Effect of NPK Water-soluble Fertilizer on Growth, Yield and Nutrient Uptake of Finger Millet

N. Senthilkumar, G. Gokul

ABSTRACT

Background: The availability of macro and micronutrients added to the soil are affected by soil environmental factors leading to various losses. When a similar amount of fertilizer is applied through foliar application, its use efficiency is increased many folds. In the sandy loam soil, foliar applied fertilizers are up to 20 times more effective as compared to soil applied fertilizers. Water soluble fertilizer of 19:19:19 grade N: P: K is totally water soluble and present in crystalline powder form. It can be applied to the crop by fertigation or through foliar spraying. Instant uptake of nutrients by the plants resulting in significant and quick improvement in crop growth. Humic acid when applied to field converted into readily available humic substances which directly or indirectly effect the plant growth. Foliar application of nutrients along with soil application of nutrients increase the yield and to improve the quality of cereal crops. Keeping the aforesaid facts in consideration, the present investigation was carried out to study effect of NPK water soluble fertilizer on growth, yield and yield attributes and nutrient uptake of ragi.

Methods: The present investigation was carried out during January – May 2018 at farmers field, kamaraipuram village, Katpadi Taluk, Vellore district, Tamil Nadu, India. The experiments were laid out in RBD (Randomized Block Design), Ragi [Elusine coracana (L.) Gaertn], CO-14 variety were taken into study. The experimental soil was sandy loam, 10 treatments with replicated thrice. The soil and plant sample was collected periodically proceed with standard analytical and statistical method followed.

Result: Our investigations the soil and foliar feeding of nutrients along with water soluble fertilizer and humic acid combined treatment T_{10} (Soil application of 50% RDN + foliar spray of 50% RDN and 100% P and K through water soluble fertilizer on 20 and 40 DAT) + foliar spray of humic acid 0.1% (on 20 and 40 DAT) was significantly superior in performance with respect to growth, yield attributes, quality and nutrient uptake by ragi. It can be recommended to farmers to achieve more benefit from finger millet.

Key words: Growth, Humic acid, Nutrient uptake, Water soluble fertilizer, Yield.

INTRODUCTION

Finger millet [Elusine coracana (L.) Gaertn] is one of the important millet crops in India. The cultivated area of ragi in India is 1.02 million ha (m ha) and production is 1.38 million tonnes with an average productivity of 1.4 t ha⁻¹. The major ragi growing states in India are Karnataka, Tamil Nadu, Andhra Pradesh, Orissa, Jharkhand, Maharashtra and Uttaranchal. In Tamil Nadu, ragi is the most important traditional millet crop grown in an area of 0.06 m ha with production of 0.11 million tonnes and the productivity of 1.9 t ha⁻¹ that provides food and nutritional security to the marginal farmers in the rain fed dry lands and hilly tribal areas (India Stat, 2017).

The availability of macro and micronutrients added to the soil are affected by soil environmental factors leading to various losses. When a similar amount of fertilizer is applied through foliar application, its use efficiency is increased many folds. In the sandy loam soil, foliar applied fertilizers are up to 20 times more effective as compared to soil applied fertilizers. Arif et al. (2006) found that based on soil properties, foliar spraying could be effective 6 to 20 times as compared to soil application. Foliar application could be an advantage for crop growth (Seifi Nadergholi et al., 2011). However, acute nutrient deficiencies can often be identified and corrected more rapidly via foliar fertilization than slower-uptake soil amendments (Erica Strauss, 2014).

Water soluble fertilizer of 19:19:19 grade N:P:K is totally water soluble and present in crystalline powder form. It can be applied to the crop by fertigation or through foliar spraying. Instant uptake of nutrients by the plants resulting in significant and quick improvement in crop growth (SPIC Triumph, 2019). Humic acid when applied to field converted into readily available humic substances which directly or indirectly effect the plant growth (Buyukkeskin and Akinci, 2011). Addition of humic acid reduces the requirement of primary macronutrients (NPK) at optimal growth (Daur and Bakhshaewain, 2013). Application of humic acid along with inorganic fertilizer increases the efficiency of inorganic
fertilizer which in turn aids to reduce its rate without disturbing the yield crop (Han, 2011). Foliar application of nutrients along with soil application of nutrients increase the yield and to improve the quality of cereal crops (Zafar Jamal et al., 2007). Keeping the aforesaid facts in consideration, the present investigation was carried out to study effect of NPK water soluble fertilizer on growth, yield and yield attributes and nutrient uptake of ragi.

MATERIALS AND METHODS
The present investigation was carried out during January – May 2018 at farmers field, kamarajapuram village, Katpadi Taluk, Vellore district, Tamil Nadu, India. The experiments were laid out in RBD (Randomized Block Design), Ragi [Elusine coracana (L.) Gaertn], CO-14 variety were taken into study. The experimental soil was sandy loam with a pH of 7.83, EC of 0.26 dSm$^{-1}$ and CEC of 12.50 cmol (p+) kg$^{-1}$. The available nitrogen, phosphorus, potassium and sulphur contents were 270.60, 12.57, 256.20 kg ha$^{-1}$ and 13.12 mg kg$^{-1}$ respectively. The experiment consist of ten treatments (T1 - Absolute control, T2 - Soil application of 100% RDF, T3 - Soil application of 50% RDF, T4 - Foliar spray of 100% RDF through water soluble fertilizer (FS on 20 and 40 DAT), T5 - Soil application of 50% RDN + foliar spray of 50% RDN and 100% PandK through water soluble fertilizer (FS on 20 and 40 DAT), T6 - Foliar spray of humic acid 0.1% (FS on 20 and 40 DAT), T7 - Foliar spray of humic acid 1.0% (FS on 20 and 40 DAT), T8 - Foliar spray of humic acid 0.1% (FS on 20 and 40 DAT), T9 - Foliar spray of humic acid 0.1% (FS on 20 and 40 DAT) of 50% RDN and P and K through water soluble fertilizer (foliar spray 20 and 40 DAT) + foliar spray of humic acid 0.1% (on 20 and 40 DAT) and T10 - Foliar spray of humic acid 0.1% (FS on 20 and 40 DAT) replicated thrice. Primary tillage was done by disc plough followed by passing cultivator twice, harrowed and levelled to get required seed bed.

The entire dose of N, P, K, and K$_2$O were applied as basal. Foliar application of water soluble fertilizer and humic acid 0.1 per cent on 20 and 40 DAT was applied as per the treatment. The grain and straw yield were recorded at harvest and analysed for the content of N, P, K and S using the standard procedure. The concentration of nutrients was converted into uptake by multiplying the yield with concentration.

RESULTS AND DISCUSSION
Growth parameters
Significantly higher plant height (122.9 cm), number of tillers (9.4) and dry matter production (12806.5 kg ha$^{-1}$) at harvest stage were recorded with soil application of 50% RDN + foliar spray of 50% RDN and P and K through water soluble fertilizer (on 20 and 40 DAT) + foliar spray of humic acid 0.1% (on 20 and 40 DAT) (T1) followed by soil application of 50% RDN + foliar spray of 50% RDN and 100% P and K through water soluble fertilizer (on 20 and 40 DAT) (T3), T5, T7, T9, T10 and T12 respectively.

The cumulative and conjunctive application of soil and foliar feeding of balanced nutrients to the crop might have enjoyed with sufficient nutrient condition for a longer period of time and thereby allowing the plant to perpetuate with plant height. Findings of this investigation are in close conformity with those of Reddy et al. (2018), who reported significantly highest plant height in finger millet through 2% urea spray which was at par with 2% 19:19:19 spray. Similar findings were also observed by Rajesh (2011) and Mukund et al. (2014) in pigeon pea.

Foliar application of humic acid treatment recorded the highest plant height was obtained from the treatment of leaves (100%) gave a significantly higher plant height than the control and other treatments in common millet (Veyssel et al., 2011). The findings are in conformity with the work of Define et al. (2005) in black gram, Patil et al. (2008) in green gram. Han (2011) reported that application of humic acid along with inorganic fertilizer increases the efficiency of inorganic fertilizer which improves the plant growth parameters of crop.

Yield components
The yield parameters like number of fingers, earhead length, number of fingers ear head$^{-1}$ and thousand grain weight, straw yield and grain yield are significantly influenced by soil and foliar application of water soluble fertilizer and humic acid (Table 2). The results indicated significant increase in the number of ear plant$^{-1}$ (6.7), earhead length (10.74 cm), number of fingers ear head$^{-1}$ (8.7) thousand grain weight (3.0 gm), straw yield (8206.8 kg ha$^{-1}$) and grain yield (3376.7 kg ha$^{-1}$) with soil application of 50% RDN + foliar spray of 50% RDN and P and K through water soluble fertilizer (foliar spray 20 and 40 DAT) + foliar spray of humic acid 0.1% (on 20 and 40 DAT) (T10) over rest of the treatments.

Similar effect of foliar feeding techniques of water soluble fertilizers of plant nutrients on crop production was earlier reported by Srinivas and Sundari (2004) in black gram, Mallesha et al. (2014) in red gram and Das and Jana (2015) in green gram, Rahman et al. (2014) in wheat and Reddy et al. (2018) in finger millet.

Improved yield and growth attributes might be interpreted as the manifestation of higher nutrients uptake.

| T$_{10}$          | 109.97                           | 63.45                             | 9.68                             | 32.10                           |
| CD (P=0.05)       | 4.56                             | 3.24                             | 0.48                             | 1.92                            |

by the plants. Nitrogen being a structural component of proteins involved in various biological functions. Whereas, phosphorous involved in better development of root systems and enhance the efficiency of nutrient and water uptake by roots. Potassium imparts resistance to major biotic and abiotic stress.

**Nutrient uptake**

The soil application of 50% RDF + foliar spray of 50% RDF and 100% P and K through water soluble fertilizer, (foliar spray 20 and 40 DAT) + foliar spray of humic acid 0.1% (foliar spray 20 and 40 DAT) (T$_{10}$) recorded significantly higher uptake of N, P and K as compared to other treatments. The treatments receiving soil application of 100 % RDF + foliar spray of WSF at two stages, recorded significantly higher uptake of N, P and K as compare to other treatments. Similar findings were reported by other researchers (Senthil and Kumaresan, 2006; Kalaimani, 2014). Babu (2017) reported that increased dose of RDF along with foliar application of humic acid gradually increased the NPK uptake of black gram. The stimulatory effects of humic substances have been directly correlated with the enhanced uptake of macro nutrients, such as nitrogen, phosphorus and sulphur and micro nutrients such as Fe, Zn, Cu and Mn(Chen et al., 1999). The findings are in conformity with the work of Ayman et al. (2009) in bean, Khaled and Fawy (2011) in corn and Du et al. (2013) in pearl millet.

**CONCLUSION**

The soil and foliar feeding of nutrients along with water soluble fertilizer and humic acid combined treatment T$_{10}$ (Soil application of 50% RDF + foliar spray of 50% RDF and 100% P and K through water soluble fertilizer [on 20 and 40 DAT] + foliar spray of humic acid 0.1% [on 20 and 40 DAT]) was significantly superior in performance with respect to growth, yield attributes, quality and nutrient uptake by ragi. It can be recommended to farmers to achieve more benefit from finger millet.
