Abstract: This paper investigates the mechanical properties of oriented polyvinyl chloride (PVC) nanofiber mats, which were obtained by electrospinning a PVC solution. PVC was dissolved in a solvent mixture of tetrahydrofuran/dimethylformamide. Electrospinning parameters used in our work were, voltage 20 kV; flow rate 0.5 mL/h; the distance between the syringe tip and collector was 15 cm. The rotating speed of the drum collector was varied from 500 to 2500 rpm with a range of 500 rpm. Nanofiber mats were characterized by scanning electron microscope, thermogravimetric analysis, differential scanning calorimetry methods. The mechanical properties of PVC nanofiber mats, such as tensile strength, Young’s modulus, thermal degradation, and glass transition temperature were also analyzed. It was shown that, by increasing the collector’s rotation speed from 0 (flat plate collector) to 2500 rpm (drum collector), the average diameter of PVC nanofibers decreased from 313 ± 52 to 229 ± 47 nm. At the same time, it was observed that the mechanical properties of the resulting nanofiber mats were improved: tensile strength increased from 2.2 ± 0.2 MPa to 9.1 ± 0.3 MPa, Young’s modulus from 53 ± 14 to 308 ± 19 MPa. Thermogravimetric analysis measurements showed that there was no difference in the process of thermal degradation of nanofiber mats and PVC powders. On the other hand, the glass transition temperature of nanofiber mats and powders did show different values, such values were 77.5 °C and 83.2 °C, respectively.

Keywords: nanofiber; electrospinning; PVC; mechanical properties; the orientation of nanofibers; nonwoven mats

1. Introduction

In order to consider polymer fibers as nanofibers, their diameter size must be in a range from a few nanometers to over 1000 nm [1]. Therefore, nanofibers present a large surface area to volume ratio, high porosity, high aspect ratio, small pore size, low density, and mass transfer properties [2,3]. Many methods currently exist to produce polymer nanofibers such as drawing, phase separation, template synthesis, freeze-drying synthesis, self-assembly, interfacial polymerization of nanofibers, and electrospinning. Nowadays, electrospinning is known to be one of the most efficient methods to fabricate nanofibers on an industrial scale [4]. Due to the many advantages that electrospun nanofibers present, they have been found to have many uses in different fields such as air filtration [5–8], antibacterial [9], oil/water separation [10,11], tissue engineering scaffolding [12,13], drug delivery [14–16], reinforced polymer composites [17], sensors [18,19], and others.

Although, nanofiber mats have many advantages over previously known fibers, nanofiber mats exhibit low mechanical properties, thereby limiting their applicability [20]. Many studies indicate that it is necessary to enhance the mechanical properties of nanofiber mats for their applications, due to their low mechanical properties such as tissue engineering [21] and filter media [22,23]. The low mechanical strength of the nanofiber mats can be explained for the following reasons: high porosity, randomly arranged nanofibers.
and weak interaction between the nanofibers cross-points [23]. To solve the problem of the mechanical strength of the nanofiber mats, many methods have been used such as the synthesis of nanofiber mats from polymer blends [22], thermal treatments, solvent-vapor methods to strengthen the junction between the nanofiber by cross-linking the nanofiber together [24,25], and the fabrication a highly oriented nanofiber mat [26]. From the methods described above, the fabrication of a nanofiber mat with high nanofiber orientation, showed to be an effective and simple method to increase mechanical strength. Therefore, to improve the mechanical strength of the nanofiber mats, it is necessary to have a high level of alignment nanofibers [27]. To obtain highly aligned nanofiber mats by electrospinning, different receivers such as auxiliary electrodes [28], disc collectors [29], rotating drum collectors [30] can be used. The use of a rotating drum collector allows the fabrication of nanofiber mats with a large area.

Polyvinyl chloride (PVC) is one of the most common materials, used in different fields due to its high applicability. However, PVC nanofibers are only found in a few areas. For example, PVC/polystyrene (PS) nanofibers were used for oil spill cleanup [31]. Alarifi et al. [32] have reported that nanofibers made from PVC mixed with polyvinylpyrrolidione (PVP), were used for water treatment. In addition, PVC nanofiber mats were used as a corrosion inhibitor for metals in NaCl [33]. Nevertheless, the common disadvantage of the resulting materials is their low mechanical properties. In order to increase the mechanical strength of nanofiber mats and expand their scope, it is necessary to increase the degree of orientation of the nanofibers in the mat [26,34,35]. PVC is the cheapest polymer that can be found on the market; it has many advantages, such as, high resistance to acids, alkalis, and corrosion. PVC nanofibers have the potential to be used for water filtration, air filtration, and anti-corrosion materials. However, research on strengthening PVC nanofibers, using a rotating drum collector, is lacking in the literature.

In this study, we produce nanofibers by using a rotating drum collector, varying its speed from 0 to 2500 rpm within an increasing range of 500 rpm. Analysis and evaluation of fibers orientation were done by a 2-D (two-dimensional) Fast Fourier transformation method using Photoshop and image software. The effect that different rotation speeds, of the rotating drum collector, have on nanofibers morphology, tensile strength, Young’s modulus, differential scanning calorimetry, and thermogravimetric properties was studied and analyzed. Additionally, the influence that different orientations and diameters of the nanofiber affected the mechanical properties of the nanofiber mats was evaluated.

2. Materials and Methods

2.1. Materials

Polyvinyl chloride powder used in this study was supplied by Klyokner Pentaplast Rus Ltd. (Saint Petersburg, Russian Federation) with the molecular weight of $M_w = 40,000$ Da. N,N-dimethylformamide (DMF) 99.9% was obtained from JSC EKOS-1 (Moscow, Russian Federation). Tetrahydrofuran (THF) 99.5% was purchased from Chemmed Ltd. (Moscow, Russian Federation). All reagents were used as received without further purification.

2.2. Fabrication of PVC Nanofibers

PVC solution was prepared by dissolving the PVC powder in the DMF/THF systems (ratio volume of 50/50) at a temperature of 50 °C and a stirring speed of 300 rpm with a 15% PVC weight concentration. Mixing was carried out for 3 h until the PVC dissolved completely. The prepared solution was kept at room temperature for 1 h, in order to remove air bubbles and for stabilization.

PVC nanofibers were spun using a Nanofiber Electrospinning System NANON-01A (MECC CO., LTD., Fukuoka, Japan) with a flat plate (length 200 mm, wide 150 mm) and rotating drum (diameter 200 mm, length 200 mm) collectors at room temperature (Figure 1). A 5-mL syringe and needle tip 18G (1 mm inner diameter) were used. The electrospinning parameters used in our work were voltage—20 kV; flow rate—0.5 mL/h; the distance between the syringe tip and collector was 15 cm. The rotating speed of the drum collector was
varied from 500 to 2500 rpm with a range of 500 rpm. For mechanical properties analysis, samples were collected after 10 hrs of electrospinning work. For morphology and scanning electron microscope (SEM) analysis, samples were obtained after 15 min of electrospinning work. Non-oriented fibers mats were obtained from a flat plate collector, oriented fibers mats were obtained from the drum collector. Before any studies or characterizations were done, all samples were kept at a temperature of 25 °C and relative humidity less than 75% for a period of 48 h.

Figure 1. Types of collectors: (a)—flat plate collector, (b)—rotating drum collector.

2.3. Methods

The SEM images were obtained using a Supra 40 SEM-FEG (Zeiss, Germany). Diameters of the electrospun PVC fibers were measured with an image analyzer (Image), National Institutes of Health, Bethesda, MD, USA. The average diameter of the nanofibers and the standard deviation were calculated based on measuring the diameter of 200 nanofibers selected randomly on three SEM images.

2-D Fast Fourier Transformation (FFT) was used for analysis of fiber orientation. In this method, the pixel intensity in an optical data image will be converted into a mathematically defined frequency domain [36]. Grayscale 8-bit images were cropped to 1000 × 1000 pixels for analysis. The used image-processing software ImageJ can apply the FFT rapidly to the photograph. Before performing an analysis of the orientation of the nanofiber mats, the contrast of the SEM images was increased with the tool “Curve” in Photoshop software. SEM images present a dark background, which can represent an obstacle when performing FFT analysis of nanofibers, mainly because some of the fibers are lost in the darkened areas. A color inversion was performed on the image, in which it is possible to see that the nanofibers are now black, and the background of the image is white. Convention is to place the 0° position at 12:00 o’clock on the unit circle and continue in a counterclockwise fashion with 90° at 9:00 o’clock, 180° at 6:00 o’clock, and 270° at 3:00 o’clock. The information obtained from the FFT photograph can be quantified by measuring the radial sum intensity for 360 radii around the center of the FFT photograph using the tool “Oval Profile” of “ImageJ” software. After processing, the graph will describe the orientation of the fibers. The resulting graph will have 4 peaks that occur every 90°; the 2 higher peaks will correspond to the angles 0° and 180°. A photograph with no alignment will show a constant pixel intensity absent of peaks, indicating no specific directionality. The FFT data were normalized to a baseline value of 0 and plots in arbitrary units from 0 to 0.1. To determine the orientation of the fibers, we followed the steps outlined above, repeating the process three times.

The tensile properties were measured by using an Instron 5943 tensile testing machine (Instron, USA). All samples were tested in accordance with the ISO 527-3 standard [37] at room temperature and a speed test of 50 mm/min. The sample sizes were 100 × 10 mm (length × wide). Measurements were performed at least five times, in order to determine tensile properties. The thickness of the test samples was measured by using a digital micrometer. Sample thickness is the mean value of the thickness measured at three different positions. In order to determine the tensile strength, the samples were divided in two groups. The first group was cut parallel to the direction of the nanofibers. The second group
was cut in a perpendicular direction to the direction of the nanofiber. Figure 2 shows the assembled apparatus for the electrospinning experiments, as well, a sample prepared for mechanical testing is shown.

**Figure 2.** Nanofiber mat obtained by electrospinning process: (a)—electrospinning system (1—rotating drum collector; 2—spinneret; 3—a syringe and a Teflon tube were used to supply the solutions); (b)—sample for tensile testing.

Thermogravimetric analysis (TGA) was performed, by using a TG 209 F1 Libra (Netzsch, Germany) under a nitrogen atmosphere with a flow rate of 40 mL/min. The samples were studied on a range of temperatures that went from 25 °C to 900 °C with an increasing rate of 10 °C/min. Differential scanning calorimetry (DSC) studies were performed, by using a DSC 204 F1 Phoenix (Netzsch, Germany) under a nitrogen atmosphere with a flow rate of 20 mL/min. The samples were heated from −65 °C to 250 °C with an increasing rate of 10 °C/min.

3. Results and Discussion

Figure 3 shows PVC nanofibers’ SEM images and the nanofiber mats photoshopped photos for alignment analysis and directional analysis. As can be observed from the SEM images, not only are the fibers pulled during electrospinning, but droplets also are formed during the electrospinning process. Through image processing, the directional distribution of the fibers becomes clear, which makes the FFT method applied for the analysis easier.

![Figure 3](image)

**Figure 3.** SEM image of polyvinyl chloride (PVC) nanofibers: (a)—before processing; (b)—after processing.
Figure 4 shows diagrams of nanofibers’ diameter distribution. The skew of nanofibers’ sample diameter distribution collected at different speeds (|A|) is less than 0.5; thus, it is possible to use Gaussian distribution. Table 1 shows the average diameter of the obtained fibers. An increase in the rotational speed of the drum leads to a decrease in the average diameter of the nanofiber while the other parameters remain unchanged. The average diameter of the nanofibers decreases from $313 \pm 52$ nm to $229 \pm 47$ nm with an increase in the drum collector’s rotation speed from 0 rpm to 2500 rpm. The value of the standard deviation of the average diameter of the nanofibers remains almost constant. The decrease in the average diameter of the nanofibers is due to an increase in the speed of the rotating drum collector.

Figure 4. Diameter distribution of PVC nanofibers with different drum rotation speeds: (a)—0 rpm (flat plate collector); (b)—500 rpm; (c)—1000 rpm; (d)—1500 rpm; (e)—2000 rpm; (f)—2500 rpm.
Table 1. The dependence of the mean nanofiber diameter on the rotation speed of the collector.

| Rotation Speed, rpm | 0 (Flat Plate Collector) | 500 | 1000 | 1500 | 2000 | 2500 |
|---------------------|--------------------------|-----|------|------|------|------|
| Mean nanofiber diameter, nm | 313 | 302 | 280 | 272 | 256 | 229 |
| Standard deviation (σ), nm | 52 | 46 | 43 | 47 | 39 | 47 |

Figure 5 shows the results of the alignment analysis of nanofiber with different speeds of the rotating drum collector. The analysis results show that, when increasing the drum’s rotation speed from 0 to 500, 1000, 1500, 2000 and 2500, the FFT Alignment (normalized) value increases from 0.031 to 0.035, 0.066, 0.073, 0.095 and 0.1, respectively. When using a flat plate collector, the nanofibers lie randomly. An increase in FFT Alignment values indicates the formation of orientated nanofibers in the mats. When the rotation speed is greater than 1000 rpm the value of FFT alignment peaks is greater than 0.065, this demonstrates the potential to obtain aligned nanofibers, by increasing the drum collector’s rotation speed. Therefore, an increase in the drum collector’s rotation speed leads to the stabilization of the drawing process and a decrease in the number of droplets formed. SEM images revealed that, by increasing the rotation speed, the orientation of the obtained fibers also increases [38].

Figure 5. Alignment analysis and directional analysis: 1—0 rpm (flat plate collector); 2—500 rpm; 3—1000 rpm; 4—1500 rpm; 5—2000 rpm; 6—2500 rpm.

The stress–strain diagrams of PVC nanofiber mats obtained from different rotational speeds are shown in Figure 6 and Table 2. From the stress–strain diagrams of PVC nanofiber mats, it is easy to notice that nanofiber mats obtained at a high rotation speed have more durability. In this work it was demonstrated that an increase in the drum collector’s rotation speed leads to an increase in the mechanical strength of the nanofiber mats. Tensile strength increases from 2.2 ± 0.2 MPa to 9.1 ± 0.3 MPa and the Young’s modulus from 53 ± 14 MPa to 308 ± 19 MPa, respectively, with an increase in rotation speed from 0 to 2500 rpm. The change in elongation at break of the film is not very noticeable, with respect to the change in the drum collector’s rotation speed, exhibiting an amount of about 30%. Due to nanofiber entanglement in the mat, the value of the elongation at break is very small, which makes it almost unchangeable. Carrizales et al. [39] have reported that PVC nanofiber has a tensile strength of 2.2 ± 0.2 MPa and a modulus 12.3 ± 2.6 MPa. These results are similar to the result we obtained from the sample at 0 rpm. The improvement of
the nanofibers mats’ mechanical properties can be explained by several reasons, which are going to be described below.

![Figure 6. PVC nanofibers stress–strain diagrams, with rotation speeds of the collector at 1000 rpm.](image)

**Table 2.** Mechanical properties of PVC nanofiber mats with parallel orientated nanofiber.

| Rotation Speed (rpm) | The Thickness of Nanofiber Mats (µm) | Tensile Strength, \(\sigma_{\text{at break}}\) (MPa) | Young’s Modulus, \(E\) (MPa) | Elongation at Break, \(\varepsilon_{\text{at break}}\) (%) |
|---------------------|--------------------------------------|-----------------------------------------------|-----------------------------|-----------------------------------------------|
| 0                   | 73 ± 10                              | 2.2 ± 0.2                                     | 53 ± 14                     | 26 ± 3                                        |
| 500                 | 33 ± 3                               | 3.0 ± 0.3                                     | 64 ± 13                     | 31 ± 7                                        |
| 1000                | 33 ± 3                               | 5.7 ± 0.3                                     | 147 ± 28                    | 30 ± 4                                        |
| 1500                | 25 ± 2                               | 5.2 ± 0.4                                     | 150 ± 17                    | 28 ± 5                                        |
| 2000                | 31 ± 2                               | 6.1 ± 0.6                                     | 175 ± 19                    | 24 ± 7                                        |
| 2500                | 20 ± 2                               | 9.1 ± 0.3                                     | 308 ± 19                    | 30 ± 4                                        |

Firstly, the anisotropy mechanical is a major factor that affects the mechanical properties of the nanofiber mats. When the nanofibers are randomly distributed, the strength of the mat is lower than that of oriented nanofibers. Moreover, when the drum collector’s rotation speed is greater than 1000 rpm, the obtained nanofibers exhibited a better alignment orientation [40,41]. The orientation of the nanofibers increases the strength of the nanofiber mats. Specifically, we can observe this improvement by comparing the mats obtained at 500 rpm, with tensile strength and Young’s modulus of 3.0 ± 0.3 MPa and 64 ± 13 MPa, respectively, with the mat obtained at 1000 rpm which has a tensile strength and Young’s modulus was 5.7 ± 0.3 MPa and 147 ± 28 MPa, respectively.

Secondly, several studies reported that a decrease in fiber diameter of approximately 700 nm leads to a change in tensile modulus and strength modulus. This change becomes even more pronounced when the diameter of the nanofiber is below 700 nm. Nanofiber-based studies have shown that as the fiber diameter decreases to a critical value, the mechanical properties increase exponentially. When the diameter of the nanofiber is entangled between molecules, the structure of nanofiber will present fewer defects and a more uniform structure, leading to higher durability [42–44]. Therefore, the increase in the durability of nanofiber mats can be explained by the decrease in nanofiber diameter, which goes from 313 ± 52 nm to 219 ± 47 nm.

Thirdly, the tensile stress of the nanofiber mats depends on many factors, such as the chemical structure of the polymer, the molecular orientation, and the extension chain of the polymer. PVC is an amorphous polymer. The random or orderly arrangement of the amorphous phase determines the physical and mechanical properties of the nanofibers [45]. In the process of electrospinning under the action of electromagnetic forces, the polymer molecules are pulled out creating an orientation in the polymer molecule. The use of a
rotating drum collector with a higher rotation speed results in a more directed pull of the mechanical force on the polymer molecule. This increases the strength of nanofiber mats. In summary, the increase in tensile strength and tensile modulus is due to the alignment of nanofibers in the mats, the decrease in fiber diameter, and molecular orientation in the amorphous phase of polymer.

Table 3 shows the mechanical properties of nanofiber mats with perpendicularly oriented nanofibers. Comparing with the properties of nanofibers with a parallel orientation, it is easy to observe that there is not a considerable difference when the rotating speed of the drum is 500 and when using the plate static collector. While using a static collector, the nanofibers are randomly distributed, so there is not a visible effect on the strength of the nanofiber mat. As the rotational speed of the drum increased from 1000 to 2500, it was possible to observe a marked difference in the strength between the parallel and perpendicular orientated nanofibers. This proves that the orientations of the nanofiber has a direct effect on the durability of nanofiber mats; hence, when the orientation of fibers increases, the strength of nanofiber mats increases as well. In addition, it is possible to notice that the elongation at break increased for those samples with perpendicular orientated nanofibers.

Table 3. Mechanical properties of PVC nanofiber mats with perpendicular orientation nanofibers.

| Rotation Speed (rpm) | Tensile Strength, $\sigma_{\text{at break}}$ (MPa) | Young’s Modulus, $E$ (MPa) | Elongation at Break, $\varepsilon_{\text{at break}}$ (%) |
|----------------------|---------------------------------|-----------------|-----------------|
| 0                    | 2.1 ± 0.1                       | 60 ± 15         | 63 ± 6          |
| 500                  | 2.0 ± 0.6                       | 48 ± 9          | 74 ± 8          |
| 1000                 | 0.9 ± 0.1                       | 20 ± 6          | 66 ± 8          |
| 1500                 | 1.0 ± 0.1                       | 11 ± 4          | 80 ± 16         |
| 2000                 | 0.9 ± 0.3                       | 23 ± 4          | 100 ± 8         |
| 2500                 | 0.9 ± 0.3                       | 17 ± 4          | 105 ± 10        |

Figure 7 shows the plots of tensile strength and Young’s modulus, versus the FFT alignment value. The graphs show that with an increase in the FFT alignment value of the nanofiber in the mat, the mechanical properties of the mats increased for those mats with a parallel oriented nanofiber. This effect can be explained as a result of an increase in the degree of the orientation of nanofibers and PVC molecules inside the fiber. However, for samples with a perpendicular fiber arrangement, tensile strength and Young’s modulus did not present a considerable change. Therefore, the change in fiber orientation is the main cause that leads to the change in the tensile strength and Young’s modulus of the nanofiber mats.

**Figure 7.** The dependence of mechanical properties on Fast Fourier Transformation (FFT) alignment value: (a)—nanofibers oriented in a parallel direction; (b)—nanofibers oriented in a perpendicular direction.
The results of the TGA analysis showed that the TGA curve for the initial PVC granules and the nanofiber mats is the same and has two stages of thermal degradation (Figure 8). The first stage of thermal degradation starts at 233 °C and the second stage starts at 320 °C. The thermal degradation of PVC nanofibers proceeds in the same way as, for PVC powder. The results showed that PVC powder and PVC nanofiber presented three degradation steps, in which PVC nanofibers lost less volume at each step [39]. The thermal degradation values for PVC nanofiber mats samples obtained from different rotation speeds were the same.

Figure 8. Thermograms for PVC: 1—0 rpm; 2—500 rpm; 3—1000 rpm; 4—1500 rpm; 5—2000 rpm; 6—2500 rpm; 7—PVC powder.

Figure 9 shows the result of the DSC analysis. For PVC powder the glass transition temperature (T_g) is 83.2 °C, and that for the PVC nanofiber mats is 77.5 °C. PVC nanofiber mats have a lower glass transition temperature than PVC powders. A decrease in the glass transition temperature may be associated with a decrease in the size of the diameter of the fibers with respect to the dimensions of the volumetric PVC [46]. Table 4 shows that the glass transition temperatures of PVC nanofibers obtained by electrospinning at different rotational speeds of the drum collector are the same.

Figure 9. Differential scanning calorimetry (DSC) thermogram of PVC: 1—0 rpm; 2—500 rpm; 3—1000 rpm; 4—1500 rpm; 5—2000 rpm; 6—2500 rpm; 7—PVC powder.
Table 4. Glass transition temperature (Tg) of PVC nanofibers and PVC powder.

| Materials PVC Powder | PVC Nanofiber Mats Obtained By Electrospinning At Different Rotational Speeds |
|---------------------|--------------------------------------------------------------------------|
|                     | 0 (Flat Plate Collector) | 500 | 1000 | 1500 | 2000 | 2500 |
| The glass transition temperature (Tg), °C | 83.2 | 77.9 | 77.5 | 77.9 | 76.8 | 77.4 | 77.5 |

4. Conclusions

Fiber morphology, which includes the orientation of the nanofiber mat and individual characteristics of the nanofiber, are the main factors that affect the mechanical properties of the nanofiber mats. Therefore, to improve the mechanical properties of the nanofiber mats, it is necessary to improve the morphology and change the individual characteristics of the nanofiber in the mats. In this study, we were able to change the morphology of the nanofibers, by using a rotating drum collector. Oriented PVC nanofibers were obtained by electrospinning at a rotational speed of the drum collector from 0 to 2500 rpm. Based on SEM images, the diameter of the nanofibers varied from 313 ± 52 to 229 ± 47 nm, in relation to the increase in the collector’s rotation speed, from 0 to 2500 rpm. Additionally, the tensile strength increased from 2.2 ± 0.2 MPa to 9.1 ± 0.3 MPa, the Young’s modulus from 53 ± 14 to 308 ± 19 MPa. Moreover, we found that the change in fiber orientation is the main cause that leads to the change in the mechanical properties of the nanofiber mats. Furthermore, it was shown that an increase in the rotation speed of the collector leads to an increase in the degree of orientation of PVC nanofibers and an increase in mechanical properties. DSC measurements showed that the glass transition temperature of nanofibers is lower than that of powders PVC.

Author Contributions: Conceptualization, M.V.U.; formal analysis, Q.P.L., R.O.O.; investigation, Q.P.L., R.O.O., M.A.B.; resources M.V.U.; writing—original draft preparation, writing—review and editing, Q.P.L., R.O.O.; supervision, M.V.U.; funding acquisition, M.V.U. All authors have read and agreed to the published version of the manuscript.

Funding: This work was financially supported by the Government of Russian Federation (Grant 08-08).

Institutional Review Board Statement: Not applicable.

Informed Consent Statement: Not applicable.

Data Availability Statement: Data sharing not applicable to this article as no datasets were generated or analysed during the current study.

Conflicts of Interest: The authors declared that they have no conflict of interest in this work.
