2-Phenyl-N,N’-bis(pyridin-4-ylcarbonyl)butanediamide ligand with a series of transition metal complexes has been synthesized via two routes: microwave irradiation and conventional heating method. Microwave irradiation method happened to be the efficient and versatile route for the synthesis of these metal complexes. These complexes were found to have the general composition $\text{M(L)Cl}_2/\text{M(L)(CH}_3\text{COO)}_2$ (where $\text{M} = \text{Cu(II), Co(II), Ni(II), and L} = \text{ligand}$). Different physical and spectroscopic techniques were used to investigate the structural features of the synthesized compounds, which supported an octahedral geometry for these complexes. In vitro antifungal activity of the ligand and its metal complexes revealed that the metal complexes are highly active compared to the standard drug. Metal complexes showed enhanced activity compared to the ligand, which is an important step towards the designing of antifungal drug candidates.

1. Introduction

Nicotinamide is known as a component of the vitamin B complex as well as a component of the coenzyme, nicotinamide adenine dinucleotide (NAD). It is documented that heterocyclic compounds play a significant role in many biological systems, especially N-donor ligand systems being a component of several vitamins and drugs such as nicotinamide [1–3]. The presence of pyridine ring in numerous naturally abundant compounds is also of scientific interest. Nicotinamide itself plays an important role in the metabolism of living cells and some of its metal complexes are biochemically active as antibacterial or insulin-mimetic agents [4]. Therefore, the structure of nicotinamide has been the subject of many studies [5–8]. Uses of metal ions in therapeutic agents are known to accelerate drug action and their efficacy enhances upon coordination with a metal ion [9, 10]. The classical coordination complex, cis-DDP or cisplatin (cisdiammine dichloroplatinum), has been the subject of much recent attention towards the metal-based chemotherapy, because of its beneficial effects in the treatment of cancer. These compounds present a great variety of biological activities, namely antitumour [II], antimicrobial [12, 13], anti-inflammatory, and antiviral activities. The inherent biological potential of sulphur/nitrogen donor ligands prompted us to undertake systematic studies with transition metals. In case of N and C based functionalized macrocyclic ligands, the mode of metal incorporation is very much similar to that of metalloproteins in which the requisite metal is bound in a macrocyclic cavity or cleft produced by the conformational arrangement of the protein [14]. The attachment of metal ions to proteins such as monoclonal antibodies can create new tools for use in biology and medicine [15]. These types of ligands have theoretical importance also because they
are capable of furnishing an environment with controlled geometry and ligand field strength [16, 17]. The reagents used for such attachments are called bifunctional chelating agents [18]. The precise molecular recognition between macrocyclic ligands and their guest provides a good opportunity for studying key aspects of supramolecular chemistry, which are also significant in a variety of disciplines including chemistry, biology, physics, medicine and related science, and technology [19].

*Candida albicans* is an opportunistic and often deadly pathogen that attacks host tissues, undergoes a dimorphic shift, and then grows as a fungal mass in the kidney, heart, or brain. It is the fourth leading cause of hospital-acquired infection in the United States and over 95% of AIDS patients suffer from infections by *C. albicans* [20, 21]. *Candida albicans* is the predominant organism associated with candidiasis; but other *Candida* species, including *C. glabrata*, *C. tropicalis*, and *C. krusei*, are now emerging as serious nosocomial threats to patient populations [22]. The current antifungal therapy suffers from drug related toxicity, severe drug resistance, nonoptimal pharmacokinetics, and serious drug–drug interactions. The common antifungal drugs currently used in clinics belong to polyenes and azoles. Polyenes (amphotericin B and nystatin) cause serious host toxicity [23], whereas azoles are fungistatic and their prolonged use contributes to the development of drug resistance in *C. albicans* and other species [24]. Because of all these striking problems, there is an immediate need to develop novel antifungal drugs with higher efficiency, broader spectrum, improved pharmacodynamic profiles, and lower toxicity. In view of the importance of transition metal complexes in chemotherapy and as part of our continuing interest in metal complexes, we report herein the synthesis, characterization, and *in vitro* antifungal study of 2-phenyl-N,N′-bis(pyridin-4-ylcarbonyl)butanediamide and its metal complexes.

2. Experimental

All the chemicals used were of analytical grade and were procured from Aldrich. Metal salts were purchased from E. Merck and used as received. All solvents used were of standard/spectroscopic grade. All synthesis and handling were carried out under an atmosphere of dry and oxygen-free nitrogen using standard Schlenk techniques and samples for microanalysis were dried in vacuum to constant weight.

2.1. Physical Measurements. Elemental analyses were performed by a Perkin Elmer 2400 CHNSO Elemental Analyser. FT-IR spectra of solid samples were recorded on a Perkin Elmer Spectrum 100 FT-IR spectrometer (Universal/ATR Sampling Accessory). Bruker DPX-300 MHz spectrophotometer was used to record $^1$H NMR spectra at room temperature with DMSO $d_6$ as solvent. The chemical shift ($\delta$) is reported in parts per million (ppm) using tetramethylsilane as internal standard. Positive and negative ESI mass spectra were measured by Bruker (esquire 3000-00037) instrument. Magnetic susceptibility measurements were approved from a microanalysis laboratory by the Gouy method at room temperature. Electronic spectra were recorded on a spectro-UV-Vis Dual Beam 8 auto cell UVS-2700 LABOMED, Inc. US spectrophotometer using DMSO as solvent. Melting points (mp) were recorded on a Metrex melting point apparatus and the results are uncorrected.

2.2. Synthesis of Ligand (L)

2-Phenyl-N,N′-bis(pyridin-4-ylcarbonyl)butanediamide. Two different routes were employed for the synthesis of the ligand.

2.2.1. Microwave Assisted Synthesis. The ligand (L) was prepared by the condensation of phenylsucinic acid (0.97 g, 5 mmol) with nicotinamide (1.22 g, 10 mmol). The reaction mixture was irradiated by the conventional microwave oven by taking 2-3 mL solvent. The reaction was completed in a short period (3-4 min). The resulting precipitate was then recrystallized from alcohol and dried under vacuum. These were characterized and analysed before use. Elemental analyses were conducted using the methods mentioned above and their results were found to be in good agreement with the calculated values. The structure of the ligand has been shown in Scheme 1.

Yield 95%, mp. 180°C, IR (KBr, cm$^{-1}$): 3483 (N–H), 2985 (C–H), 1645 (C=O), 1580 (C–N), 1012, 863, 741; $^1$H NMR (300 MHz, $\delta$ ppm from TMS in DMSO–$d_6$, 300 k): $\delta$ 8.01–7.17 (13H, Ar–C–H), $\delta$ 11.70–11.62 (2H, OC–NH), $\delta$ 2.88–2.63 (1H, OC–CH$_2$). ESI MS (m/z) 402 [M]$^+$, 403 [M+1]$^+$. Elem anal calc. C 65.66, H 4.51, N 13.92%; found C 66.22, H 4.75, N 14.01.

2.2.2. Conventional Thermal Method. For comparison purposes, the above ligand was also synthesized by the thermal method. In this method, 100 mL of ethanol was used to dissolve the starting materials of the ligand and the contents were refluxed for nearly 6-7 h. The residue formed was separated out, filtered off, washed with water, recrystallized from ethanol, and finally dried in vacuum over fused calcium chloride (yield 82%), mp. 180°C. A comparison between thermal method and microwave method is given in Table I.

2.3. Synthesis of Metal Complexes

2.3.1. Microwave Assisted Synthesis. The ligand and metal salts were mixed in 1:2 (metal:ligand) ratio in a grinder. The reaction mixture was then irradiated by the microwave oven by taking 3–5 mL solvent. The reaction was completed in a short time (5–7 min) with higher yields. The resulting product was then recrystallized from ethanol and ether and finally dried under reduced pressure over anhydrous CaCl$_2$ in a desiccator. The progress of the reaction and purity of product was monitored by TLC using silica gel G.

2.3.2. Conventional Thermal Method. These complexes were also synthesized by the thermal method where instead of 5–7 min, reactions were completed in 4-5 h and the yield of the products was also less than that obtained by the microwave assisted synthesis.
Scheme 1: Synthesis of ligand and its metal complexes.

Table 1: Comparison between microwave and thermal method.

| Compound          | Yield (%) | Solvent (mL) | Time |
|-------------------|-----------|--------------|------|
|                   | Thermal   | Microwave    | Thermal | Microwave | Thermal (h) | Microwave (min) |
| [C\textsubscript{22}H\textsubscript{18}N\textsubscript{4}O\textsubscript{4}] | 82        | 95           | 100    | 2         | 7           | 3               |
| [CoLCl\textsubscript{2}] | 75        | 87           | 40     | 4         | 5           | 5               |
| [CoL(CH\textsubscript{3}COO)\textsubscript{2}] | 76        | 86           | 40     | 3         | 5           | 6               |
| [NiLCl\textsubscript{2}] | 78        | 85           | 40     | 5         | 5           | 5               |
| [NiL(CH\textsubscript{3}COO)\textsubscript{2}] | 72        | 82           | 40     | 4         | 4           | 6               |
| [CuLCl\textsubscript{2}] | 69        | 79           | 40     | 4         | 5           | 7               |
| [CuL(CH\textsubscript{3}COO)\textsubscript{2}] | 73        | 83           | 40     | 3         | 4           | 6               |

L = [(C\textsubscript{22}H\textsubscript{18}N\textsubscript{4}O\textsubscript{4})].
2.3.3. [M(L)Cl₂/M(L)(CH₃COO)]₂ Type of Complexes. M(L)Cl₂/M(L)(CH₃COO)₂ (where M = Cu(II), Co(II), Ni(II), and L = ligand).

A hot ethanolic (20 mL) solution of the corresponding metal salts (0.05 mmol) was added to a hot ethanolic (20 mL) suspension of the macrocyclic ligand (0.10 mmol). The mixture was stirred for 4-5 hours at 30°C and the solution was reduced to half of its volume. It was then allowed to stand overnight in a refrigerator. A coloured complex precipitated out, which was isolated by filtration under vacuum. It was washed systematically with cold ethanol and dried in vacuum over P₂O₅.

2.4. Antimicrobial Activity

2.4.1. Yeast Strains, Media, and Growth Conditions. The Candida strains were cultured in yeast extract, peptone, and dextrose (YEPD) broth and maintained on YEPD agar plates at 4°C. The strains were cultured in yeast extract, peptone, and dextrose (YEPD) broth and maintained on YEPD agar plates. The culture medium background was subtracted from assay results and percentage cytotoxicity was calculated with the following equation, using average absorbances for controls and experimental results as shown earlier [27].

\[
\text{Cytotoxicity} = \frac{100 \times (\text{Cell Control} - \text{Experimental})}{(\text{Cell Control})}
\]

3. Results and Discussion

On the basis of elemental analyses, the complexes were assigned the composition shown in Table 2. The analytical data of the complexes correspond well with the general formula [M(L)Cl₂/M(L)(CH₃COO)₂], where L = ligand and M = Co(II), Ni(II), Cu(II). The molar conductance indicates that all the complexes are 1:2 electrolytes in nature.

3.1. Infrared Spectra. Assignments of selected characteristic IR band positions provide significant indication for the formation of ligand (L) and its complexes. The appearance of new bands in the IR spectra at 1645 \( \nu(C=O) \) amide I, 1580 \( \nu(C-N) + \delta(N-H) \) amide II, and 1255 \( \delta(N-H) \) amide III are characteristic for amide groups (Table 3). A sharp band observed in the region of 3483 cm⁻¹ may be assigned to \( \nu(N=H) \) of the amide group [28].

On complexation, the position of \( \nu(N-H) \) and \( \nu(C-N) \) bands shifting to a lower frequency compared to macrocyclic ligand indicates that the coordination takes place through the nitrogen \( [N_{4}] \) core and a new medium intensity band appearing at 420-465 cm⁻¹ attributed to \( \nu(M-N) \) also designates that the flow of electron density towards the metal atom is through the nitrogen group [29]. Another medium intensity band in the region of 340-360 cm⁻¹ has been assigned to \( \nu(M-Cl) \). The presence of bands in the regions of 1595–1560 cm⁻¹ and 1330–1315 cm⁻¹ are characteristic of...
ligand because of the paramagnetic effect of metal (II) ions respectively, with 

\[ L_\text{= [C}_{22}\text{H}_{18}\text{N}_{4}\text{O}_{4}] \].

Table 3: Relevant IR spectral peaks (cm\(^{-1}\)) and their assignments.

| Complexes | \( \gamma \text{ N–H} \) | Amide-I \( \gamma \text{ C=O} \) | Amide-II \( \gamma \text{ C–N, } \delta \text{ N–H} \) | Amide-III \( \delta \text{ N–H} \) | \( \gamma \text{ M–N} \) | \( \gamma \text{ M–Cl} \) (asym) | \( \gamma \text{ M–(CH}_3\text{COO)} \) (sym) |
|------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|
| [C\(_{22}\)H\(_{18}\)N\(_{4}\)O\(_{4}\)] | 3483 | 1645 | 1580 | 1255 | | | |
| [CoL]Cl\(_2\) | 3250 | 1632 | 1565 | 1232 | 445 | 340 | |
| [CoL(CH\(_3\)COO)\(_2\)] | 3165 | 1640 | 1552 | 1225 | 456 | — | 1564 1325 |
| [NiL]Cl\(_2\) | 3153 | 1638 | 1558 | 1242 | 459 | 354 | — |
| [NiL(CH\(_3\)COO)\(_2\)] | 3147 | 1625 | 1569 | 1220 | 454 | — | 1595 1315 |
| [CuL]Cl\(_2\) | 3150 | 1630 | 1570 | 1238 | 425 | 350 | — |
| [CuL(CH\(_3\)COO)\(_2\)] | 3145 | 1628 | 1563 | 1222 | 432 | — | 1560 1330 |

\[ L_\text{= [C}_{22}\text{H}_{18}\text{N}_{4}\text{O}_{4}] \].

asymmetric and symmetric COO\(^-\) stretching vibrations, respectively, with \( \Delta \nu = \approx 250 \text{ cm}^-1 [30] \).

3.2. \(^1\)H NMR Spectra. \(^1\)H NMR spectral data of the ligand in DMSO \( d_6 \) shows the signals corresponding to the proposed structure, as it does not show any signal corresponding to the primary amine group and alcoholic proton. The ligand shows a multiplet in the region of 8.01–7.17 ppm Ar–CH (13H), due to the presence of aromatic ring protons. There is a sharp signal in the range of 11.70–11.62 ppm which is attributed to amide CO–NH, (2H) [31–33]. Another signal appearing in the range of 2.88–2.63 ppm has been ascribed to methylene protons OC–CH\(_2\), (1H). These proton signals undergo down field shifting in all the metal complexes of the ligand because of the paramagnetic effect of metal (II) ions and hence support the coordination of the ligand towards the metal ions [34, 35].

3.3. Electrospray Ionization Mass Spectra (ESI MS). The mass spectra of ligand (L) confirm the proposed formula by showing a peak at \( m/z \) 403 corresponding to the moiety \([C\(_{22}\)H\(_{18}\)N\(_{4}\)O\(_{4}\)]^+\) atomic mass \( m/z \) 402. The series of peaks in the range \( m/z \) 76, 120.7, 164.6, 230, 349, and so forth may be assigned to various fragments. Their intensity gives an idea of the stability of fragments. [M+2]^+ peaks were observed in [CoL]Cl\(_2\), [NiL]Cl\(_2\), and [CuL]Cl\(_2\) metal complexes, possibly due to the presence of isotopic chlorine in low quantities [35]. In some cases, the molecular ion peak was also associated with the solvent, water molecules, and some adducts from the mobile phase solution [36, 37] (Table 2).

3.4. Bands due to Anions

3.4.1. Cobalt(II) Complex. At room temperature the magnetic moment of cobalt(II) complexes lie in the range of 4.82–4.98 B.M. corresponding to three unpaired electrons [38]. The electronic spectra of cobalt(II) complexes exhibit absorption in the region 11,180–11,450 cm\(^{-1}\), 14,710–16,680 cm\(^{-1}\), 18,550–18,959 cm\(^{-1}\), and 25,130–29,750 cm\(^{-1}\). These bands may be assigned to \( ^4T\text{f}_g (F) \rightarrow ^4T\text{f}_g (F) \) \( (\gamma_1) \), \( ^4T\text{f}_g \rightarrow ^4A\text{g} (\gamma_2) \), and \( ^4T\text{f}_g (F) \rightarrow ^4T\text{f}_g (P) \) \( (\gamma_3) \) transitions, respectively, and the fourth band may be due to charge transfer, suggesting an octahedral geometry around cobalt(II) ion [39].

3.4.2. Copper(II) Complex. The magnetic moment of all the Cu(II) complexes recorded at room temperature lie in the
range 1.90–1.99 B.M. corresponding to one unpaired electron. The electronic spectra of the copper(II) complexes display bands in the range 10,263–11,486 cm\(^{-1}\), 18,435–18,650 cm\(^{-1}\), and 29,433–29,850 cm\(^{-1}\). The first two bands may be assigned to the transitions: \(^2\)B\(_{1g} \rightarrow ^2\)A\(_{1g} (d_{x^2-y^2} \rightarrow d_{z^2}) (\nu_1)\) and \(^2\)B\(_{1g} \rightarrow ^2\)B\(_{2g} (d_{x^2-y^2} \rightarrow d_{xy}) (\nu_2)\), respectively, and third band is due to charge transfer spectra [40].

### 3.4.3. Nickel(II) Complex

The magnetic moment of the Ni(II) complex at room temperature lie in the range of 2.75–2.90 B.M. corresponding to two unpaired electrons. The electronic spectra of Ni(II) complexes display three absorption bands in the region of 10,190–10,210 cm\(^{-1}\), 18,738–18,757 cm\(^{-1}\), and 20,410–21,550 cm\(^{-1}\). These bands may be assigned to \(3\)A\(_{2g}(F) \rightarrow ^3\)T\(_{2g}(F)(\nu_1)\), \(3\)A\(_{2g}(F) \rightarrow ^3\)T\(_{1g}(F)(\nu_2)\), and \(3\)A\(_{2g}(F) \rightarrow ^3\)T\(_{1g}(P)(\nu_3)\), respectively [41], showing six coordinated distorted octahedral geometries as shown in Scheme 1.

### 3.5. Antimicrobial Screening

#### 3.5.1. Assessment of Minimum Inhibitory Concentration (MIC\(_{90}\))

Figure 1 summarizes the \textit{in vitro} susceptibilities of 3 fluconazole-sensitive \textit{Candida} strains against ligand and its metal complexes. The data is reported as MIC which is defined as the lowest concentration required inhibiting 90\% growth in comparison to control (absence of any test compound) for each isolate. The synthesized compounds were found to be active against all the tested \textit{Candida} isolates. The MIC\(_{90}\) of ligand \([\text{C}_{22}\text{H}_{18}\text{N}_{4}\text{O}_{4}]\) against the sensitive isolates of different \textit{Candida} isolates ranged 1300–1500 \(\mu g/mL\), \([\text{CoL}]\text{Cl}_2\) ranged 900–1000 \(\mu g/mL\), \([\text{CoL(CH}_3\text{COO}_2])\) ranged 1000–1100 \(\mu g/mL\), \([\text{NiL}]\text{Cl}_2\) ranged 500–700 \(\mu g/mL\), \([\text{NiL(CH}_3\text{COO}_2])\text{Cl}_2\) ranged 700–900 \(\mu g/mL\), \([\text{CuL}]\text{Cl}_2\) ranged 800–900 \(\mu g/mL\), and that of \([\text{CuL(CH}_3\text{COO}_2])\) ranged 600–800 \(\mu g/mL\), respectively.

#### 3.5.2. Growth Curve Studies

In the case of growth curve studies, the effect of increasing concentrations of the ligand and its complexes on the growth pattern of different fungal species has been studied. Control cells showed a normal pattern of growth with a lag phase of 4 h and an active exponential phase of 8–10 h before attaining stationary phase. An increase in the concentration of test compounds leads to a significant decrease in growth. NiCl\(_2\) complex when treated against \textit{Candida albicans} at a concentration of 40 \(\mu g/mL\) the growth pattern does not change, the lag phase is extended by 4 h, and the stationary phase does not reach the same level of cell growth as in the case of control, and at 60 \(\mu g/mL\) the lag phase is further extended by 2 h. At a concentration of 80 \(\mu g/mL\) (MIC\(_{90}\) level), there is a total inhibition of growth showing a flat line (Figure 2). Fluconazole 20 \(\mu g/mL\) showed the lag phase further extended by 6 h with respect to control. A significant and pronounced effect is observed for all the synthesized complexes. Ni(II), Cu(II), and Co(II) complexes, in a concentration dependent manner, suppressed growth and delayed exponential phases. At MIC\(_{90}\) values complete inhibition of growth was observed.

#### 3.5.3. WST-1 Cytotoxicity Assay

The assay principle is based upon the reduction of the tetrazolium salt (WST-1) to formazan by cellular dehydrogenases that can be assessed visually and quantified spectrophotometrically. The generation of yellow coloured formazan is measured at 450 nm and is directly correlated to cell number. Table 4 gives % cytotoxicity of \textit{C. albicans} STD 31, \textit{Candida glabrata} STD 96, and \textit{Candida kruesi} STD 116 at MIC concentrations of test compounds. All the test compounds show cytotoxicity for all the three fluconazole-susceptible \textit{Candida} isolates used in this study. It was found that MIC\(_{90}\) values of the test compounds showed pronounced cytotoxic effects. The average % cytotoxicity at MIC values of \([\text{CoL}]\text{Cl}_2\), \([\text{CoL(CH}_3\text{COO}_2])\), \([\text{NiL}]\text{Cl}_2\), \([\text{NiL(CH}_3\text{COO}_2])\text{Cl}_2\), \([\text{CuL}]\text{Cl}_2\), and \([\text{CuL(CH}_3\text{COO}_2])\) were 44\%, 35\%, 86\%, 69\%, 59\%, and 76\% against the three types of species. Respective figures at the MIC values of ligand \([\text{C}_{22}\text{H}_{18}\text{N}_{4}\text{O}_4]\) were 20\% only. \([\text{NiL}]\text{Cl}_2\) at its MIC concentrations was found to be the most cytotoxic of all the compounds tested. An increase in cytotoxicity was observed with increase in concentration of the test compounds.

### 4. Conclusion

The synthesis and characterization of 2-phenyl-N,N’-bis(pyridin-4-ylcarbonyl)butanediameide ligand and its
Table 4: % Cytotoxicity by MIC of ligand and its different complexes against three fluconazole-sensitive Candida isolates.

| Complexes (μg/mL)          | Control | Candida albicans STD 31 | Candida glabrata STD 96 | Candida kruesi STD 116 |

L = [C22H18N4O4].

Corresponding Cu(II), Co(II), and Ni(II) complexes have been carried out. The IR, 1H-NMR, and 13C-NMR data were successfully used to elucidate the formation of the 2-phenyl-N,N'-bis(pyridin-4-ylcarbonyl)butanediamide ligand. On the basis of spectral studies an octahedral geometry for metal complexes has been assigned. All the fluconazole-susceptible Candida isolates investigated were found to be sensitive to the test compounds. The use of total mean MICs obtained gave a good indication of the overall antimicrobial effectiveness of each test compound. This may indicate that the yeast physiology may not be better equipped to counteract the antifungal properties of these compounds. The higher activity of [NiL]Cl2 as compared to free ligand [C22H18N4O4] may be attributed to the increased lipophilicity that causes its efficient permeation through the lipid bilayers of the microbial cell membranes and a consequent cell death [42]. Cytotoxicity results obtained suggest that there is a drastic alteration in redox activity of cells and at higher values of metal chelates a maximum decrease in reduction of tetrazolium salt is seen. By combining the results of MIC studies and tetrazolium assays it can be concluded that metal chelates at their MIC90 values show maximum effect either on growth or on metabolic activities of oxidases inside the cell. At higher concentrations, these metal chelates affected redox activity translates decreased growth which eventually leads to maximum growth inhibition at MIC90 values.

Conflict of Interests

The authors declare that there is no conflict of interests regarding the publication of this paper.

Acknowledgments

This Project was funded by the Saudi Basic Industries Corporation (SABIC) and the Deanship of Scientific Research (DSR), King Abdulaziz University, Jeddah, under Grant no. MS/14/393/1433. The authors, therefore, acknowledge with thanks SABIC and DSR technical and financial support.
