Formation of Large-Amplitude Low-Frequency Waves in
Capillary Turbulence on Superfluid He-II

The results of experimental and theoretical studies of the parametric decay instability of capillary waves on the surface of superfluid helium He-II are reported. It is demonstrated that in a system of turbulent capillary waves low-frequency waves are generated along with the direct Kolmogorov-Zakharov cascade of capillary turbulence. The effects of low-frequency damping and the discreteness of the wave spectrum are discussed.

I. INTRODUCTION

Highly developed hydrodynamic turbulence has provided a fascinating challenge for engineers, physicists and mathematicians for over two hundred years. Turbulence appears in numerous systems ranging from planetary waves in the earth’s atmosphere to jet streams [1, 2]. Fully developed hydrodynamic turbulence can be formed by interacting vortices [3]. Turbulence may also appear in a system of nonlinearly interacting waves [4, 5], which is referred to as wave turbulence. The concept of wave turbulence originated from Peierls’ work [6] on anharmonic crystals. Wave turbulence is manifested on planetary and interstellar scales, in the earth’s magnetosphere and its coupling with the solar wind [7], in shock propagation in Saturn’s bow [8], and in interstellar plasmas [9]. Fascinating atmospheric phenomena, such as auroras in the high-latitude regions of the earth, are caused by ion wave turbulence in magnetic flux tubes [7]. Wave turbulence also provides deep connections between the classical and quantum worlds; wave turbulence can result in kinetic condensation of classical waves [10], which is similar in many ways to Bose-Einstein condensation in quantum systems such as ultra-cold atoms [11].

Wave turbulence is much easier to understand than hydrodynamic turbulence, because it is appropriate when the building blocks of a system are linear waves that admit analytical descriptions. When the nonlinear interactions between waves may be treated as weak perturbations, the statistics of the system become tractable analytically. This allows one to derive the closed equation for the spectral energy density of the waves, called the kinetic equation. The kinetic equation for interacting waves has a steady-state scale invariant (power-law) solution that describes a constant flux of energy towards smaller scales. Such a power law spectrum can be viewed as the wave analog of the Kolmogorov spectrum of hydrodynamic turbulence [3] and is referred to as the Kolmogorov-Zakharov (KZ) spectrum of wave turbulence [4, 5].

Surface capillary waves are the ripples that are created by a light breeze on the surface of a pond. They are short waves for which surface tension is the primary restoring force. The dispersion relation between the wave frequency $\omega$ and the wave number $k$ for capillary waves is

$$\omega(k) = \sqrt{\frac{\alpha k^3}{\rho}}, \tag{1}$$

where $\alpha$ is the surface tension and $\rho$ is the fluid density. For water, the characteristic wave length of capillary waves is less than $\lambda = 2\pi \sqrt{\alpha/\rho g} \approx 1.7 \text{ cm}$ (where $g$ is the acceleration due to gravity). Capillary waves are a beautiful canonical example of a wave-turbulent system with weak nonlinear wave interactions. The Kolmogorov-Zakharov spectrum of capillary waves corresponds to the direct cascade, or flux of wave energy, from low to high wave frequencies. The existence and features of the KZ spectrum for capillary waves is well established through both experiments and theory [12–17].

We study capillary waves on the surface of superfluid helium. This system provides an ideal testbed for studying nonlinear wave dynamics due to its extremely low viscosity and the possibility of driving the fluid surface directly by an oscillating electric field, virtually excluding the excitation of bulk modes [15]. Previous experiments with waves on quantum fluids (liquid helium and hydrogen) allowed detailed study of the steady-state and decaying direct cascade of capillary turbulence [16–17], modification of the turbulent spectrum by applied low-frequency driving [18], and the turbulent bottleneck phenomena in the high-frequency spectral domain [19].

In this paper, we show that under certain conditions low-frequency waves on the fluid surface with frequencies lower than the driving frequency can be created in addition to the direct Kolmogorov-Zakharov cascade. In what follows we present our findings and discuss the mechanisms responsible for the low-frequency wave generation.
FIG. 1: Long-time evolution of the spectrum of capillary turbulence. The spectra are shown for the moments (a) $t = 1.31$ s, (b) 53.74 s and (c) 163.84 s after the driving force is turned on. Driving is applied at a frequency $\omega_d/2\pi = 199$ Hz, the driving amplitude is $U_d = 97$ V. Formation of low-frequency harmonics with $\omega < \omega_d$ are clearly seen in figures (b) and (c). The squared amplitudes of the harmonics $|P_\omega|^2$ are shown in arbitrary units.

II. EXPERIMENTAL OBSERVATIONS

The experimental arrangements were similar to those in our previous experiments with superfluid helium and liquid hydrogen [16, 17]. In our experiments, helium $^4$He was condensed into a cylindrical cup formed by the bottom capacitor plate and a guard ring and was positioned in a helium cryostat. The cup has inner radius $R = 30$ mm and depth 4 mm. The experiments were conducted at temperature $T = 1.7$ K of the superfluid liquid. The free surface of the liquid was positively charged as the result of $\beta$–particle emission from the radioactive plate located in the bulk liquid. Oscillations of the liquid surface were excited by application of an AC voltage $U(t) = U_d \sin(\omega_d t)$ to the lower capacitor's plate in addition to the constant voltage. Oscillations of the fluid surface elevation $\zeta(r,t)$
were detected through variations of the power $P(t)$ of a laser beam reflected from the surface. (Here, $t$ is time and $r$ is two-dimensional coordinates in the surface plane). The power $P(t)$ was measured with a photodetector and sampled with an analogue-to-digital converter. The capillary wave power spectrum $\zeta_\omega \propto P_\omega$ was calculated via the time Fourier transform of the signal $P(t)$. The measurements of wave damping in the cell showed that the quality factor at low frequencies $\omega < \omega_d$ is $Q \sim 10^3$. The finite size of the cell results in the discrete wave number spectrum. The capillary-to-gravity wave transition on the surface of superfluid helium is at frequency $\sim 30$ Hz. The surface oscillations with frequencies $\sim 30$ Hz are gravity-capillary waves, for which the restoring force is caused by both the capillary force and gravity. However, this frequency decreases at high pulling external electric fields normal to the surface. The finite depth of the waves only influences the wave dispersion $\omega = \omega(k)$ at low frequencies $\omega < 10$ Hz. The capillary wave length for liquid helium is $\lambda = 0.17$ cm at $T = 4.2$ K and increases to 0.3 cm for $T = 1.7$ K.

Figure 1 shows formation of a wave-turbulent spectrum after switching on the driving force at the moment of time $t = 0$. The driving frequency is $\omega_d/2\pi = 199$ Hz. In Fig. 1, waves with the frequency $\omega_d$ and its high-frequency harmonics begin to form on the noisy background. The latter is caused by mechanical vibrations of the installation. In Fig. 1c, the Kolmogorov-Zakharov direct cascade of capillary turbulence is formed at $\omega > \omega_d$. It corresponds to transfer of the wave energy in a cascade-like manner towards higher frequency, in full agreement with our previous observations. At frequencies $\omega/2\pi \sim 20$ kHz, the cascade is cut due to viscous damping in the fluid. The peak at 20.5 kHz is caused by the noise of the He-Ne laser output power.

It is seen in Fig. 1c that low-frequency waves with $\omega < \omega_d$ are formed at large time $t \geq 50$ s after the drive is turned on. Specifically, the squared amplitude of the harmonics at $\omega_d/2\pi = 99$ Hz is $|P_\omega|^2 \approx 8.3\times10^9$ a.u. at $t = 53.74$ s (Fig. 1a), and it reaches $|P_\omega|^2 \approx 2.2\times10^{11}$ a.u. at $t = 163.84$ s (Fig. 1b). It is remarkable that in Fig. 1b, the amplitude of the subharmonics is larger than that for the wave at the drive frequency, which is $|P_\omega|^2 \approx 1.5\times10^{11}$ a.u. The amplitudes of the low-frequency harmonics at $\omega/2\pi \approx 10$ Hz shown in Fig. 1d are larger than the amplitudes of the high-frequency waves in the direct cascade with $\omega/2\pi \geq 500$ Hz. It is worth noting that formation of the low-frequency harmonics on a turbulent capillary-wave background has not yet been reported in the literature.

Generation of low-frequency waves shown in Fig. 1d can be attributed to the development of the decay instability of capillary waves at enough large wave amplitudes. The origin of this instability is in the modulation of a nearly periodic wave due to nonlinearity. This specific mechanism was earlier proposed to account for the formation of giant low-frequency waves on the water surface. It was also demonstrated that for waves on an ideal fluid with no damping, development of the decay instability should result in formation of a thermodynamic-equilibrium wave distribution $|P_\omega|^2 \propto \Theta/\omega(k)$ where $\Theta$ is the effective temperature. However, it is seen in Fig. 1d that the observed spectrum at $\omega < \omega_d$ significantly differs from the proposed theoretical equilibrium spectrum.

### III. NUMERICAL SIMULATIONS

To understand the formation of large-amplitude low-frequency waves, we performed numerical modeling of the wave dynamics in the cylindrical cell with external driving and viscous damping. In the simulations, the deviation of the surface from the equilibrium flat state is expressed by time-dependent amplitudes $a_k(t)$ of the normal modes. We assume angular symmetry of the surface, so its deviation for capillary waves is $\zeta(r, t) = \sum_k \sqrt{\frac{\kappa}{2w_k}} \beta_k \cos(kr)$, where $r$ is the distance from the center of the cell, $J_0(x)$ is the Bessel function of the zero order, $\kappa$ is the free-surface area, $\omega(k)$ is the linear dispersion relation, $k = k_n = \beta_n/R$ is the radial wave number, $n > 0$ is an integer index labelling the resonant radial modes, and $a_k(t)$ is the $n$th zero of the first order Bessel function $J_1(\beta_n) = 0$. In the simulations $r$ is measured in the capillary length scale $\lambda_c = (\alpha/\rho g)^{1/2}$, and time $t$ is measured in the units of $t_c = \omega_c^{-1}$, where $\omega_c = (\rho g^3/\alpha)^{1/4}$. The driving force is applied at a given radial mode $k_d$. Due to angular isotropy, we utilize the angle-averaged dynamical equation for $a_k(t)$:

$$\frac{da_k(t)}{dt} = -\frac{1}{\sum_{k_1, k_2} V_{k, k_1, k_2} D_{k, k_1, k_2} a_{k_1}(t) a_{k_2}(t) e^{i(\omega(k) - \omega(k_1) - \omega(k_2))t}} - 2\frac{1}{\sum_{k_1, k_2} V_{k, k_1, k_2} D_{k, k_1, k_2} a_{k_1}(t) a_{k_2}(t) e^{i(\omega(k) + \omega(k_2) - \omega(k_1))t}} - \gamma(\omega(k)) a_k(t).$$

The coupling coefficient $V_{k, k_1, k_2}$ characterizes the interaction strength between waves with wave numbers $k$, $k_1$ and $k_2$. Instead of taking the exact value for capillary waves, we model it by $V_{k, k_1, k_2} = \epsilon \sqrt{\omega(k)\omega(k_1)\omega(k_2)}$. Star denotes complex conjugate, $i$ stands for the imaginary unit, and $D_{k_1, k_1, k_2} = 1/2\pi \Delta(k, k_1, k_2)$, where $\Delta(k, k_1, k_2)$ is the area of the triangle with sides $k$, $k_1$, and $k_2$. We consider $n_{max} = 100$ radial modes. The dimensionless factor $\epsilon \ll 1$ characterizes nonlinearity of the system and is of the order of the maximum surface slope with respect to the horizontal. We set $\epsilon = 10^{-2}$ as a representative value. Due to the small nonlinearity, we only retain three-
I. INTRODUCTION

Wave interactions in Eq. (2); the inclusion of four-wave scattering requires special consideration [23] and is deferred to future studies.

We chose numerical parameters that are representative of our experimental setup and determined the steady-state wave spectrum from our model. Specifically, we drive the system in the middle of our numerical spectral range, at the 50th resonant frequency of the cell. We also add wave damping at both high and low frequencies, to mimic the physical effects that remove energy from the system. Specifically, we model the wave damping coefficient as

\[ \gamma(\omega) = \gamma_{<}(\omega) + \gamma_{>}(\omega), \]

which is the sum of damping at low frequencies below the 10th resonance in the cell, with \( \gamma_{<}(\omega) = \gamma_{1} g_{<}(\omega) \), as well as damping at high frequencies above the 80th resonance with \( \gamma_{>}(\omega) = \gamma_{0} g_{>}(\omega) \). Low-frequency damping is the result of viscous drag at the cell’s bottom [24], and high-frequency damping models the energy loss due to bulk viscosity in the fluid [3]. The range of wave frequencies between the 10th and 80th resonant frequencies can be considered as a “numerical inertial interval”, in which damping is absent.

Driving was at the 50th mode by fixing the wave amplitude \( a_{d} \equiv |a_{k_{d}}(t)| \) at a given value set; in the present simulations as \( (\lambda\omega/\omega_{d})^{-1/2}a_{d} = 0.1 \). The dimensionless damping factor at high frequencies was set \( \gamma_{0} = 5 \times 10^{-2} \omega_{c} \). We apply damping at high resonant numbers \( n > n_{>} = 80 \) for which we set \( g_{>}(n) = (n - n_{>})^{2}/(n_{\text{max}} - n_{>})^{2} \), and \( g_{>}(n) = 0 \) for \( n \leq n_{>}. \) To model waves on a fluid layer of finite depth, we also apply damping at low resonant numbers \( n < n_{<} = 10 \) as follows \( g_{<}(n) = (n_{<} - n)/n_{<} \), and \( g_{<}(n) = 0 \) for \( n \geq n_{<}. \) To calculate the dependence of \( a_{k}(t) \) on time \( t \), we integrated Eq. (2) until the system reached the steady state. We found numerical convergence and energy conservation with \( 10^{-7} \) numerical accuracy. The normalized wave spectrum is calculated as the time-averaged \( N(k) = \langle |a_{k}(t)|^{2} \rangle. \) To facilitate the comparison of the simulation results with the experimental data, the spectrum \( I_{\omega} \equiv N(k) \) is expressed as a function of the wave frequency \( \omega \) via the relation \( k = k(\omega) \) from the inverse of the dispersion relation Eq. (1).

The results of the simulations for \( \gamma_{1} = 0.5 \gamma_{0} \) are shown in Fig. 2. It is evident that the harmonics with a frequency \( \omega < \omega_{d} \) are formed. The amplitudes of the low-frequency harmonics in the spectral range \( 0.2 \omega_{d} < \omega < \omega_{d} \) are of the order of or larger than the amplitude at the driving frequency. This result is in qualitative agreement with the result of the observation shown in Fig. 1b,c. In particular, it is seen in Fig. 2 that the numerical spectrum \( I_{\omega} \) differs from a power-like equilibrium spectrum predicted for waves on an ideal fluid. The reason of this discrepancy can lie in finite damping at low frequencies in our observations and in the numerical model. The deviation of the low-frequency spectrum can also be caused by the discreteness of the spectrum of resonant waves at low frequencies in a cell of finite size, in agreement with results of Refs. [25–27].

IV. CONCLUSIONS

We demonstrated that if the capillary waves on a superfluid helium surface are driven at high enough frequency, large-amplitude low-frequency waves are created in addition to Kolmogorov-Zakharov cascade of capillary turbulence.
We infer that the reason for the low-frequency wave generation is the decay instability of capillary waves. This mechanism is previously known to be responsible for the inverse cascade of gravity waves on the ocean surface. The observed spectrum of low-frequency waves differs from a pure thermal-equilibrium distribution predicted for waves on an ideal fluid. This discrepancy can be caused by the effects of viscous damping and by a restricted geometry of the cell. Our experimental findings are in agreement with the results of the numerical simulations based on the wave dynamic equations.
