Data obtained by genotyping single nucleotide polymorphisms (SNPs) related to high-density lipoprotein cholesterol (HDL-C) levels were utilized in Genetic Risk Score [unweighted (GRS) and weighted (wGRS)] computation on Hungarian general and Roma populations. The selection process of the SNPs as well as the results obtained are published in our research article (Piko et al., 2017) [1]. Linkage analyses were performed by study groups. Study populations were stratified by quintiles of weighted Genetic Risk Score. Multivariate linear regression analyses were performed using Genetic Risk Scores and HDL-C levels as dependent variables; and ethnicity, sex and age as independent variables. The study subjects were categorized into quintiles according their wGRS values. Associations of Genetic Risk Scores with plasma HDL-C levels (as a continuous variable) were observed in both populations. Finally, the two populations were merged and analyzed together by multivariate logistic regression where reduced...
plasma HDL-C level was the dependent variable; while ethnicity, age and sex were the independent ones.

Value of the data

- Several studies describe the health status of the Roma, which constitutes the largest ethnic minority in Europe however studies focusing on their genetic predisposition to common chronic diseases are scarce.
- Genetic background of atherosclerosis among Roma as well as the general Hungarian population can be studied separately or in international cohort.
- Genetic risk score assessment can be further utilized to compare susceptibility to reduced HDL-C level among different population groups.

1. Data

Distribution of SNPs related to HDL-C level were analysed in the Hungarian Roma and general populations and weighted Genetic Risk Scores were defined and used to categorize the population into quintiles.

2. Experimental design, materials and methods

2.1. Subjects

Study involved subjects of samples investigated during recent cross sectional surveys [2,3]. The Roma sample is representative to the Roma population living settlements in North-East Hungary in terms of age and sex and includes 646 individuals (Roma). The “General” sample consisting of 1542
individuals representative for the Hungarian general population in terms of geographic, age and sex distributions.

2.2. DNA extraction

DNA was isolated using a MagNA Pure LC system (Roche Diagnostics, Basel, Switzerland) with a MagNA Pure LC DNA Isolation Kit–Large Volume according to the manufacturer’s instructions. Extracted DNA was eluted in 200 $\mu$l MagNA Pure LC DNA Isolation Kit–Large Volume elution buffer.

2.3. SNP selection

A systematic literature review on the PubMed, HuGE Navigator and Ensembl databases was conducted to identify SNPs most strongly associated with HDL-C metabolism (Table 1 and Fig. 1). The selection process of the SNPs is demonstrated in detail in our research article [1].

2.4. Genotyping

Genotyping was performed on a MassARRAY platform (Sequenom Inc., San Diego, CA, USA) with iPLEX Gold chemistry. Validation, concordance analysis and quality control were conducted by the facility according to their protocols.

2.5. Statistical analyses

Two-sided t tests were used to compare the distribution of genetic risk scores in populations. To reveal the association between genetic risk, serum HDL-C level and ethnicity several statistical models were used (Tables 2–6).

Table 1
List of the SNPs which were involved in the research.

| Nearest Gene | Gene (short) | SNP (rs number) | Chromosome |
|--------------|--------------|-----------------|------------|
| Apolipoprotein B | APOB | rs693 | 2 |
| ATP-binding cassette transporter ABCA1 | ABCA1 | rs4149268 | 9 |
| Cholesteryl ester transfer protein | CETP | rs1532624 | 16 |
| Cholesteryl ester transfer protein | CETP | rs5882 | 16 |
| Cholesteryl ester transfer protein | CETP | rs708272 | 16 |
| Cholesteryl ester transfer protein | CETP | rs7499892 | 16 |
| Cholesteryl ester transfer protein | CETP | rs9989419 | 16 |
| Endothelial lipase | LIPC | rs2000813 | 18 |
| Endothelial lipase | LIPC | rs4939883 | 18 |
| Hepatic lipase | LIPC | rs10468017 | 15 |
| Hepatic lipase | LIPC | rs1077834 | 15 |
| Hepatic lipase | LIPC | rs1532085 | 15 |
| Hepatic lipase | LIPC | rs1800588 | 15 |
| Hepatic lipase | LIPC | rs2070895 | 15 |
| Hepatic lipase | LIPC | rs4775041 | 15 |
| HMG-CoA Reductase | HMGCR | rs3846662 | 5 |
| Lipoprotein lipase | LPL | rs328 | 8 |
| Polypeptide N-acetylgalactosaminyltransferase 2 | GALNT2 | rs2144300 | 1 |
| Polypeptide N-acetylgalactosaminyltransferase 2 | GALNT2 | rs4846914 | 1 |
| Potassium channel tetramerization domain containing 10 | KCTD10 | rs2338104 | 12 |
| WW Domain Containing Oxidoreductase | WWOX | rs2548861 | 16 |
Fig. 1. Haplotype block organization of SNPs related to high-density lipoprotein cholesterol level on the LD maps for the Hungarian general (A) and Roma (B) populations. Linkage analyses were performed separately in the study populations. According to the LD map generated by Haploview, there are four haplotype blocks (outlined in a bold black line) consisting of variants that are in high LD. The blocks were formed by the SNPs of the \textit{CETP}, \textit{LIPC} and \textit{GALNT2} genes. The numbers above the map show the rs numbers of SNPs. The colour scheme is a standard Haploview colour scheme (white $D' = 1$ and LOD $= 2$, shades of pink/red: $D' < 1$ and LOD $= 2$, and bright red $D' = 1$ and LOD $\geq 2$). Numbers in squares are $D'$ values.

Table 2
Distribution of study populations by wGRS quintiles.

| Quintile of wGRS | Hungarian general population (%) | Hungarian Roma population (%) | p-value   |
|------------------|----------------------------------|------------------------------|-----------|
| 1st quintile     | 1.83                             | 0.51                         | 0.025     |
| 2nd quintile     | 17.18                            | 10.45                        | < 0.001   |
| 3rd quintile     | 48.38                            | 49.14                        | 0.756     |
| 4th quintile     | 30                               | 34.76                        | 0.037     |
| 5th quintile     | 2.61                             | 5.14                         | 0.004     |
Table 3
Output of multiple regression models using unweighted and weighted genetic risk scores as dependent variable and ethnicity, age and sex as independent variables.

| Dependent variable: GRS | Coefficient | p-value | β |
|-------------------------|-------------|---------|---|
| Ethnicity (Roma vs. General) | 0.667 | < 0.001 | 0.092 |
| Sex women vs. men) | 0.106 | 0.477 | 0.016 |
| Age | -0.0003 | 0.068 | -0.001 |

| Dependent variable: wGRS | Coefficient | p-value | β |
|-------------------------|-------------|---------|---|
| Ethnicity (Roma vs. General) | 0.029 | < 0.001 | 0.125 |
| Sex (women vs. men) | -0.001 | 0.774 | -0.006 |
| Age | -0.0002 | 0.202 | -0.028 |

β: relative strength of predictors

Multivariate regression analysis using age, sex as covariates did not change the inference neither for the GRS nor for wGRS.

Table 4
Proportion of subjects with reduced plasma HDL-C level in the General and Roma populations according to wGRS quintiles.

| 1st quintile of wGRS (0.15–0.30) | 2nd quintile of wGRS (0.31–0.45) | 3rd quintile of wGRS (0.46–0.59) | 4th quintile of wGRS (0.6–0.74) | 5th quintile of wGRS (0.75–0.88) | p-values for trend |
|----------------------------------|----------------------------------|----------------------------------|----------------------------------|----------------------------------|-------------------|
| **General (Men; Women)** | N = 26 (8;18) | N = 241 (115;126) | N = 681 (320;361) | N = 417 (200;217) | N = 36 (21;15) |
| Average HDL-C level (mmol/l) | 1.56 | 1.47 | 1.41 | 1.38 | 1.33 | 0.021 |
| Reduced plasma HDL-C (%) | 11.54 | 23.77 | 27.8 | 28.5 | 31.43 | 0.083 |
| **Roma (Men; Women)** | N = 3 (1;2) | N = 61 (28;33) | N = 287 (112;175) | N = 203 (76;127) | N = 30 (11;19) |
| Average HDL-C level (mmol/l) | 1.26 | 1.24 | 1.23 | 1.2 | 1.09 | 0.076 |
| Reduced plasma HDL-C (%) | 33.33 | 44.26 | 49.83 | 52.22 | 56.67 | 0.054 |

Table 5
Association of GRSs with plasma HDL-C level by study groups.

| GRS | Hungarian General | Hungarian Roma |
|-----|-------------------|----------------|
| β (95% CI) | p-value | β (95% CI) | p-value |
| GRS | | | |
| Model I | -0.01 (-0.018 to -0.003) | 0.004 | -0.013 (-0.023 to -0.003) | 0.011 |
| Model II | -0.011 (-0.018 to -0.004) | 0.003 | -0.013 (-0.023 to -0.003) | 0.009 |
| wGRS | | | |
| Model III | -0.243 (-0.466 to -0.020) | 0.033 | -0.318 (-0.633 to -0.002) | 0.049 |
| Model IV | -0.205 (-0.420 to 0.101) | 0.062 | -0.336 (-0.651 to -0.21) | 0.036 |

The association of GRS and wGRS with plasma HDL-C level were evaluated under unadjusted regression models (Model I and III) and under regression models adjusted for age and sex (Model II and IV) separately in Roma and general subjects. In all models the HDL-C was the dependent variable, the GRS/wGRS were the independent variables.

95% CI: 95% confidence interval

a HDL-C values were non-normally distributed and were transformed using a two-step approach suggested by Templeton [4].
Ethical approval

All procedures performed in studies involving human participants were in accordance with the ethical standards of the institutional and/or national research committee and with the 1964 Helsinki declaration and its later amendments or comparable ethical standards.

This study was approved by the Ethical Committee of the University of Debrecen, Medical Health Sciences Centre (Reference no. 2462-2006) and by the Ethical Committee of the Hungarian Scientific Council on Health (Reference nos. NKFP/1/0003/2005 and 8907-O/2011-EKU).

This article does not contain any studies with animals performed by any of the authors.
