$ is zero-sum free if it has no non-empty zero-sum subsequence. We call the height of $S$ the maximal multiplicity of an element in $S$. Given an element $c \in C$ and a positive integer $r$, write $(c^r)$ for the sequence of length $r$ in which $c$ occurs with multiplicity $r$. We collect for later reference some facts about zero-sum sequences over the cyclic group $\mathbb{Z}_p$. The Cauchy-Davenport Theorem asserts that for any non-empty subsets $K, L \subseteq \mathbb{Z}_p$

$$|\{k + l \mid k \in K, l \in L\}| \geq \min\{|K|, |L| + 1\}$$

(Vosper’s theorem (see Theorem 5.9. in [25]) states that equality in (2.1) implies that $K$ and $L$ are arithmetic progressions of the same step, provided that $|K|, |L| \geq 2$ and $|K + L| \leq p - 2$. We shall repeatedly use the following easy consequence of the Cauchy-Davenport Theorem and Vosper’s Theorem:

**Lemma 2.1** If $S = (s_1, \ldots, s_d)$ is a sequence of non-zero elements over $\mathbb{Z}_p$ for a prime $p$ then $|\Sigma(S)| \geq \min\{p, d + 1\}$. Moreover if $p - 1 \geq |\Sigma(S)| = d + 1$ then $S = (-a^k, a^{d-k})$ for some $a \in \mathbb{Z}_p \setminus \{0\}$ and $0 \leq k \leq d$.

Zero-sum sequences appear in the study of $\mathbb{F}[V]^G$ because there is a graded $\mathbb{F}[V]^G$-module surjection

$$\tau : \mathbb{F}[V]^A \to \mathbb{F}[V]^G, \quad f \mapsto \sum_{b \in B} f^b,$$

and $\mathbb{F}[V]^A$ is spanned as an $\mathbb{F}$-vector space by the monomials $m$ such that $\Phi(m)$ is a zero-sum sequence over $\hat{A}$. The map $\tau$ is called the relative transfer map (see for example Chapter 1 in [2] for its basic properties).
3 Modules over the group $\mathbb{Z}_p \times \mathbb{Z}_3$

Let $V = V_1 \oplus \cdots \oplus V_n$ be the direct sum of the irreducible $G$-modules $V_i$. This decomposition gives an identification $F[V] = F[V_1] \otimes \cdots \otimes F[V_n]$ and accordingly any monomial $m \in F[V]$ has a canonical factorization $m = m_{V_1} \cdots m_{V_n}$ into monomials $m_{V_i} \in F[V_i]$. We write $\deg_{V_i}(m) := \deg(m_{V_i})$ for each $i = 1, \ldots, n$. Let $R := F[V]^G$ and $I := F[V]^{\Lambda}$. The degree $d$ homogeneous component of the graded algebras $R$, $I$ is denoted by $R_d$, $I_d$ and their maximal homogenous ideals by $R_+$ and $I_+$, which are spanned by all homogeneous components of positive degree. Moreover, $(R_+)^{\leq p}$ stands for the subspace $R_1 \oplus \cdots \oplus R_p$. For any subspaces $K$, $L \subset R$ the $F$-subspace spanned by the set $\{kl \mid k \in K, l \in L\}$ is denoted by $KL$.

**Proposition 3.1** Let $V = V_1 \oplus \cdots \oplus V_n$ where each $V_i$ is a 3-dimensional irreducible $G$-module. If $m \in I$ is a monomial such that $\deg(m) \geq p + 1$ and $\deg_{V_i}(m) \geq 4$ for some $1 \leq i \leq n$ then $m \in I_+(R_+)^{\leq p}$.

**Proof** Let $t$ be the index for which $\deg_{V_i}(m)$ is maximal; then $\deg_{V_i}(m) \geq 4$. Let $F[V_i] = F[x, y, z]$ where the variables $x$, $y$, $z$ are $A$-eigenvectors cyclically permuted by $B$. Note that $xyz$ is a $G$-invariant. For a monomial $m \in F[V]$ let $\lambda(m)$ denote the non-increasing sequence of integers $(\lambda(m)_1, \ldots, \lambda(m)_h)$ where $\lambda(m)_i$ is the number of elements of $A$ which have multiplicity at least $i$ in the weight sequence $\Phi(m)$ (here $h$ is the maximal multiplicity of a weight in $\Phi(m)$). Choose a divisor $w | m_{V_i}$ such that $\deg(w) = 4$ and $\lambda(w)$ is minimal possible with respect to the anti-lexicographic ordering. We have several cases:

(i) If $\lambda(w) = (3, 1)$ then $w$ contains $xyz \in R_3$ hence $m \in I_+ R_3$

(ii) If $\lambda(w) = (2, 2)$, say $w = x^2y^2$ and $-\theta(xy) \in \Sigma(\Phi(m/w))$ then we can find an $A$-invariant monomial $v$ such that $xy | v | m$ and the zero-sum sequence $(\theta(xy))\Phi(v/xy)$ is irreducible. We claim moreover that $\deg(v) \leq p$. For otherwise $\deg(v) = p + 1$ and $\Phi(v/xy) = (c^{p-1})$ where $c = \theta(xy)$. By the maximality of $\deg_{V_i}(m)$ this weight $c$ cannot belong to any irreducible component different from $V_i$. Moreover, by the minimality of $\lambda(w)$ the weight $c$ must coincide with $\theta(x)$ or $\theta(y)$. But then either $\theta(y) = 0$ or $\theta(x) = 0$, respectively, which is a contradiction. Now set $u = m/v$ and observe that $ux(v) \in I_+(R_+)^{\leq p}$ while $m - ux(v) \in I_+ R_3$ by case (i).

(iii) If $\lambda(w) = (2, 2)$, say $w = x^2y^2$ but $-\theta(xy) \notin \Sigma(\Phi(m/w))$; suppose in addition that $S \cap -S \neq \emptyset$ where $S \subseteq \hat{A}$ denotes the set of weights occurring in $\Phi(m/w)$: then $\Phi(m/w)$ contains a subsequence $(s, -s)T$ where $s \in \hat{A} \cong \mathbb{Z}_p$ and $|T| = p - 3$. Given that $|\Sigma(T)| \geq p - 4$ by Lemma 2.1 and $-\theta(xy) \notin \Sigma(T)$, at least one of the weights $-\theta(x)$, $-\theta(y)$, $-\theta(x^2y)$, $-\theta(xy^2)$ must occur in $\Sigma(T)$. Hence $m = uvw$, where $u$, $v$, $w$ are $A$-invariant, $\Phi(v) = (s, -s)$ and $x | w$, $y^2 | u$ by symmetry in $x$ and $y$. Now as $\deg(vw) \leq 2 + |T| + 3 \leq p$ we have the relation

$$3(vw - v^8w^8) = (v - v^8)\tau(w) + (w - w^8)\tau(v) + \tau(vw - vw^8) \in I(R_+)^{\leq p}$$

whence $uvw - uv^8w^8 \in I_+(R_+)^{\leq p}$ holds, while $uv^8w^8$ falls under case (i).

(iv) If $\lambda(w) = (2, 2)$, say $w = x^2y^2$, $-\theta(xy) \notin \Sigma(\Phi(m/w))$ and $S \cap -S = \emptyset$; then $|\Sigma(\Phi(m/w))| \leq p - 1$ so that $|\Phi(m/w)| \in \{p - 3, p - 2\}$ by Lemma 2.1 and the assumption on $\deg(m)$. As $S \cap -S = \emptyset$ we can apply Balandraud’s theorem (see Theorem 8 in [1]) stating that $|\Sigma(\Phi(m/w))| \geq 1 + v_1 + 2v_2 + \cdots + kv_k$ where $v_1 \geq \cdots \geq v_k$ are the multiplicities of the different elements of $A$ occurring in $\Phi(m/w)$. Given that $|\Sigma(\Phi(m/w))| \leq p - 1$ this forces that $\Phi(m/w)$ must have one the following three forms for some elements $a, b \in \hat{A} \cong \mathbb{Z}_p$:
\[ (a^{p-2}, a^{p-3}, a^{p-4}, b). \]

By the maximality of \( \deg_{\lambda}(m) \) it is evident that \( a \in \{\theta(x), \theta(y)\} \) except if \( p = 7 \) and \( |\Phi(m/w)| = 4 \). But this also holds in this latter case, too, otherwise if \( a \notin \{\theta(x), \theta(y)\} \) then, as \( \hat{A} \setminus \{0\} \) consist only of two \( B \)-orbits for \( p = 7 \) and \( S \cap -S = 0 \) by assumption, it is necessary that \( a = -\theta(z) = \theta(xy) \); hence \( \Phi(m) \) is a zero-sum sequence this rules out the possibility \( \Phi(m/w) = (a^4) \), so it remains that \( \Phi(m/w) = (a^3, b) \) where by the same reason we must have \( b = -5a = -20(z) \); given that a generator \( g \) of \( B \) operates on \( \hat{A} \) by multiplication with 2, this implies that \( b \in \{-\theta(x), -\theta(y)\} \), a contradiction. So from now on we may suppose that \( a = \theta(x) \) (since the case \( a = \theta(y) \) is similar).

(a) If \( \Phi(m/w) = a^{p-2} \) then \( \Phi(m) = (a^p, \theta(y)^2) \) and as \( \Phi(m) \) is a zero-sum sequence it follows that \( \theta(y) = 0 \), a contradiction.

(b) If \( \Phi(m/w) = a^{p-3} \) then \( \Phi(m) = (a^{p-1}, (ra)^2) \) is a zero-sum sequence, where \( r \) has order 3 modulo \( p \). Consequently \( -a + 2ra = 0 \) whence \( 2r \equiv 1 \) modulo \( p \). Given that \( a^3 \equiv 1 \) modulo \( p \) it follows that \( p = 7 \), and \( r = 4 \). Then \( m = uv \), where \( \Phi(u) = \Phi(v) = (a^3, 4a) \), hence \( u \tau(v) \in I_4 R_4 \) and all monomials of \( u \tau(v) - m \) fall under case (i), hence belong to \( I_4 R_3 \).

(c) If \( \Phi(m/w) = (a^{p-4}, b) \) then \( a \neq \theta(xy) \) as \( \theta(y) \neq 0 \), thus the sequence \( S := (a^{p-4}, b, \theta(xy)) \) has height \( h(S) = p - 4 \). Therefore a nonempty zero-sum sequence \( T \subseteq S \) exists; for otherwise if \( S \) were zero-sum free then by a result of Freeze and Smith [14] we have \( |\Sigma(S)| \geq 2|S| - h(S) + 1 = p + 1 \), a contradiction. Moreover \( T \) cannot contain \( \theta(xy) \) since we assumed that \( -\theta(xy) \notin \Sigma(\Phi(m/w)) \). It follows that \( T = (a^j, b) \) for some \( 0 \leq j \leq p-4 \). Here \( j \neq 0 \) since \( b \neq 0 \). Similarly \( j \neq p-4 \), for otherwise \( \theta(x^2 y^2) = 0 \) whence \( \theta(x) = -\theta(y) \) follows, in contradiction with the fact that the variables \( x \) and \( y \) belong to the same representation \( V_t \). This way we obtained a factorization \( m = uv \) where \( \Phi(v) = T \) and \( u \tau(v) \in I_4(R_+)_{\leq p-4} \) while in the same time \( m - u \tau(v) \in I_4 R_3 + I_4(R_+)_{\leq p} \) by case (ii) or (i).

(v) If \( \lambda(w) = (2, 1, 1) \), say \( w = x^3 y \): Here \( \theta(x^2 y) \neq \theta(x) \), for otherwise \( \theta(x) = -\theta(y) \), a contradiction as above. Moreover \( \theta(xy) \) is different from both \( \theta(x^2 y) \) and \( \theta(x) \), for otherwise \( \theta(x) = 0 \) or \( \theta(y) = 0 \). Now we have two cases:

(a) If \( \Sigma(\Phi(m/w)) \) contains \( -\theta(x^2 y) \) or \( -\theta(x) \) then we get an \( A \)-invariant factorization \( m = uv \) such that \( x^2 y \mid u \) and \( x \mid v \). Here we can assure in addition that \( v \) is irreducible, so that \( \deg(v) \leq p \). Then \( u \tau(v) \in I_4(R_+)_{\leq p} \) while the monomials occurring in \( m - u \tau(v) \) both fall under case (i)–(iv), and we are done.

(b) If however \( -\theta(x), -\theta(x^2) \notin \Sigma(\Phi(m/w)) \) then \( |\Sigma(\Phi(m/w))| \leq p - 2 \) while \( |\Phi(m/w)| \geq p - 3 \) by assumption. In view of Lemma 2.1 this situation is only possible if \( |\Phi(m/w)| = p - 3 \) and \( |\Sigma(\Phi(m/w))| = p - 2 \), so that \( \Phi(m/w) = ((-a)^i, a^{p-3-i}) \) for some \( a \in \hat{A} \setminus \{0\} \) and \( 0 \leq i \leq p - 3 \). It is also necessary that \( -\theta(xy) \notin \Sigma(\Phi(m/w)) \), so a factorization \( m = uv \) exists where \( u, v \) are \( A \)-invariant monomials, \( x^2 \mid u, xy \mid v \). Clearly \( u \neq x^2, v \neq xy \), and \( \deg(v) \leq p \). Therefore \( u \tau(v) \in I_4(R_+)_{\leq p} \) and one of the monomials in \( m - u \tau(v) \), say \( uv^8 \) falls under case (i) while the other one, \( m' := uv^8 \) falls under case (v/a), as here \( w' := x^3 z \) and \( \Phi(m'/w') \) does not consist of at most two weights which are negatives of each other.

(vi) \( \lambda(w) = (1, 1, 1, 1) \), say \( w = x^4 \): then \( |\Sigma(\Phi(m/x^2))| = p \) by Lemma 2.1, so that \( -\theta(x) \in \Phi(m/x^2) \) and this gives us then an \( A \)-invariant factorization \( m = uv \) such that
Corollary 3.2 Let \( V = V_1 \oplus \cdots \oplus V_l \) be the direct sum of all pairwise non-isomorphic 3-dimensional irreducible \( G \)-modules, where \( l = \frac{p-1}{3} \). Then \( \mathbb{F}[V]^A \) as a module over \( \mathbb{F}[V]^G \) is generated by elements of degree at most \( p \).

Proof For any monomial \( m \in \mathbb{F}[V]^A \) of degree \( \deg(m) \geq p+1 \) there must be an index \( 1 \leq t \leq l \) such that \( \deg_{V_t}(m) \geq 4 \), hence Proposition 3.1 applies.

We turn now to the \( G \)-module \( V \oplus^2 \), where \( V \) is as in Corollary 3.2. First of all we fix a direct sum decomposition

\[ V \oplus^2 = U_1 \oplus \cdots \oplus U_l \quad \text{where} \quad U_i = V_{i,1} \oplus V_{i,2} \cong V_i \oplus^2 \quad \text{for all} \quad i = 1, \ldots, l \quad (3.1) \]

Extending our previous conventions, the set of variables in the ring \( \mathbb{F}[V \oplus^2] \) is the union of the \( A \)-eigenbases of each \( V^a_{i,j} \) permuted cyclically by \( B \); the divisors \( m_{V_{i,j}} \in \mathbb{F}[V_{i,j}] \) of a monomial \( m \in \mathbb{F}[V \oplus^2] \) are defined accordingly. Finally, the indices \( i \) will be chosen for convenience in such a way that the \( A \)-weights occurring in \( U_i \) and \( U_{i-1} \) are the negatives of each other for each \( i = 1, \ldots, l/2 \).

Proposition 3.3 Let \( I := \mathbb{F}[V \oplus^2]^A \) and \( R := \mathbb{F}[V \oplus^2]^G \). For any monomial \( m \in I \) with \( \deg(m) \geq p+1 \) it holds that \( m \in I_2 I_2^2 + I_+ (R_+) \leq p \), except if \( p = 7 \) and \( \Phi(m) = (a^6, 3a, 5a) \) for some \( a \in \mathbb{Z}_p \setminus \{0\} \).

Proof If \( \deg_{V_{i,j}}(m) \geq 4 \) for any \( i = 1, \ldots, l \) and \( j = 1, 2 \) then \( m \in I_+ (R_+) \leq p \) holds by Proposition 3.1. So for the rest we may suppose that \( \deg_{V_{i,j}}(m) \leq 3 \) for each \( i, j \), hence \( \deg_U(m) \leq 6 \) for each \( i \). On the other hand \( \deg_{U_i \oplus U_{i-1}}(m) \geq 7 \) for some \( t = 1, \ldots, p-1 \) because \( \deg(m) \geq p+1 \). As a result \( \deg_{U_t}(m) \geq 1 \) and \( \deg_{U_{t-1}}(m) \geq 1 \), hence by symmetry, we may suppose that \( m_{V_{i,1}} \) and \( m_{V_{i-1,1}} \) are both non-constant monomials. Here we have three cases:

(i) if \( m \in I_2 w \) for a monomial \( w \in I_{\geq p-1} \) then by assumption \( \deg_{V_{i,j}}(w) \leq 3 \) must hold for each \( i, j \), too. We claim that in this case \( w \in I_2^2 \). For otherwise \( \Phi(w) \) is an irreducible zero-sum sequence of length at least \( p-1 \), hence it is easily seen e.g. using Balandraud’s above mentioned theorem that it must be of the form \( (a^p) \) or \( (a^{p-2}, 2a) \) for some \( a \in \mathbb{Z}_p \setminus \{0\} \). Denoting by \( s \) the index for which the weight \( a \) belongs to the isotypic component \( U_s \), we will have \( \deg_{U_s}(w) \geq p - 2 \geq 7 \), a contradiction, provided that \( p > 7 \). If however \( p = 7 \) then observe that 2 has order 3 modulo 7, hence the weight \( 2a \) belongs to the same component \( U_s \), and since \( m \in I_2 w \) we get \( \deg_{U_t}(m) = \deg_{U_t}(w) + 1 \geq 7 \), a contradiction again.

(ii) if \( m \notin I_2 I_+ \) and \( \Phi(m_{U_{i,t}}) \) contains two different weights (or \( \Phi(m_{U_{i-1,t}}) \) does so, which is a similar case) then take divisors \( u_0 | m_{U_{i,t}} \) and \( v_0 | m_{U_{i-1,t}} \) such that \( \deg(v_0) = 1 \), \( \deg(u_0) = 2 \) and \( \Phi(u_0) \) contains two different weights, too. Set \( w := m/u_0 v_0 \); now, if \( -\theta(v_0) \in \sum(\Phi(w)) \) then \( m = uv \) for some monomials \( u \in I_+ \) and \( v \in (I_+) \leq p \) such that \( u_0 | u \) and \( v_0 | v \) hence the monomials occurring in \( m - ut(v) \) already fall under case (i). Otherwise if \( -\theta(v_0) \notin \sum(\Phi(w)) \) then \( |\sum(\Phi(w))| \leq p - 1 \) while \( |\Phi(w)| \geq p - 2 \) which is only possible by Lemma 2.1 if \( \Phi(w) = (-a^k, a^{p-2-k}) \) for some \( a \in \mathbb{Z}_p \setminus \{0\} \) and \( 0 \leq k \leq p - 2 \). But here we must have \( k = 0 \) (or \( k = p - 2 \) as otherwise we would get back to case (i)). Then for the isotypic component \( U_s \) to which the weight \( a \) belongs we get \( \deg_{U_s}(w) \geq p - 2 \geq 7 \), a contradiction as before, provided
that $p > 7$. For $p = 7$ we get the same contradiction if $a \in \Phi(u_0)$, so it remains that $a = \theta(v_0)$, and therefore $\Phi(m) = (a^6, 5a, 3a)$.

(iii) if $m \notin I_2 I_3$ and $\Phi(m_{U_i}) = (a^j, \Phi_1(v_i))$ for some $a, b \in \mathbb{Z}_p \setminus \{0\}$; then $i > 1$, say, hence by Lemma 2.1 a factorization $m = uv$ exists such that $u, v$ are $\mathbb{Z}_p$-invariant monomials both containing a variable of weight $a$; we may also suppose that the zero-sum sequence $\Phi(v)$ is irreducible, hence $\deg(v) \leq p$. Then $u \tau(v) \in I_+(R_+) \leq p$ and the monomials in $m - u \tau(v)$ fall under case (i), (ii).

For the graded algebra $R = \mathbb{F}[V]^G$ and a positive integer $k$ the generalized Noether number $\beta_k(R)$ was defined in [3] as the minimal positive integer $d$ such that $R_+$ is generated as a module over $R_k$ by elements of degree at most $d$. Evidently $\beta(R) = \beta_1(R)$. The usefulness of this concept is shown in [3,4].

**Theorem 3.4** Let $W = U_0 \oplus V^{\oplus 2}$ where $V$ is as in Corollary 3.2 and $U_0$ contains only 1-dimensional irreducible $G$-modules. Then $\beta_k(G, W) = kp + 2$. If moreover $\text{char}(\mathbb{F}) = 0$ then $\beta_k(G) = kp + 2$.

**Proof** It suffices to prove that $\beta_k(G, W) \leq kp + 2$ since the reverse inequality follows from a more general statement in [4]. By a straightforward induction on $k$ it is enough to prove that $w \in I_+(R_+) \leq p$ holds for any monomial $w \in I$ with $\deg(w) \geq p + 3$, where $I = \mathbb{F}[W]^A$ and $R = \mathbb{F}[W]^G$. We shall repeatedly use the fact that $I_3 = I_1 R_+ + R_+$ (see [3]). Now, if $\deg_{U_0}(m) \geq 2$ then $m \in I_1 I_{\geq p+1} \subseteq I_+(R_+) \leq p$. If $\deg_{U_0}(m) = 1$ then $m \in I_1 I_2 I_+ + I_+(R_+) \leq p$ by Proposition 3.3 and we are done again. Finally, if $\deg_{U_0}(m) = 0$ then either $m \in I_1 I_2 I_+ + I_+(R_+) \leq p$ by applying Proposition 3.3 twice, in which case we are done, or else $p = 7$ and $m = uv$ where $u \in I_2$ and $\Phi(v) = (a^6, 5a, 3a)$. In this latter case denoting by $s$ the index for which the weight $a$ belongs to $U_3$ we have $\deg_{U_3}(m) = \deg_{U_2}(u) + \deg_{U_1}(v) = 7$, hence $\deg_{V_i}(m) \geq 4$ for some $i \in \{1, 2\}$, and consequently $m \in I_+(R_+) \leq p$ holds by Proposition 3.1.

The second claim follows from the first using a theorem of Weyl (see [27] II. 5 Theorem 2.5A) by extending similar considerations in [23].

**Remark 3.5** Studying the dependence of $\beta_k(G)$ on $k$ lead in [5] to focus on $\sigma(R)$ defined as the minimal positive integer $n$ such that $R$ is finitely generated as a module over its subalgebra $\mathbb{F}[R_{\leq n}]$ generated by the elements of degree at most $n$. Moreover, $\eta(R)$ is the minimal $d$ such that $R_+$ is generated as an $\mathbb{F}[R_{\leq \sigma(R)}]$-module by its elements of degree at most $d$. In [5] it was proved that $\sigma(\mathbb{Z}_p \times \mathbb{Z}_q) = p$ for any odd primes $p, q$ such that $q \mid p - 1$. Therefore the first half of the proof of Theorem 3.4 can be rephrased as stating that $\sigma(\mathbb{Z}_p \times \mathbb{Z}_3) \leq p + 2$.

4 An application for separating invariants

A subset $T \subset \mathbb{F}[V]^G$ is called a separating system if for any $u, v \in V$ belonging to different $G$-orbits there is an element $f \in T$ such that $f(u) \neq f(v)$. A generating system of $\mathbb{F}[V]^G$ is a separating system, but the converse is not true. The study of separating systems was propagated in [6], and is in the focus of several recent papers, see e.g. [7,9,11,17,20]. Following [18] we write $\beta_{se}(\mathbb{F}[V]^G)$ for the minimal $n$ such that there exists a separating system in $\mathbb{F}[V]^G$ consisting of elements of degree at most $n$. Moreover, define $\beta_{se}(G)$ as the maximum of $\beta_{se}(\mathbb{F}[V]^G)$, where $V$ ranges over the isomorphism classes of $G$-modules. Similarly $\sigma(G)$ is defined in [5] as the maximal possible value of $\sigma(\mathbb{F}[V]^G)$. The following
inequalities are well known:

\[ \sigma(G) \leq \beta_{\text{sep}}(G) \leq \beta(G) \quad (4.1) \]

For our group \( G = \mathbb{Z}_p \times \mathbb{Z}_3 \) we have \( \sigma(G) = p \) and \( \beta(G) \geq p + 2 \) by \([4,5]\), and now we shall see that both of the inequalities in \((4.1)\) are strict:

**Theorem 4.1** We have \( \beta_{\text{sep}}(\mathbb{Z}_p \times \mathbb{Z}_3) = p + 1 \).

**Proof** First we will prove the lower bound \( \beta_{\text{sep}}(G) \geq p + 1 \). Recall that \( G = \langle a, b : a^p = b^3 = 1, bab^{-1} = a^r \rangle \), where \( r \) has order 3 modulo \( p \). Let \( U \) and \( V \) be irreducible representations of \( G \) of dimension 1 and 3, respectively. Then \( \mathbb{F}[U \oplus V] = \mathbb{F}[x_1, x_2, x_3] \) where \( y^a = x \) and \( y^b = \omega x \) for a primitive third root of unity \( \omega \), while the \( x_1, x_2, x_3 \) are \( a \)-eigenvectors of eigenvalues \( \epsilon, \epsilon^r, \epsilon^{2r} \) for some primitive \( p \)-th root of unity \( \epsilon \), and \( x_1, x_2, x_3 \) are cyclically permuted by \( b \). Now, the point \((1, 1, 0, 0)\) has trivial stabilizer in \( G \), hence the points \((1, 1, 0, 0)\) and \((\omega, 1, 0, 0)\) do not belong to the same \( G \)-orbit. We claim that they cannot be separated by invariants of degree at most \( p \). Indeed, suppose to the contrary that they can be separated. Then there exists an \( \langle a \rangle \)-invariant monomial \( u \) with \( \deg(u) \leq p \) and \( \tau(u)(1, 1, 0, 0) \neq \tau(u)(\omega, 1, 0, 0) \). If \( u \) involves at least two variables from \( \{x_1, x_2, x_3\} \), then \( \tau(u) \) vanishes on both of \((1, 1, 0, 0)\) and \((\omega, 1, 0, 0)\). If \( u \) involves only \( y \), then \( u = y^k \) for some positive integer \( k \), whence \( \tau(u) \) takes the value 1 both on \((1, 1, 0, 0)\) and \((\omega, 1, 0, 0)\). So \( u \) involves exactly one variable from \( \{x_1, x_2, x_3\} \), forcing that \( u = x_1^p \) and then \( \tau(u) \) agrees on the two given points, a contradiction.

Next we prove the inequality \( \beta_{\text{sep}}(G) \geq p + 1 \). Let \( W \) be the multiplicity free \( G \)-module which contains every irreducible \( G \)-module with multiplicity 1. An arbitrary \( G \)-module is a direct summand in the direct sum \( W^{\oplus n} \) of \( n \) copies of \( W \) for a sufficiently large integer \( n \). According to a theorem of Draisma et al. \([10]\) (see also \([17,19]\)) a separating set of \( \mathbb{F}[W^{\oplus n}]^G \) can be obtained by "cheap" polarization from a separating set of \( \mathbb{F}[W]^G \), which is a degree-preserving procedure, whence \( \beta_{\text{sep}}(\mathbb{F}[W^{\oplus n}]^G) = \beta_{\text{sep}}(\mathbb{F}[W]^G) \) and consequently

\[ \beta_{\text{sep}}(G) = \beta_{\text{sep}}(\mathbb{F}[W]^G) \quad (4.2) \]

Now let \( W = U \oplus V \) where \( U \) is the sum of 1-dimensional irreducibles, and \( V \) is the sum of 3-dimensional irreducibles. Suppose that \((u_1, v_1)\) and \((u_2, v_2)\) belong to different \( G \)-orbits in \( U \oplus V \). We need to show that they can be separated by a polynomial invariant of degree at most \( p + 1 \). If \( u_1 \) and \( u_2 \) belong to different \( G \)-orbits, then they can be separated by a polynomial invariant of degree at most \( 3 = |G/A| \) (recall that \( A \) acts trivially on \( U \)), and we are done. From now on we assume that \( u_1 \) and \( u_2 \) have the same \( G/A = B \)-orbits. If \( v_1 \) and \( v_2 \) belong to different \( G \)-orbits in \( V \), then they can be separated by a \( G \)-invariant on \( V \) of degree at most \( p \) by Corollary 3.2 and we are done. It remains that \( v_1 = gv_2 \) for some \( g \in G \); after replacing \((u_2, v_2)\) by an appropriate element \( v_1 = v_2 = v \) might be assumed, and then \( u_1 \) and \( u_2 \) are not on the same orbit under the stabilizer \( \text{Stab}_G(v) \) of \( v \). Consequently \( \text{Stab}_G(v) \) is contained in \( A \) (for otherwise \( \text{Stab}_G(v) \) is mapped surjectively onto \( G/A \)). Let \( U_0 \) be a 1-dimensional summand in \( U = U_0 \oplus U_1 \) such that \( \pi(u_1, v) \neq \pi(u_2, v) \), where \( \pi : U \oplus V \to U_0 \) is the projection onto \( U_0 \) with kernel \( U_1 \oplus V \). Denote by \( y \) the coordinate function on \( U_0 \), viewed as an element of \( \mathbb{F}[U \oplus V] \) by composing it with \( \pi \). If \( G \) acts trivially on \( U_0 \), then \( y \) is a \( G \)-invariant of degree 1 that separates \((u_1, v)\) and \((u_2, v)\). Otherwise \( y^g = \chi(g)^{-1}y \) for some non-trivial group homomorphism \( \chi : G \to \mathbb{K}^\times \). By Lemma 4.3 below, there is an \( f \in \mathbb{F}[V]^{G \cdot \chi} := \{ h \in \mathbb{F}[V] \mid h^g = \chi(g)h \ \forall g \in G \} \) such that \( f(v) \neq 0 \). Moreover, since a twisted version of the relative transfer map gives an \( R \)-module surjection \( I \to \mathbb{F}[V]^{G \cdot \chi} \) (see in the proof of Lemma 4.3) we infer from Corollary 3.2 that \( \mathbb{F}[V]^{G \cdot \chi} \) is
generated as an $F[V]^G$-module by its elements of degree at most $p$, hence we may assume that $f$ has degree at most $p$. Now $\gamma f$ is a $G$-invariant of degree at most $p + 1$ which separates $(u_1, v)$ and $(u_2, v)$ by construction.

Remark 4.2 Note that by a straightforward extension of the argument in the first part of the above proof we get $\beta_{\text{sep}}(Z_p \times Z_q) \geq p + 1$ for any $q \mid p - 1$.

Lemma 4.3 Given a group homomorphism $\chi : G \to F^\times$ and any point $v \in V$ such that $\text{Stab}_G(v) \leq \ker(\chi)$, a relative invariant $f \in F[V]^{G,\chi}$ exists for which $f(v) \neq 0$.

Proof Let $g_1, \ldots, g_n \in G$ be a system of representatives of the left cosets of the subgroup $\text{Stab}_G(v)$. Then $g_1 v, \ldots, g_n v \in V$ are distinct. Therefore there exists a polynomial $h \in F[V]$ such that $h(g_i v) = \chi(g_i)$ for each $i = 1, \ldots, n$. Now set $f := \tau_\chi(h)$ where $\tau_\chi : F[V] \to F[V]^{G,\chi}$ is the twisted transfer map defined as $\tau_\chi(h) := \sum_{g \in G} \chi(g)^{-1} h^g$. Then $f \in F[V]^{G,\chi}$ by construction. Moreover, since $\text{Stab}_G(v) \leq \ker(\chi)$ we have
\[
f(v) = \sum_{g \in G} \chi(g)^{-1} h(g v) = |\text{Stab}_G(v)| \sum_{i=1}^n \chi(g_i)^{-1} h(g_i v) = |G|
\]
which is indeed a non-zero element in $F$. □
