THE LANDSCAPE LAW FOR THE INTEGRATED DENSITY OF STATES

G. DAVID, M. FILOCHE, AND S. MAYBORODA.

Abstract. The present paper establishes non-asymptotic estimates from above and below on the integrated density of states of the Schrödinger operator $L = -\Delta + V$, using a counting function for the minima of the localization landscape, a solution to the equation $Lu = 1$.

Résumé en Français. Dans cet article on établit des bornes inférieures et supérieures sur la densité d’états intégrée pour l’opérateur de Schrödinger $L = -\Delta + V$, à l’aide d’une fonction comptant les minima de la fonction paysage, la solution de $Lu = 1$ avec des conditions au bord adaptées. Contexte des potentiels désordonnés on en déduit les meilleures estimations connues sur la densité d’états intégrée dans le modèle d’Anderson sur $\mathbb{R}^d$.

1. Introduction

The density of states of the Schrödinger operator $-\Delta + V$ is one of the main characteristics defining the physical properties of the matter. At this point, most of the known estimates for the integrated density of states pertain to two asymptotic regimes, each carrying restrictions on the underlying potentials. The first one stems from the Weyl law and its improved version due to the Fefferman-Phong uncertainty principle [F]. It addresses the energies or eigenvalues $\lambda \to +\infty$ and deteriorates for the potentials oscillating at a wide range of scales. The second one concentrates on the asymptotics as $\lambda$ tends to 0 for disordered potentials, the so-called Lifschitz tails, and takes advantage of probabilistic arguments and the random nature of the disordered potentials. The goal of the present paper is to establish new bounds on the integrated density of states via the counting function of the so-called localization landscape [FM2]. The main theorem can be viewed as
a new version of the uncertainty principle, which, contrary to the above, applies uniformly across the entire spectrum and covers all potentials bounded from below irrespectively of their nature.

To set the stage, let us consider the spectrum of the Schrödinger operator \( L = -\Delta + V \) on a domain \( \Omega \subset \mathbb{R}^d \). We shall assume for the time being that \( \Omega \) is a cube in \( \mathbb{R}^d \) of sidelength \( R_0 \in \mathbb{N} \) and make sure that the estimates that we seek do not depend on the size of the domain, so that we can pass to the limit of infinite domain whenever it is desired and appropriate.

Assume furthermore that \( V \) is a bounded non-negative function on \( \Omega \) and \( L = -\Delta + V \) (once again, the boundedness assumption on \( V \) is, at this point, cosmetic: the resulting estimates do not depend on the maximum value and we can include more general potentials into consideration). We denote by \( N \) the (normalized) integrated density of states of the operator \( L \) with periodic boundary conditions on \( \partial \Omega \), i.e.,

\[
N(\mu) := \frac{1}{|\Omega|} \times \{ \text{the number of eigenvalues } \lambda \text{ such that } \lambda \leq \mu \}.
\]

As usual, eigenvalues are counted with multiplicity. It is known that the operator \( L \) above, with periodic boundary conditions on \( \partial \Omega \), has a discrete spectrum consisting of positive eigenvalues and hence, the definition is coherent.

In 1911, Hermann Weyl proposed what became later known as the Weyl law for the asymptotics of \( N(\mu) \), as \( \mu \to +\infty \), for the Laplace-Beltrami operator with the Dirichlet boundary conditions in a bounded domain. In his setting, the law gives an asymptotic of a multiple of \( \mu^{d/2} \) as \( \mu \to +\infty \). Perhaps much more importantly than the result itself, it gave a general approach to the asymptotics of the density of states of an elliptic operator, and in particular, the rule of thumb traditionally used in physics is

\[
N(\mu) \sim \frac{1}{(2\pi)^d|\Omega|} \int_{|g|^2 + V(x) < \mu} dx d\xi, \quad \text{as } \mu \to \infty.
\]

It is simultaneously impossible to list all the directions in which the Weyl law has been extended over the years and to give a sharp class of \( V \) to which it applies, with nice control of the asymptotic errors. However, the oscillations of \( V \) at the scales smaller than \( \mu^{-1/2} \) can easily destroy the validity of the volume-counting (1.2) for the corresponding \( \mu \). In fact, the Weyl law prediction (1.2) fails even for systems as simple as two uncoupled harmonic oscillators, that is, the potential \( V(x_1, x_2) = x_1^2 + \varepsilon x_2^2 \) with a small \( \varepsilon \) (see, e.g., [F], p. 143).

An obvious shortcoming of the “classical” Weyl law is the emphasis on the volume counting itself, as an eigenfunction cannot occupy an arbitrarily shaped volume in the phase space. This issue has been alleviated with the celebrated Uncertainty Principle of Fefferman and Phong ultimately reaching out to the problem

\footnote{The estimate from above is due to Cwickel, Lieb and Rosenblum [S79].}
of stability of matter \cite{F}. Instead of the volume-counting of (1.2), Fefferman and Phong suggested to estimate the number of disjoint cubes with sidelength $\mu^{-1/2}$ and such that $\left(\int_0^1 |V|^p \, dx\right)^{1/p} \leq C \mu$, smoothing the oscillations of $V$ at the correct scales. The resulting bounds on $N(\mu)$ were proved when $V$ is a polynomial and $p = \infty$ in \cite{F} and for $V \geq 0$ in a suitable reverse Hölder case by Shen \cite{S1, S2}, and were also extended to estimates on a number of negative eigenvalues for general $V \leq 0$. Overall, these ideas have brought a number of fascinating results – their goals and achievements, stemming from a new diagonalization of pseudodifferential operators, are beyond the scope of our review. But in the particular context of interest in this paper, they also fall short in some respects. First, searching for the aforementioned collection of optimal cubes for every $\mu$ can be computationally very challenging. Secondly, and this is exactly the reason for the restrictions on the potential and/or asymptotic nature of the results, the sharp estimates from above and below for positive potentials are only available when $V$ behaves not too violently at the corresponding scales. This rends them formally inapplicable for the Anderson or other disordered potentials, and more generally whenever $V$ is very different from its average on a cube. The Landscape Law proposed in this paper addresses both of these issues. The landscape “determines” the correct cubes and exhibits precisely the correct oscillation, in some sense creating a perfect effective potential for the Fefferman-Phong-type counting from any initial $V$.

above which would be desirably close to the estimate from below is challenging and requires different techniques.

landscape, which yielded astonishingly precise non-asymptotic estimates on the density of states for both periodic and certain Anderson-type potentials throughout multiple numerical and physical experiments \cite{FM2, ADFJM2, ADFJM3}. However, so far no rigorous mathematical results have supported these findings and, in particular, it was not clear what are the exact bounds, what is the range of potentials to which the theory could be applied, whether the results are generic or governed by the particular choice of examples, whether one can truly furnish localization landscape theory in the context of Anderson localization. In the present paper we prove that a counting function arising from the landscape provides sharp estimates from above and below on the density of states for any non-negative potential in the Schrödinger operator. As a by-product, we derive new estimates on the integrated density of states for the Anderson-type potentials. However, the latter is only a particular instance of our theory – our main results are deterministic.

The concept of localization landscape was pioneered by the second and third authors of the present paper in \cite{FM2}. The landscape is the solution to $(-\Delta + V) u = 1$, with the same boundary conditions as the original operator in question. When applied to the Laplacian rather than the Schrödinger operator and equipped with the Dirichlet boundary conditions, the landscape is nothing else than the classical
torsion function, however, its role in our theory and its character in the presence of a potential are very different, and we will continue using the landscape terminology which seems to be more illustrative under the circumstances.

First numerical [ADFJM3] and then rigorous mathematical results [ADFJM1] have demonstrated the relationship between the landscape and the location and shape of localized eigenfunctions, including the pattern of their exponential decay. One of the key observations underpinning these works is that the operator $L = -\Delta + V$ has exactly the same spectrum as a conjugated operator 

$$\frac{-1}{u^2} \text{div} u^2 \nabla + \frac{1}{u}$$

which brings up $1/u$ as an effective potential. This is a consequence of the identity

(1.3) \[ \int |\nabla f|^2 + V f^2 \, dx = \int u^2 \left| \nabla \left( \frac{f}{u} \right) \right|^2 + \frac{1}{u} f^2 \, dx, \]

valid for all $f$ in the corresponding Sobolev space $W^{1,2}(\Omega)$ and proved in [ADFJM1]. However, not only $1/u$ plays the role of a potential, but it exhibits decisively better properties than the original $V$. The reduced kinetic energy, which is the first term on the right-hand side of (1.3), is small in many typical examples, at least at the bottom of the spectrum, and hence $1/u$ “absorbs” the information about both kinetic and potential energy of the original system, in some sense, yielding a stronger form of the Uncertainty Principle than those discussed above.

Motivated by these considerations, we were led to investigate the information about the spectrum of $L$ encoded in $1/u$, and the numerical experiments brought surprising results, in fact, exceeding original expectations [ADFJM3, ADFJM2]. In generic samples of Anderson-type potentials in finite one- and two-dimensional domains one could observe two strongly emerging patterns. First, the eigenvalues at the bottom of the spectrum are essentially dimensional multiples of local minima of $1/u$. That is, independently of the potential, we observe an almost equality

(1.4) \[ \left( 1 + \frac{d}{4} \right) \left( \min \frac{1}{u} \right) \sim \lambda_j \]

where the eigenvalues and minima are indexed in nondecreasing order. Secondly, a version of the Weyl law governed by the potential $1/u$

(1.5) \[ N(\mu) \sim \frac{1}{(2\pi)^d|\Omega|} \int_{\left| \xi \right|^2 + \frac{1}{u^2} < \mu} \, dxd\xi \]

yields, contrary to (1.2), an approximation of the density of states throughout the spectrum, for all values of $\mu$, albeit working a little worse than minima (1.4) at the very bottom. Figure 1, taken from [ADFJM2], shows the advantage of using the landscape rather than the original $V$ in the predictor (1.5).
Both observations have been immediately adopted by physicists, for Schrödinger and Poisson-Schrödinger (Hartree-Fock) systems [FP+, PL+, CKOOS, TM+], and for Dirac equation [LP+]; however, even rigorous mathematical conjectures remained beyond reach, particularly if aiming for non-asymptotic statements. Indeed, one can rather easily construct counterexamples about taking (1.4) or (1.5) as near identities [CT, FADJM], and the numerical evidence was initially restricted to dimensions 1 and 2, either Anderson-type or periodic potentials, and reasonably small domains, especially in dimension 2. The latter point, in particular, could raise doubts on the applicability of these approximations in the limit of infinite domain.

The present paper is the first mathematical treatment of a rigorous connection between the landscape function and the eigenvalues of $L$ in the entire range of $\lambda$. We show that a counting function of the minima of $1/u$ yields sharp deterministic estimates from above and below on the integrated density of states, without restrictions on the underlying potential.

Passing to the statements of the results, recall that $\Omega$ is a cube in $\mathbb{R}^d$ of sidelength $R_0 \in \mathbb{N}$. For any $r > 0$ such that $R_0$ is an integer multiple of $r$, we denote by $\{Q\}_r$ a disjoint collection of cubes of sidelength $r$, such that every $Q$ is contained in $\Omega$ and $\bigcup_{Q \in \{Q\}_r} Q = \bar{\Omega}$. Our cubes are always open unless stated otherwise. We shall work with functions satisfying periodic boundary conditions on $\partial \Omega$ and, slightly abusing the notation, will often identify $\Omega$ with the torus $(\mathbb{R}/R_0 \mathbb{Z})^d$. As in the beginning of the introduction, $V$ is a bounded nonegative function on $\Omega$, $L = -\Delta + V$ is the Schrödinger operator on $\Omega$, which we take with the periodic boundary conditions,
and the integrated density of states is defined by (1.1). Going further, let \( u \) be the solution to \( Lu = 1 \) on \( \Omega \), also with periodic boundary conditions. Then it is known (and easy to prove) that \( u \) is positive and bounded, and we define

\[
(1.6) \quad N_u(\mu) := \frac{1}{|\Omega|} \times \left\{ \text{the number of cubes } Q \in \{Q\}_{\kappa \mu^{-1/2}} \text{ such that } \min_{Q} \frac{1}{u} \leq \mu \right\},
\]

where by convention \( 1 \leq \kappa < 2 \) (depending on \( \mu \)) is the smallest number such that \( R_0 \) is an integer multiple of \( \kappa \mu^{-1/2} \).

**Theorem 1.7** (The Landscape law). Retain the definitions above. There exist constants \( C_i, i = 1, \ldots, 4 \), depending on the dimension only, such that

\[
(1.8) \quad C_1 \alpha^d N_u(C_2 \alpha^{d+2} \mu) - C_3 N_u(C_2 \alpha^{d+4} \mu) \leq N(\mu) \leq N_u(C_4 \mu)
\]

for every \( \alpha < 2^{-4} \) and every \( \mu > 0 \).

The strength of Theorem 1.7 lies in its generality compared to all previously available results:

- Theorem 1.7 is not asymptotic, the estimate (1.8) is valid throughout the spectrum, with constants independent of \( \mu \).
- The constants in (1.8) do not depend on smoothness or oscillations of \( V \), nor on the possible probability law beyond its construction (or lack of thereof), nor, in fact, on the \( L^\infty \) norm of \( V \) or the size of the domain \( R_0 \). If one allows the dependence on \( \|V\|_{L^\infty(\Omega)} \), the situation for large \( \mu \) is of course rather trivial (both the density of states and \( N_u(\mu) \) roughly behave as those of the Laplacian), and similarly the scales bigger than \( R_0 \) would be easy to handle. We emphasize the lack of dependence on any of these parameters, which makes it possible to apply the theorem to the limit of an infinite potential or an infinite domain.

Looking at (1.8), one obviously faces the question of the polynomial correction in the estimate from below. And indeed, in applications (1.8) often transforms into the even stronger estimate

\[
N_u(C_2' \mu) \leq N(\mu) \leq N_u(C_4 \mu)
\]

by taking \( \alpha \) small. There are (at least) two mechanisms to achieve this, which are fortunately roughly complementary. The first one is to prove a doubling condition for the landscape \( u \).

**Theorem 1.9** (The doubling case). Retain the definitions above. If, in addition, \( u^2 \) is a doubling weight at relatively small scales, specifically, if there is a constant \( C_D \geq 1 \) such that

\[
(1.10) \quad \int_{Q_{2s}} u^2 \, dx \leq C_D \left( \int_{Q_s} u^2 \, dx + s^{d+4} \right)
\]
for every cube $Q$, of sidelength $s > 0$ then
\begin{equation}
N_u(C_2^\prime \mu) \leq N(\mu) \leq N_u(C_4 \mu) \quad \text{for every } \mu > 0,
\end{equation}
where $C_4$ is as in Theorem 1.7 and $C_2^\prime$ depends only on $C_D$ and the dimension.

In the doubling condition and everywhere below, we interpret $u$ as a function on the torus, that is, if the cubes intersect the boundary, it is understood that one uses the periodic extension of $u$.

There is a certain dichotomy between the range of applicability of Theorem 1.9 and its complement, in particular, disordered systems. Notice that (1.8) transforms into (1.11) if $N_u(\mu)$ decays sufficiently fast as $\mu$ tends to 0. This would not be the case, e.g., in the realm of periodic potentials, when one expects that both the integrated density of states and $N_u(\mu)$ behave as $\mu^{d/2}$. Fortunately, in this case $u^2$ is a doubling weight, (1.10) is satisfied, and hence we can directly apply Theorem 1.9.

A similar situation occurs when $V$ is sufficiently well-behaved. For instance, for $d \geq 3$, if $V$ satisfies the Kato condition
\begin{equation}
\sup_{z \in \mathbb{R}^d, r > 0} \int_{B_r(z) \cap \Omega} \frac{V(x)}{|x - z|^{d-2}} \, dx =: K < \infty,
\end{equation}
then (1.10) is verified and hence, the integrated density of states satisfies (1.11) directly. This can be seen as a combination of results from Theorem 1.3 in [Ku], which guarantee that for non-negative supersolutions to $(-\Delta + V)u \geq 0$ there exists $\delta > 0$ such that $u^\delta$ is doubling, and classical Moser inequalities for subsolutions to $-\Delta u \leq 1$, which allow one to bound $\sup_{Q_s} u$ by $(\int_{Q_s} u^2 \, dx)^{1/2} + r^2$ (cf. [HL], Theorem 4.14). We observe that this includes, on finite domains, even singular potentials weaker than $1/|x|^2$, but as usual, one has to pay attention to emerging constants: if (1.12) is used, the resulting constant in (1.11) may depend on $K$, which might or might not be suitable for the problem at hand. In fact, if $V$ is regular itself, (1.10) could be easier to check directly, without involving (1.12), but for now let us move to the case when (1.10) can fail.

could display pure point spectrum and exponentially decaying eigenfunctions. A certain pre-runner of Anderson localization (in fact, a simpler phenomenon of rare big regions) manifests itself through the so-called Lifschitz or Urbach tails: as $\mu \to 0$, $N(\mu)$ behaves roughly as $e^{-c\mu^{-d/2}}$ contrary to the more usual behavior $\mu^{d/2}$ observed in non-disordered systems (compare to the Weyl law above). We underline that this, once again, is an asymptotic result, now at the edge $\mu \to 0$, with a limited understanding of errors and the range where the asymptotic is precise.

A typical example of potential that destroys (1.10) is any of the Anderson-type potentials. The latter is a subclass of disordered potentials where $V$ is, for instance, a linear combination of bumps with random amplitudes taking values between 0 and 1 according to some probability law. It is a setting of the Anderson localization – a famous phenomenon when such a system, in the limit of an infinite domain,
could display pure point spectrum and exponentially decaying eigenfunctions. We shall see that in this case, although (1.10) fails, fortunately \(N_u(\mu)\) has exponential growth as \(\mu \to 0\), and hence (1.8) implies (1.11) because the exponential behavior suppresses polynomial corrections. In the terminology of [PF], such is the situation near fluctuation boundaries generally exhibited by Schrödinger operators with random (disordered) potentials. Hence, any fluctuating boundary would yield (1.11). Here we just isolate one result.

**Theorem 1.13.** Retain the definitions of \(\Omega\) and \(L\) from Section 1. Let \(\varphi \in C_0^\infty(B_{1/10}(0))\) be a nontrivial bump function supported in the ball centered at 0 of radius \(1/10\), with \(0 \leq \varphi \leq 1\), and set

\[
V = V_\omega(x) = \sum_{j \in \mathbb{Z}^d} \omega_j \varphi(x - j) \quad \text{for } x \in \Omega,
\]

where the \(\omega_j\) are i.i.d. variables taking values in \([0, 1]\), whose probability distribution

\[
F(\delta) = \mathbb{P}(\omega \leq \delta), \quad 0 \leq \delta \leq 1,
\]

is not trivial, i.e., not concentrated at one point, and such that 0 is the infimum of its support. Denote by \(N_u^E(\mu) = \mathbb{E} N_u(\mu)\) the expectation of the counting function of minima of \(1/u\), as defined in (1.6) and by \(N^E(\mu) = \mathbb{E} N(\mu)\) the expectation of the density of states, as defined in (1.1).

Then there exist constants \(C_5, C_6 > 0\) depending on the dimension and the expectation of the random variables \(\omega_j\) added an \(s\) and the name only, and a constant \(C_4 > 0\), depending on the dimension only, such that

\[
(1.14) \quad C_5 N_u^E(C_6 \mu) \leq N^E(\mu) \leq N_u^E(C_4 \mu),
\]

for every \(\mu > 0\).

Since 0 is the infimum of the support of \(F\), we have \(F(\delta) > 0\) for \(\delta > 0\); also, the measure is not a Dirac mass at the origin, so \(\lim_{\delta \to 0} F(\delta) < 1\). This implies that the common expectation \(\mathbb{E}(\omega)\) of the \(\omega_j\) lies in \((0, 1)\), and we claim that \(d\) and \(\mathbb{E}(\omega)\) alone control our constants. We will see in Theorems 3.1 and 3.5 that both numbers \(N^E(\mu)\) and \(N_u^E(\mu)\) are related to the behavior of the distribution function \(F(\delta)\), and in particular its asymptotics when \(\delta\) tends to 0, which may be complicated; here we say that the constants in these relations depend only on \(d\) and \(\mathbb{E}(\omega)\).

We underline — yet again — that Theorem 1.13 is not an asymptotic result, and multiple numerical experiments [ADFJM2] show the strength of this estimate in the intermediate regime where \(\mu\) is neither large nor small, as well as its applicability to the potentials where \(V\) is disordered but unbounded and thus, no other results for large \(\mu\) are readily available. Moreover, even in the asymptotic regimes, (1.14) offers more precision than the traditional Lifschitz tail estimates, in particular, encompassing faithfully the differences between individual choices of the disordered...
potentials; this will be discussed more thoroughly in Section 3; also see [DM+] for a detailed numerical study of the Landscape Law and its comparison to the available results in the presence of disorder. In conclusion, we would like to zoom back out from the specific applications and to reiterate that the Main Theorem should be viewed as a form of the Uncertainty Principle whose generality is not inhibited by properties of the potential or range of the energies, a “black box” which gives good bounds on the density of states irrespectively of the physical nature of the initial system.

Acknowledgements. We thank Douglas Arnold and David Jerison for uncountable inspiring conversations on the subject and the joint work [ADFJM3, ADFJM2] which lies at the foundation of the results in this paper. The third author would also like to thank T. Spencer and L. Pastur for many stimulating discussions, and W. König, Z. Shen, and W. Kirsch, for sharing some references and the historical perspective.

2. Main estimates: doubling and non-doubling scenario

Step I: the upper bound. We start with the upper bound on $N(\mu)$. The estimate $N(\mu) \leq N$ is valid if we can find $H_N$, a codimension $N$ subspace of $H$ (where $H$ is the space of periodic functions in $W^{1,2}(\Omega)$), such that

$$\langle Lv, v \rangle = \int_{\Omega} |\nabla v|^2 + V v^2 \, dx \int_{\Omega} v^2 \, dx > \mu$$

for all $v \in H_N$.

To this end, denote

$$\mathcal{F} := \left\{ Q \in \{Q\}_{\kappa \mu^{-1/2}} \text{ such that } \min_{Q} \frac{1}{u} \leq C_4 \mu \right\},$$

with $C_4$ to be defined below, and $1 \leq \kappa < 2$ (depending on $\mu$) is the smallest number such that $R_0$ is an integer multiple of $\kappa \mu^{-1/2}$. Then let $H_N$ be the space of $v \in H$ such that $\int_{Q} v \, dx = 0$ for every $Q \in \mathcal{F}$. Since the cubes $Q \in \mathcal{F}$ are disjoint, it is evident that $H_N$ has co-dimension $N = \text{Card} \mathcal{F}$, simply taking the bumps on $Q$’s as an orthogonal complement of $H_N$.

We recall from [ADFJM1], Lemma 4.1, that

$$\int_{\Omega} |\nabla v|^2 + V v^2 \, dx \geq \int_{\Omega} \frac{1}{u} v^2 \, dx$$

for all $v \in H$. 
and hence,

$$2 \int_{\Omega} |\nabla v|^2 + V v^2 \, dx \geq \int_{\Omega} |\nabla v|^2 + \frac{1}{u} v^2 \, dx \quad \text{for all } v \in H,$$

Thus, it is enough to prove that

$$\int_{\Omega} |\nabla v|^2 + \frac{1}{u} v^2 \, dx > 2\mu \int_{\Omega} v^2 \, dx \quad \text{for all } v \in H_N \setminus \{0\}.$$

On the part of $\Omega$ corresponding to any $Q \in \{Q_k \}_{k=0}^{k=1/2}$ such that $Q \notin F$ the bound (2.1) is valid provided that $C_4 > 2$ because $\min_{\Omega} \frac{1}{u} \geq C_4\mu$ on such cubes. For $Q \in F$, we use the Poincaré inequality to write

$$\int_{Q} |\nabla v|^2 \, dx \geq C_P C_4 \mu \int_{Q} |v - v_Q|^2 \, dx = C_P C_4 \mu \int_{Q} v^2 \, dx,$$

where $C_4\mu$ comes from the size of $Q$ and we used the fact that $v_Q = \int_{Q} v \, dx = 0$ by the definition of $H_N$. Here $C_P$ is the Poincaré constant and depends on the dimension only. Choosing $C_4$ so large that $C_P C_4 > 2$, we arrive at the desired estimate.

**Step II: the lower bound in the doubling case.** In this direction, in order to prove that $M \leq N(\mu)$, we need to find $H_M$, a subspace of $H$ of dimension $M$, such that

$$\langle Lv, v \rangle := \frac{\int_{\Omega} |\nabla v|^2 + V v^2 \, dx}{\int_{\Omega} v^2 \, dx} \leq \mu \quad \text{for all } v \in H_M.$$  

To this end, let

$$F' := \left\{ Q \in \{Q_k \}_{k=0}^{k=1/2} \text{ such that } \min_{\Omega} \frac{1}{u} \leq C_2\mu \right\},$$

where $C_2$ will be chosen below. Let $H_M$ be the linear span of the functions $u \chi_Q$. $Q \in F'$, picked such that $\chi_Q \in C_0^\infty(Q), \chi_Q = 1$ on $Q/2$, $0 \leq \chi \leq 1$ on $Q$, and $|\nabla \chi_Q| \leq 4l(Q)^{-1}$.

Since $-\Delta u \leq 1$, the Moser-Harnack inequality ([HL], Theorem 4.14) yields

$$\sup_{Q} u \leq C_H \left( \frac{1}{|Q|} \int_{Q} u^2 \right)^{1/2} + C_H l(Q)^2,$$

where $C_H$ depends on the dimension only. In particular, using also the doubling condition three times,

$$\sup_{Q} u \leq C_H C_D^{3/2} \sup_{Q/4} u + C' l(Q)^2,$$

where $C' = C'(C_D, C_H)$ is a constant depending on $C_D, C_H$, and the dimension only.

We use (1.3), the definition of $\chi_Q$, (2.4) for $Q/4$, and (2.5)
\( \langle L(u|_{\partial Q}), u|_{\partial Q} \rangle \frac{\|u|_{\partial Q}\|^2_{L^2(\Omega)}}{\|\nabla u\|^2_{L^2(\Omega)}} \leq \frac{16 l(C)^2 \int_Q u^2 \, dx + \int_Q u \, dx}{\int_{\partial Q} u^2 \, dx} \leq 4^{-d} \left( \frac{1}{C_\kappa} \sup_{Q/4} u^2 + \frac{1}{16} l(C)^2 \right)^2 \leq 4^{-d} l(C)^2 \sup_{Q} u^2 + 4^d \sup_{Q} u \left( \frac{1}{C_\kappa^2 C_D^3} \sup_{Q} u - \left( \frac{1}{16} + \frac{C'}{C_\kappa^2 C_D^3} \right) l(C)^2 \right)^2. \)

We temporarily choose \( \kappa \) small enough in terms of \( C_D \) and \( C_H \) so that
\[
\frac{1}{2C_D^2 C_H^{3/2}} \sup_{Q} u \geq \left( \frac{1}{16} + \frac{C'}{C_\kappa^2 C_D^3} \right) l(C)^2,
\]
and then, for some constants \( C_{d,5}, C'_{d,5}, C_{d,5} \) depending on the dimension, \( C_D \), and \( C_H \) we have
\[
\frac{\langle L(u|_{\partial Q}), u|_{\partial Q} \rangle}{\|u|_{\partial Q}\|^2_{L^2(\Omega)}} \leq C_{d,5} l(C)^2 + C_{d,5}' \frac{1}{\sup_{Q} u} \leq C_{d,5} C_2 \mu,
\]
where the last inequality comes from the definition (2.3) of \( \mathcal{F}' \). Having fixed \( \kappa \) as above, we now choose \( C_2 \) such that \( C_{d,5} C_2 = 1 \) and arrive at the desired estimate. To be precise, we only showed the desired inequality on the elements of the basis of \( H_M \) but since the cubes \( Q \) are disjoint, we immediately get it for any element of \( H_M \) as well. The only difference with what we want is that the estimate we achieved is in terms of the cardinality of a set \( \mathcal{F}' \) defined with an artificially small \( \kappa \).

However, if we increase the \( \kappa \) to our usual fork \( 1 \leq \kappa < 2 \), the cardinality of the resulting set \( \mathcal{F} \) becomes even smaller, and our basis \( H_M \) has less elements than expected, as desired.

**Step III: the lower bound in the non-doubling case.** Our goal, once again, is to establish (2.2) for some subspace \( H_M \) of dimension \( M \). This time, we pick any \( \alpha \in (0, 1/16] \) and consider cubes of sidelength \( R = \kappa (C^* \alpha^{d+4} \mu)^{-1/2} \). For \( Q \in \{Q\}_R \), denote by \( \tilde{Q} = Q \), the cube concentric with \( Q \) but with the smaller sidelength \( r = \alpha R = \kappa (C^* \alpha^{d+2} \mu)^{-1/2} \). Now take
\[
\mathcal{F}' := \left\{ Q \in \{Q\}_R \text{ such that } \min_{Q} \frac{1}{u} \leq C^* \alpha^{d+2} \mu \text{ and } \min_{Q} \frac{1}{u} \geq C^* \alpha^{d+4} \mu \right\},
\]
and let \( H_M \) be the linear span of the functions \( u|_{\tilde{Q}}, Q \in \mathcal{F}' \), where we pick \( \chi_{Q} \in C_0^\infty(Q), 0 \leq \chi_{Q} \leq 1 \), such that \( \chi_{Q} = 1 \) on \( 2\tilde{Q} \) and \( |\nabla \chi_{Q}| \leq CR^{-1} \). As before, we want to estimate
\[
\frac{\langle L(u|_{\partial Q}), u|_{\partial Q} \rangle}{\|u|_{\partial Q}\|^2_{L^2(\Omega)}} = \frac{\int u^2 |\nabla u|^2 + u |\chi_{Q}|^2 \, dx}{\int (u|_{\partial Q})^2 \, dx}
\]
(by (1.3)). By definition of \( \mathcal{F}' \), \( u \leq (C^* \alpha^{d+4} \mu)^{-1} \) on \( Q \), so the numerator is at most \( C^2 R^{-2} \int_Q u^2 + \int_Q u \leq (C^* \alpha^{d+4} \mu)^{-1} |Q|(C^2 \kappa^{-2} + 1) \). For the denominator \( D \), we first apply the Moser-Harnack inequality (2.4) to \( \tilde{Q} \), then the definition of \( \mathcal{F}' \), to get that
\[ D \geq \int_{2Q} u^2 \geq |\hat{Q}| \left[ C_H^{-1} \sup_{\hat{Q}} u - \ell(\hat{Q})^2 \right]^2 = \alpha^d |Q| \left[ C_H^{-1} \sup_{Q} u - \alpha^2 R^2 \right]^2 \]
\[ \geq \alpha^d |Q| \left[ C_H^{-1}(C^* \alpha^{d+2} \mu)^{-1} - \kappa^2 \alpha^2 (C^* \alpha^{d+4} \mu)^{-1} \right]^2 = \alpha^d |Q|(C^* \alpha^{d+2} \mu)^{-2} [C_H^{-1} - \kappa^2]^2. \]

We chose \( \kappa^2 \leq \frac{1}{2} \mu \); then the first term dominates the second one and the expression in (2.9) is bounded by

\[ (2.10) \quad \frac{C_{d,6}(C^* \alpha^{d+4} \mu)^{-1}}{C_{d,7}(C^* \alpha^{d+2} \mu)^{-2}} \leq C_{d,8} C^* \mu = \mu, \]

provided that we choose \( C^* = C_{d,8}^{-1} \). Then, using the orthogonality of the \( \chi_Q \), we get

\[ N(\mu) \geq \text{Card} \left\{ Q \in \{Q\}_R \mid \min_{\hat{Q}} \frac{1}{u} \leq C^* \alpha^{d+2} \mu \quad \text{and} \quad \min_{\hat{Q}} \frac{1}{\hat{Q}} \geq C^* \alpha^{d+4} \mu \right\} \geq N_1 - N_2, \]

where

\[ N_1 = \text{Card} \left\{ Q \in \{Q\}_R \mid \min_{\hat{Q}} \frac{1}{u} \leq C^* \alpha^{d+2} \mu \right\}, \]
\[ N_2 = \text{Card} \left\{ Q \in \{Q\}_R \mid \min_{\hat{Q}} \frac{1}{\hat{Q}} \leq C^* \alpha^{d+4} \mu \right\}. \]

Notice that the cubes \( \hat{Q} = Q \), in this argument are smaller and do not cover \( \Omega \), so \( N_1 \) is probably not as large as \( N'_1 = \text{Card} \left\{ R \in \{Q\}_R \mid \min_{\hat{R}} \frac{1}{u} \leq C^* \alpha^{d+2} \mu \right\} \). However, keeping in mind that we can treat \( \Omega \) as a torus, we can do the estimate above for a collection of translations of our cubes \( Q \) by a collection of at most \( C \alpha^{-d} \) small vectors \( e_j \), \( j \in J \), so that when we take the cubes \( \tilde{Q} = Q_R \) as above, the smaller cubes \( \hat{Q} + e_j, \hat{Q} \in \{Q\}_R \) and \( J \), cover \( \Omega \). This implies that the sum of the corresponding numbers \( N_1 \) is at least

\[ C^{-1} N_u(C^* \alpha^{d+2} \mu), \]

where \( N_u \) is defined in (1.6) and \( C \) accounts for a slight difference between \( r \) and the official radius \( \kappa(C^* \alpha^{d+2} \mu)^{-1/2} \) associated to \( C^* \alpha^{d+2} \mu \). Let us pick a nearly optimal translation \( e_j \), so that \( N_1 \geq C^{-1} \alpha^d N_u(C^* \alpha^{d+2} \mu) \).

Similarly, \( N_2 \leq C N_u(C^* \alpha^{d+4} \mu) \), and thus by the estimate above

\[ N(\mu) \geq C^{-1} \alpha^d N_u(C^* \alpha^{d+2} \mu) - C N_u(C^* \alpha^{d+4} \mu). \]

This is precisely the bound (1.8). □

It is important to point out that Theorem 1.7 does not rely on the condition \( V \in L^p(\Omega) \) and there is no dependence in constants on \( \|V\|_{L^p(\Omega)} \) or on the size of the domain \( R_0 \). This is one of the main features of our estimates. If instead one allows our estimates to depend on \( \|V\|_{L^p(\Omega)} \), the situation for large \( \mu \) is of course rather trivial, as both the density of states and \( N_u(\mu) \) roughly behave as those for
the Laplacian. In particular, there exist constants $C_5, C_2, C_4$ depending on the dimension only, such that (1.11) is valid for all $\mu > C_5 \|V\|_{L^{\infty}(\Omega)}$. We will use an enhanced version of this statement in the next section.

3. Anderson-type potential

We start this section with estimates on the expectation of the counting function $N_u(\mu)$ associated to the landscape as in (1.6).

**Theorem 3.1.** Let $\Omega$ and $L = -\Delta + V$ be as in Theorem 1.13. In particular, let $\varphi \in C_0^\infty(B_{1/10}(0))$ be such that $0 \leq \varphi \leq 1$, and set

$$V(x) = \sum_{j \in \mathbb{Z}^d} \omega_j \varphi(x - j), \quad x \in \Omega,$$

where the $\omega_j$ are i.i.d. variables taking values $\omega_j \in [0, 1]$ with a probability distribution

$$F(\delta) = \mathbb{P}\{\omega \leq \delta\}, \quad 0 \leq \delta \leq 1,$$

which is not concentrated at one point, and such that $0$ is the infimum of its support. Denote by $N_u^E(\mu) = \mathbb{E} N_u(\mu)$ the expectation of the counting function of the minima of $1/u$, as defined in (1.6). Then there exist constants $\mu^*, c_P, \gamma_1, \gamma_2$, depending on the dimension and the common expectation of the random variables $\omega_j$ only, and constants $m$, $c_P$, $\gamma_3$, $\gamma_4$, depending on the dimension only, such that

$$\gamma_3 \mu^{d/2} F(c_P \mu)^{\gamma_4 - d/2} \leq N_u^E(\mu) \leq \gamma_1 \mu^{d/2} F(c_P \mu)^{\gamma_3 - d/2},$$

whenever $\mu < \mu^*$ and $R_0 > (\mu m)^{-1/2}$.

Let us put this Theorem into the context of known results for the Lifschitz tails. On the way to our ultimate goals, we will show the following by-product of Theorem 1.13.

**Theorem 3.5.** Retain the notation and assumptions of Theorem 1.13. Then there exist constants $\mu^*, m, c_P, \gamma_1, \gamma_2$, depending on the dimension and the expectation of the random variable only, and constants $\tilde{c}_P, \gamma_3, \gamma_4$ depending on the dimension only, such that

$$\gamma_3 \mu^{d/2} F(c_P \mu)^{\gamma_4 - d/2} \leq N_u^E(\mu) \leq \gamma_1 \mu^{d/2} F(c_P \mu)^{\gamma_3 - d/2},$$

whenever $\mu < \mu^*$ and $R_0 > (\mu m)^{-1/2}$.

This result, and in particular the traditionally sought-after estimate (3.7), is in itself stronger than formally known asymptotics of the density of states, particularly for the continuous model, although it is fair to say that (3.7) would be expected by specialists in the subject and perhaps could even be addressed by other methods.
than those in the present paper. Let us explain the situation in the currently available literature.

The literature devoted to Lifschitz tails is extensive, particularly if one includes Poisson and other models, and we do not thrive here to give a comprehensive list of references or methodology – see, e.g., [KM, Ko, PF] for surveys of related results. Here we just provide some pointers which will highlight the novelties of (3.7) (silently passing to the limit of infinite domain and removing the superscript $E$).

The early literature, by now considered classical, and many modern textbooks treat the case when $F(\delta) \geq C\delta^\beta$ for some $C, \beta > 0$, and provide the asymptotics

$$\lim_{\mu \to 0} \frac{\log |\log N(\mu)|}{\log \mu} = -\frac{d}{2},$$

(3.8)

see, for instance, [K, S]. The quantity

$$L := \lim_{\mu \to 0} \frac{\log |\log N(\mu)|}{-\log \mu}$$

is generally known as a Lifschitz exponent, and, in addition to the results above, it is proved in [PF] that

$$\lim_{\mu \to 0} \frac{-\log F(\mu)}{-\log \mu} = a > 0 \implies L = d/2 + a.$$

Theorems 1.13 and 3.5 ascertain that for any non-trivial $F$ such that $F(\delta) > \delta$ for $\delta > 0$, we can recover the Lifschitz exponent from the behavior of the landscape counting function

$$L \equiv L_u, \quad \text{where} \quad L_u := \lim_{\mu \to 0} \frac{\log |\log N_u(\mu)|}{-\log \mu}$$

(assuming for simplicity that the limit exists) and in particular,

$$L = \frac{d}{2} + \lim_{\mu \to 0} \frac{-\log F(\mu)}{-\log \mu},$$

(3.10)

without any a priori restrictions on $F$. This formally recovers and generalizes the results mentioned above. In the context of our methods, however, such statements lose much of the precision exhibited in (1.14), (3.6), (3.7).

Indeed, the problem of (3.8) is not only, or not so much, the restricted class of the potentials to which it applies, but rather the notorious imprecision of double-logarithmic asymptotics. The underlying method of proof in [K, S] factually gives

$$\gamma_3 \mu^{d/2} F(\mu) \leq N^E(\mu) \leq e^{-\gamma^' \mu^{d/2}}.$$

In general, the upper bound is larger than the lower bound and does not give sufficient precision to improve the double logarithm – see the discussion and the related conjectures in [K].
This is a well-known problem. The subtle difference between refined asymptotics roughly speaking asserting that \(N(\mu) \sim e^{-c\mu^{-d/2}}\) and those with the logarithmic correction \(N(\mu) \sim e^{c\mu^{-d/2} \log \mu}\) has not been overlooked in the literature. However, the refined estimates turned out to be much more challenging. At this point they are only available in \(\mathbb{Z}^d\) rather than \(\mathbb{R}^d\) and under various additional constraints on the probability distribution – see [Ko] and [M]\(^2\). The proofs pass through the parabolic Anderson model – an approach not yet developed, to the best of our knowledge, in the context of the alloy Anderson model on \(\mathbb{R}^d\) considered in the present paper. And, even in \(\mathbb{Z}^d\), the situation has been far from well-understood. Both the conditions on the potential and the results in [Ko] and [M] are quite technical, so we will not provide the detailed statements. Let us just mention that they appeal to various cases according to the behavior of the scale function

\[ S(\lambda, t) = (\lambda t)^{-1} G(\lambda t) - t^{-1} G(t), \quad \text{where} \quad G(t) = \log \mathbb{E}(\exp(-tV(0))), \]

(whether \(S \sim C(\lambda^d - 1)t^\rho\) with \(C, \rho\) positive or negative, or \(S \sim C \log \lambda\), or \(S \sim -C(\lambda t)^{-1} \log t\) and draw the asymptotics in terms of \(I(\mu) = \sup_{\gamma > 0}(\mu t - G(t))\)). Such is the presentation in [M], and [Ko] gives somewhat different statements, also with a dependence on the features of a certain implicitly defined scale function. The strength of these results compared to Theorem 3.5 is that, at least in some cases, they provide actual asymptotics rather than the estimates from above and below and feature a number of cases that we did not explicitly consider, such as unbounded potentials. The weakness is that their coverage does not encompass all potentials, even among the bounded ones, and at this point is completely restricted to \(\mathbb{Z}^d\).

By contrast, Theorem 3.5 provides a simple and universal law, covering all bounded potentials at once, clearly identifying the source of the logarithmic correction, the “Pastur tails” (3.10), the exact transition from the classical to quantum regime. Below are just a few examples of applications of (3.7):

1. \(V\) is a Bernoulli potential: \(\omega\) takes values 0 or 1 with probability 1/2. Then
   \[
   \gamma_3 \mu^{d/2} e^{-\gamma_4 \mu^{-d/2}} \leq N_E(\mu) \leq \gamma_1 \mu^{d/2} e^{-\gamma_2 \mu^{-d/2}}.
   \]

2. \(V\) is given by a uniform distribution on \([0, 1]\) or any other \(F\) such that \(F(\delta)\) is bounded from above and below by some positive power of \(\delta\). This leads to logarithmic correctors predicted in the physics literature [LN, PS]
   \[
   \gamma_3 \mu^{d/2} e^{\gamma_4 \mu^{-d/2} \log \mu} \leq N_E(\mu) \leq \gamma_1 \mu^{d/2} e^{\gamma_2 \mu^{-d/2} \log \mu}.
   \]

3. \(V\) is given by the probability distribution with \(F(\delta) \sim e^{-C\delta^a}\), \(a > 0\). Then
   \[
   \gamma_3 \mu^{d/2} e^{\gamma_4 \mu^{-d/2-a}} \leq N_E(\mu) \leq \gamma_1 \mu^{d/2} e^{\gamma_2 \mu^{-d/2-a}}.
   \]

\(^2\text{We are using here the review of these results from [KM]. Unfortunately, the dissertation [M] has never been published and so we cannot attest to the validity of the proofs or to exact statements beyond what has been quoted [KM].}\)
This is an example of (3.10).

With this, we return to the proof of Theorem 3.1. Our initial lemma is purely deterministic.

**Lemma 3.11.** Let $\Omega$ and $L$ be as in Section 1, with $V$ defined as follows. Let $\varphi \in C^\infty_0(B_{1/10}(0))$ be such that $0 \leq \varphi \leq 1$, and set
\[
V = V_\omega(x) = \sum_{j \in \mathbb{Z}^d} \omega_j \varphi(x - j), \quad x \in \Omega,
\]
where the sequence $\omega = \{\omega_j\}_{j \in \mathbb{Z}^d}$ takes values in $[0, 1]$. For $r \in [\sqrt{d}, R_0]$, where we recall that $R_0$ is the scale of $\Omega$, let us denote by $Q_r = Q_r^\omega$ the maximal cube consisting of unit cubes centered on $\mathbb{Z}^d$ (and with edges parallel to the axes) which is contained in $B_{r/2}(0)$. Since $r \geq \sqrt{d}$, $Q_r$ contains at least one unit cube.

Assume that $r \in [3\sqrt{d}, R_0]$ is such that
\[
\text{Card}\{j \in Q_r \cap \mathbb{Z}^d : \omega_j \geq c_P r^{-2}\} \geq \lambda |Q_r|,
\]
for some $c_P, \lambda > 0$.

If $c_P$ is large enough, depending on $\lambda$ and the dimension only, then there exist $\varepsilon = \varepsilon(\lambda, d) > 0$ (small) and $M = M(\varepsilon, \lambda, d) > 0$ (large) such that if $\xi_0 \in B_{r/3}(0)$ is such that
\[
u(\xi_0) \geq Mr^2
\]
then
\[
u(\xi) \geq (1 + \varepsilon) \nu(\xi_0) \quad \text{for some point} \quad \xi \in B_{\sqrt{1 + \varepsilon}(\xi_0)}.
\]

Again this is a deterministic statement, for which we do not care where the $\omega_j$ are coming from and probabilistic considerations are irrelevant. That is, at this point $V$ could be any realization, even extremely unlikely, of the construction described in Theorem 3.1, even if we intend to show later that our assumption (3.12) is quite probable in some circumstances.

Here we gave a statement for a point $\xi_0 \in B_{r/3}(0)$ so that we can take $Q_r$ centered at the origin, but a similar statement for any $\xi_0 \in \Omega$ would be easy to obtain, because we could use the translation invariance of our problem by $\mathbb{Z}^d$ to apply the result to $\xi_0 - \overline{\xi}_0$, where $\overline{\xi}_0 \in \mathbb{Z}^d$ is such that $\overline{\xi}_0 - \overline{\xi}_0 \in B_{r/3}(0)$; we assumed $r \geq 3\sqrt{d}$ only to guarantee that we can find $\overline{\xi}_0$. We will use this comment about other centers $\xi_0$ later in the proof.

**Proof.** Because of the periodic nature of $\Omega$ and $L$, we may assume that $\Omega$ is centered at the origin; we do not assume that $\xi_0 = 0$ because $\mathbb{Z}^d$ plays a special role in the definition of $V$.

**Step I.** Let $\xi_0 \in \Omega$ be given, set $B_{\rho} = B_{\rho}(\xi_0)$ (for computations on $u$, we like to think that $\xi_0$ is the origin) and denote by $m(\rho) = m(\xi_0, \rho)$ the average of $u$ on the
sphere centered at $\xi_0$ with radius $\rho$. That is, when $d \geq 2$ we set

$$m(\rho) = \int_{\partial B_\rho} u \, d\sigma, \quad \rho > 0,$$

where $d\sigma$ is the $(d - 1)$ dimensional surface measure on $\partial B_\rho$, and when $d = 1$

$$m(\rho) = \frac{u(\xi_0 + \rho) + u(\xi_0 - \rho)}{2}, \quad \rho > 0.$$

For brevity, we set $m(0) = u(\xi_0)$; this makes sense because $u$ is continuous on $\Omega$.

We claim that

$$m(\rho) \leq m(r) + r^2 - \rho^2 \quad \text{for} \quad 0 \leq \rho < r < \text{dist} (\xi_0, \partial \Omega),$$

and in particular,

$$m(r) \geq m(0) - r^2.$$

This can be seen, for instance, by comparison with harmonic functions. Let $v$ be a solution to $-\Delta v = 0$ in $B_r$ that coincides with $u$ on $\partial B_r$ and set $w(y) := v(y) + r^2 - |y - \xi_0|^2$ for $y \in B_r$. Then $-\Delta w = 2d \geq 1 \geq -\Delta u$ in $B_r$ (because $Lu = -\Delta u + Vu = 1$ and $V \geq 0$) and $w = v = u$ on $\partial B_r$. Hence, $w \geq u$ by the maximum principle, so that

$$m(\rho) = \int_{\partial B_\rho} u \, d\sigma \leq \int_{\partial B_\rho} w \, d\sigma = \int_{\partial B_\rho} v \, d\sigma + r^2 - \rho^2 = m(r) + r^2 - \rho^2,$$

where we used the mean value property for harmonic functions in the last equality. The estimates (3.15)–(3.16) follow.

Furthermore, when $d \geq 2$, the Poisson formula for a harmonic function $v$ in $B_r$ yields

$$v(y) = \frac{r^2 - |y - \xi_0|^2}{\alpha_d r} \int_{\partial B_r} \frac{v(z)}{|z - y|^d} \, d\sigma_z,$$

where $\alpha_d$ is the volume of a unit ball in $\mathbb{R}^d$. Hence there exists a dimensional constant $c_1$ such that $v(y) \leq c_1 m(r)$ for all $y \in B_{2r/3}$. The same is of course true when $d = 1$, because harmonic functions on $\mathbb{R}$ are affine. Moreover, since

$$u(y) \leq w(y) = v(y) + r^2 - |y - \xi_0|^2,$$

we get that

$$u(y) \leq c_1 m(r) + r^2 \quad \text{for} \quad y \in B_{2r/3}.$$

Notice that $c_1$ can be taken equal to 1 when $y = x$, according to (3.16).

**Step II.** Now we want to use the size of $V$. Integrating by parts against the Green function in a ball, we get for $d \geq 3$

$$m(r) = m(0) + c_2 \int_{B_r} \Delta u(y) \left(|y - \xi_0|^{2-d} - r^{2-d}\right) \, dy$$
\[m(0) + c_2 \int_{B_r} (Vu - 1) \left( |y - \xi_0|^{2-d} - r^{2-d} \right) \, dy\]

for some dimensional constant \(c_2 > 0\) and as usual assuming \(\overline{B}_r \subset \Omega\).

Now assume that \(0 \leq r \leq R\) and \(\overline{B}_R \subset \Omega\), and subtract (3.18) for \(R\) from this; we get that

\[(3.19) \quad m(R) - m(r) = c_2 \int_{B_R \setminus B_r} (Vu - 1) \left( |y - \xi_0|^{2-d} - R^{2-d} \right) \, dy + c_2 \int_{B_r} (Vu - 1) \left( r^{2-d} - R^{2-d} \right) \, dy\]

Recall that we are interested in \(\xi_0 \in \overline{B}_{r/3}(0)\), so that since \(Q_r \subset B_{r/2}(0)\), it is contained in \(B_r = B_r(\xi_0)\). We will only keep the contribution of \(V\) on \(Q_r\) (because we want to use its simpler structure), and since

\[\int_{B_R \setminus B_r} \left( |y - \xi_0|^{2-d} - R^{2-d} \right) \, dy + \int_{B_r} \left( r^{2-d} - R^{2-d} \right) \, dy \leq CR^d (r^{2-d} - R^{2-d}) \leq C(R^2 - r^2)\]

(3.19) yields

\[(3.20) \quad m(R) - m(r) \geq -c_3 (R^2 - r^2) + c_2 (r^{2-d} - R^{2-d}) \int_{Q_r} Vu \, dy,\]

In dimension \(d = 2\) one has

\[(3.21) \quad m(r) = m(0) + c_2 \int_{B_r} (Vu - 1) \log \frac{r}{|y - \xi_0|} \, dy\]

in place of (3.18), and since

\[\int_{B_R \setminus B_r} \log \frac{r}{|y - \xi_0|} \, dy + \int_{B_r} \log \frac{R}{r} \, dy \leq C(R^2 - r^2) + C r^2 \log \frac{R}{r} \leq C(R^2 - r^2),\]

we obtain

\[(3.22) \quad m(R) - m(r) \geq -c_3 (R^2 - r^2) + c_2 \log \frac{R}{r} \int_{Q_r} Vu \, dy\]

in place of (3.20). In dimension \(d = 1\), (3.18) becomes

\[(3.23) \quad m(r) = m(0) + c_2 \int_{B_r} u''(y) (r - |y - \xi_0|) \, dy = m(0) + c_2 \int_{B_r} (Vu - 1) (r - |y - \xi_0|) \, dy\]

and hence we have

\[(3.24) \quad m(R) - m(r) \geq -c_3 (R^2 - r^2) + c_2 (R - r) \int_{Q_r} Vu \, dy\]

in place of (3.20).
Step III. Write \( Q_r = \bigcup_{j \in J} R_j \), where \( R_j \) is the cube of unit sidelength centered at \( j \in \mathbb{Z}^d \), and \( J = \mathbb{Z}^d \cap Q_r \) precisely corresponds to the cubes \( R_j \) that are contained in \( Q_r \). Then set

\[
J_V := \{ j \in J : \omega_j \geq c_P r^{-2} \}.
\]

Observe that since \( V(x) = \sum \omega_j \varphi(x - j) \), with \( \varphi \in C_0^\infty(B_{1/10}(0)) \), we have that \( \int_{R_j} V = \omega_j \int_{R_0} \varphi \), where \( R_0 \) (exceptionally) denotes the unit cube centered at 0. Thus

\[
J_V := \{ j \in J : \int_{R_j} V \geq c_P r^{-2} \},
\]

with \( c_P = c_P \int_{R_0} \varphi \).

Denote by \( m_r \) the average of \( u \) on the ball \( B_r(\xi_0) \) (notice the difference with \( m(r) \) which is an average on the sphere) and let \( u_j := \inf_{R_j} u \). Now pick some \( \eta > 0 \) (a dimensional constant to be chosen below) and let

\[
J_\eta = \{ j \in J_V : u_j < \eta m_r \}.
\]

Step IV. We start with the case when

\[
\text{Card } J_\eta \geq \frac{\lambda}{2} |Q_r|.
\]

By Harnack’s inequality at scale 1 (see, [GT], Theorem 8.18),

\[
\int_{R_j} u \, dx \leq 2d \int_{2R_j} u \, dx \leq C \left( \inf_{R_j} u + 1 \right).
\]

Since, in addition, \( u \geq 1 \) on \( \Omega \) (recall that \( 0 \leq V \leq 1 \) here, and see [ADFJM1], Proposition 3.2), we have

\[
\int_{R_j} u \, dx \leq C^*_H \inf_{R_j} u,
\]

for some constant \( C^*_H \) depending on the dimension only. Therefore,

\[
\int_{R_j} u \, dx = \int_{R_j} u \, dx \leq C^*_H \eta m_r \quad \text{for any } j \in J_\eta.
\]

Then

\[
\int_{B_r \setminus \bigcup_{j \in J_\eta} R_j} u \, dx \geq |B_r| m_r - C^*_H \eta m_r \text{ Card } J_\eta
\]

and

\[
\int_{B_r \setminus \bigcup_{j \in J_\eta} R_j} u \, dx \geq \frac{|B_r| - C^*_H \eta \text{ Card } J_\eta}{|B_r| - \text{ Card } J_\eta} m_r = \left( 1 + \frac{(1 - C^*_H \eta) \text{ Card } J_\eta}{|B_r| - \text{ Card } J_\eta} \right) m_r \geq (1 + c_3 \lambda) m_r,
\]

for \( \eta = (2C^*_H)^{-1} \) and a suitable dimensional constant \( c_3 \). We conclude that there exists a point \( \xi \in B_r \) such that
\( u(\xi) \geq (1 + c_3 \lambda) m_r \geq (1 + c_3 \lambda)(m(0) - r^2) \)
\[
\geq m(0) + c_3 \lambda m(0) - m(0) (1 + c_3 \lambda) / M
\]
where we integrated (3.16) for the second inequality and used the fact that \( m(0) = u(\xi_0) \geq M r^2 \) by (3.13) in the third one. If we fix
\[
M \geq \frac{c_4}{\lambda}
\]
then there exists a point \( \xi \in B_r \) such that
\[
u(\xi) \geq (1 + c_5 \lambda) m(0),
\]
where as usual all \( c_i \) depend on the dimension only. Hence, choosing
\[
\epsilon < c_5 \lambda,
\]
we arrive at (3.14).

**Step V.** Assume now that, on the contrary,
\[
\text{Card } J_\eta \leq \frac{\lambda}{2} |Q_r|.
\]
Let \( R = \sqrt{1 + \epsilon r}, \epsilon < 1/2 \). First assume that \( d \geq 3 \); then by (3.20),
\[
m(R) - m(r) \geq -c_3 (R^2 - r^2) + c_2 \left( r^{2-d} - R^{2-d} \right) \int_{Q_r} V u \, dy
\]
\[
\geq -c_3 (R^2 - r^2) + c_2 \left( r^{2-d} - R^{2-d} \right) \sum_{j \in J \setminus J_\eta} \int_{R_j} V u \, dy.
\]
But for such \( j \), \( \int_{R_j} V u \, dy \geq u_j \int_{R_j} V \, dy \geq \eta m_r \int_{R_j} V \geq \eta m_r c' r^{-2} \) by various definitions including (3.26) and (3.27). Thus, since \( R = \sqrt{1 + \epsilon r} \),
\[
m(R) - m(r) \geq -c_3 (R^2 - r^2) + c_2 \left( r^{2-d} - R^{2-d} \right) c' r^{-2} \eta m_r \left( \text{Card } J \setminus \text{Card } J_\eta \right)
\]
\[
\geq -c_3 \epsilon r^2 + c_6 \epsilon c' m_r \lambda.
\]
When \( d = 1, 2 \), we use (3.22) and (3.24) instead of (3.20), and get the same final estimate, namely
\[
m(R) - m(r) \geq -c_3 \epsilon r^2 + c_6 \epsilon c' m_r \lambda
\]
(possibly further adjusting \( c_3 \) and \( c_6 \) still depending on dimension only). Using (3.16) and its integrated version for \( m_r \), and then the fact that \( m(0) \geq M r^2 \) by (3.13), we obtain that
\[
m(R) \geq m(0) - r^2 - c_3 \epsilon r^2 + c_6 \epsilon c'_r \lambda \left( m(0) - r^2 \right)
\]
\[
\geq m(0) \left( 1 + c_6 \epsilon c'_r \lambda \left( 1 - \frac{1}{M} \right) - \frac{1 + c_3 \epsilon}{M} \right).
\]
Choosing $c_P$ so large that
\begin{equation}
    c_P' \geq \frac{4}{c_{\theta} \lambda}
\end{equation}
(recall Step III) and $M$ such that
\begin{equation}
    M > c_\gamma \max \left\{ 1, \frac{1}{c', \frac{1}{\lambda}} \right\}
\end{equation}
(the third part takes care of (3.29)) we ensure that the second term in the parentheses above is larger than $2\varepsilon$ and the third term smaller than $\varepsilon$, so that
\[m(R) \geq m(0)(1 + \varepsilon)\]
and hence, (3.14) holds for some $\xi \in \partial B_R$, as needed for (3.14).

**Lemma 3.34.** Let $\Omega$ and $L = -\Delta + V$ be as in Theorems 1.13 and 3.1. In particular $V$ is a random potential governed by a probability measure, as in (3.2) and (3.3). Fix $0 < \lambda < 1$. Then choose $c_P = c_P(\lambda, d)$ large enough, $\varepsilon = \varepsilon(\lambda, d) > 0$ small enough, and $M = M(\varepsilon, \lambda, d) > 0$ large enough, as in Lemma 3.11.

Recall that $\Omega = \mathbb{R}^d / \mathbb{Z}^d$ and, for $r \in [3 \sqrt{d}, R_0]$, let $Q_r$ denote as before the maximal cube consisting of unit cubes centered on $\mathbb{Z}^d$ which is contained in $B_{r/2}(0)$. Then let
\begin{equation}
    P_r := P\left( \left\{ \text{Card}\{ j \in Q_r \cap \mathbb{Z}^d : \omega_j \leq c_P r^{-2} \} \geq (1 - \lambda) |Q_r| \right\} \right).
\end{equation}
Also define a similar quantity for the whole domain, i.e.,
\begin{equation}
    P_\Omega = P\left( \left\{ \text{Card}\{ j \in \Omega \cap \mathbb{Z}^d : \omega_j \leq c_P R_0^{-2} \} \geq (1 - \lambda) |\Omega| \right\} \right).
\end{equation}
Finally, for $3 \sqrt{d} \leq r < R_0$, set $r_k = (1 + \varepsilon)^k/2 r$ for $0 \leq k \leq k_{\text{max}}$, where $k_{\text{max}}$ is the largest integer such that $r_k < R_0$. Then
\begin{equation}
    P\left( \left\{ \sup_{\xi \in B_{r/3}(0)} u(\xi) \geq Mr^2 \right\} \right) \leq P_\Omega + C e^{-d} \sum_{0 \leq k \leq k_{\text{max}}} P_{r_k},
\end{equation}
where $C$ depends only on the dimension.

Here we shall not even need our assumption that the probability distribution $F$ of (3.3) is not concentrated at one point and $F(\delta) > 0$ for $\delta > 0$; we will evaluate the probabilities later.

We wrote our estimates with all the cubes $Q_r$, and our test ball $B_{r/3}(0)$, all centered at 0, but since the $\omega_j$ are i.i.d. variables and our problem is invariant under translations by $\mathbb{Z}^d$, the various probabilities mentioned in the statement would be the same with all the cubes (and the test ball) centered anywhere else on $\mathbb{Z}^d$. We will also use this invariance during the proof.

**Proof.** The idea is to repeatedly use Lemma 3.11 and stop when the resulting ball exceeds the size of $\Omega$. 

Let \( r \) be given, suppose that \( \sup_{x \in B_{r/\sqrt{3}}(0)} u(x) \geq Mr^2 \); we pick \( \bar{x}_0 \in B_{r/3}(0) \) such that \( u(\bar{x}_0) \geq Mr^2 \), and try to use Lemma 3.11 repeatedly to find points \( \bar{x}_j \) such that \( u(\bar{x}_j) \geq Mr^2 \), and to try to use Lemma 3.11 repeatedly to find points \( \bar{x}_j \) with \( u(\bar{x}_j) \) always larger. Set (for later coherence of notation) \( Q_0 = Q_r \). One possibility is that (3.12) fails (with this choice of \( Q_r \)); we call this event \( \mathfrak{A}_0 \). But suppose not; then Lemma 3.11 gives a point \( \bar{x}_1 \in B_{r/3}(\bar{x}_0) \), with \( r_1 = (1 + \varepsilon)\sqrt{3} r \); as above, such that \( u(\bar{x}_1) \geq (1 + \varepsilon)u(\bar{x}_0) \), as in (3.14).

Notice that \( u(\bar{x}_1) \geq Mr^2 \), so we can try to apply Lemma 3.11 again. This time, it could be that \( \bar{x}_1 \notin B_{r/3}(0) \), so we choose \( \bar{x}_1 \in \mathbb{Z}^d \) such that \( \bar{x}_1 - \bar{x}_1 \in B_{r/3}(0) \), and apply the lemma after translating by \( \bar{x}_1 \). We will need to be more specific later about how we choose \( \bar{x}_1 \), but for the moment let us not bother. This means that the role of \( Q_r \) is now played by \( Q_1 = \bar{x}_1 + Q_{r_1} \). One possibility is that (3.12) fails for \( Q_1 \); we call this event \( \mathfrak{A}_1 \). But we assume not for the moment, and the lemma gives a new point \( \bar{x}_2 \in B_{r/3}(\bar{x}_1) \) such that \( u(\bar{x}_2) \geq (1 + \varepsilon)u(\bar{x}_1) \), as in (3.14). Then \( u(\bar{x}_2) \geq Mr^2 \) and we can try to apply Lemma 3.11 again.

We continue as long as we do not encounter an event \( \mathfrak{A}_k \) where (3.12) fails for \( Q_k \), and then we end with a last application for \( k_{\text{max}} \), which gives a point \( \bar{x}_{k_{\text{max}}+1} \) such that \( u(\bar{x}_{k_{\text{max}}+1}) \geq M r_{k_{\text{max}}+1}^2 \geq MR_{\text{max}}^2 \). Let \( \bar{x}_{\text{max}} \in \Omega \) be such that \( u(\bar{x}_{\text{max}}) = ||u||_{\text{max}} \), and notice that \( u(\bar{x}_{\text{max}}) \geq MR_{\text{max}}^2 \). We now try to apply Lemma 3.11 one last time, to the point \( \bar{x}_{\text{max}} \), but for this it will be convenient to enlarge our domain.

Suppose for definiteness that our fundamental domain \( \Omega \) (we abuse notation a little, and give it the same name as \( \mathbb{R}^d / R_0 \mathbb{Z}^d \)) is the cube of sideldength \( R_0 \) centered at the origin; we know that, due to our periodic conditions, other choices would be equivalent, but with this choice we were able to state and prove Lemma 3.11 without crossing the boundary. Pick an odd integer \( N \) larger than \( 4 \sqrt{d} \), and denote by \( \tilde{\Omega} \) the cube centered at the origin and with sideldength \( NR_0 \); thus \( \tilde{\Omega} \) is composed of \( \Omega \), plus a certain number of translated copies. Extend \( V \) and \( u \) to be \( R_0 \mathbb{Z}^d \)-periodic. Then the extension of \( u \) still satisfies \( Lu = 1 \) on \( \tilde{\Omega} \), and by uniqueness it is the landscape function associated to \( \tilde{\Omega} \) and periodic boundary conditions. We apply Lemma 3.11 with this new, larger domain, and the radius \( r = 2 \sqrt{d} R_0 \), so that the corresponding cube \( Q_r \) is precisely \( \tilde{\Omega} \). Our choice of \( N \) is large enough for this to be possible, and also we may assume, since our problem is invariant by translations from \( \mathbb{Z}^d \), that \( \bar{x}_{\text{max}} \in B_{r/3}(0) \). Our last bad event \( \mathfrak{A}_{k_{\text{max}}+1} \) is when (3.12) fails for \( Q_r = \tilde{\Omega} \), and if this does not happen, we get a new point \( \bar{x} \in \tilde{\Omega} \) such that \( u(\bar{x}) \geq (1 + \varepsilon)u(\bar{x}_{\text{max}}) \). This is impossible, because \( u(\bar{x}_{\text{max}}) = ||u||_{\text{max}} \) and \( u \) takes the same values on \( \tilde{\Omega} \) as on \( \Omega \).

At this point we proved that if the event of the left-hand side of (3.37) occurs (i.e., we can find \( \bar{x}_0 \) as above, with \( u(\bar{x}_0) \geq Mr^2 \)), then one of the bad events \( \mathfrak{A}_k \) occurs. What we just need to do now is check that the probability of each event \( \mathfrak{A}_k \) is at most the corresponding term of the right-hand side of (3.37). In particular, we
do not need to check anything about the independence of these events, we just add their probability.

In our last case we made sure that \( Q_r = \Omega \) precisely, and so this is almost the definition (compare (3.36) with (3.12)); there is a small discrepancy, due to the fact that since \( r = 2 \sqrt{d} R_0 \) here, we should have said

\[
\omega_j \leq C_p (2 \sqrt{d} R_0)^{-2}
\] rather than \( \omega_j \leq C_p R_0^{-2} \), but the difference only amounts to making \( C_p \) a little larger, which is not a problem, and we prefer the less sharp, but simpler form in (3.36).

For \( 0 \leq k \leq k_{\max} \), we need to evaluate the probability of the event \( \mathcal{A}_k \), but we have to be a little careful, because we only know that (3.12) fails for the translated cube \( Q_k = \xi_k + Q_r \), but a priori we do not know which cube this is. Given the position of \( \xi_0 \in B(r/3)(0) \), and the fact that for \( 0 \leq m < k \), \( |\xi_{m+1} - \xi_m| \leq r_{m+1} \), we see that \( |\xi_k| \leq \sum_{m=1}^k r_m \leq C e^{-1} r_k \). We need to find \( \xi_k \in \mathbb{Z}^d \) such that \( |\xi_k - \xi_{\ell_k}| \leq r_k/3 \), so we can choose \( \xi_k \) in some set \( \Xi_k \), known in advance, with less than \( C e^{-d} \) elements. Our event \( \mathcal{A}_k \) can only happen if (3.12) fails for one of the cubes \( \xi_k + Q_r \), \( \xi \in \Xi_k \), and the total probability that this happens is at most \( C e^{-d} \) (all the smaller events associated to a single \( \xi \in \Xi_k \) have the same probability \( \mathbb{P}(r_k) \), because our \( \omega_j \) are i.i.d.). This completes the proof of Lemma 3.34.

\[ \square \]

**Lemma 3.38.** Let \( Q \) be some cube in \( \mathbb{R}^d \) and assume that the \( \omega_j, j \in \mathbb{Z}^d \cap Q \), are i.i.d. variables taking values \( 0 \leq \omega_j \leq 1 \), with a probability distribution

\[
F(\delta) = \mathbb{P}(\omega \leq \delta), \quad 0 \leq \delta \leq 1,
\]

which is not trivial, i.e., not concentrated at one point, and such that 0 is the infimum of the support.

Fix \( 0 < \mu < 1 \), \( c_p > 0 \), and consider \( r > 0 \) such that \( \mu - F(c_p r^{-2}) > 0 \). Then such that

\[
\mathbb{P} \left( \left\{ \text{Card } \{ j \in Q \cap \mathbb{Z}^d : \omega_j \leq c_p r^{-2} \} \geq \mu \text{ Card } (Q \cap \mathbb{Z}^d) \right\} \right) \leq \left( H(\mu) F(c_p r^{-2})^\mu \right) \text{Card } (Q \cap \mathbb{Z}^d)
\]

with \( H(\mu) = (\mu^\mu (1 - \mu)^{1-\mu})^{-1} \).

While we intend to use the Lemma for \( \mathbb{P}_r \) and \( \mathbb{P}_\Omega \) from Lemma 3.34, we chose to state it in full generality to emphasize explicit dependence on the constants which could be useful in other contexts. Also, observe that

\[
\lim_{\mu \to 1} H(\mu) = 1;
\]

we will be able to choose \( \mu \) so close to 1, depending on \( \mathbb{E}(\omega) \) and the dimension only, that \( H(\mu) F(c_p r^{-2})^\mu < F(c_p r^{-2})^{1/2} \), at least for \( r \) sufficiently large, also depending on \( \mathbb{E}(\omega) \) and the dimension only.
Proof. Let $P$ denote the left-hand side of (3.39), and define the random variables $\xi_j$ equal to 1 when $\omega_j \leq c_p r^{-2}$ and 0 otherwise. By our assumptions the $\xi_j$ are independent and identically distributed. Furthermore,

$$P = \mathbb{P}\left(\sum_{j \in Q \cap \mathbb{Z}^d} \xi_j \geq \mu \text{ Card } \{Q \cap \mathbb{Z}^d\}\right),$$

hence for any $t > 0$,

$$P = \mathbb{P}\left(\left\{e^{\sum_{j \in Q \cap \mathbb{Z}^d} \xi_j} \geq e^{\mu \text{ Card } \{Q \cap \mathbb{Z}^d\}}\right\}\right) \leq e^{-\mu \text{ Card } \{Q \cap \mathbb{Z}^d\}} A,$$

by Chebyshev’s inequality, and where $A$ is the expectation of the product of independent identically distributed variables $e^{\xi_j}$, hence $A = A_0^{\text{ Card } \{Q \cap \mathbb{Z}^d\}}$, where $A_0$ is the expectation of any of the $e^{\xi_j}$. That is,

$$A_0 = e^{\mathbb{P}((\omega_j \leq c_p r^{-2}))} + \mathbb{P}((\omega_j > c_p r^{-2})) = e^F(c_p r^{-2}) + 1 - F(c_p r^{-2})$$

and, by (3.41),

$$P \leq \exp\left(-\text{Card } \{Q \cap \mathbb{Z}^d\}(t\mu - \log A_0)\right)$$

for every $t > 0$. We now want to optimize in $t$, but let us introduce notation before we compute. Set $N = \text{ Card } \{Q \cap \mathbb{Z}^d\}$, $F = F(c_p r^{-2})$ (two constants) and, for $t > 0$,

$$f(t) := t\mu - \log A_0 = t\mu - \log(e^F + 1 - F).$$

Thus $P \leq e^{-N f(t)}$, and we study $f$. First, $f(0) = 0$, and $f'(t) = \mu - \frac{e^F}{e^F + 1 - F}$. Thus $f'(0) = \mu - F = \mu - F(c_p r^{-2}) > 0$ by our assumptions, and hence $f$ is increasing near 0. In fact, $f'$ only vanishes at the point $t^*$ such that

$$e^{f'} = \frac{\mu}{1 - \mu} \frac{1 - F}{F}$$

(notice that this last value is $> 1$ since $\mu > F$). Since we strongly expect $f(t)$ to be minimal for $t = t^*$, we decide to take $t = t^*$ in the inequality above. This yields

$$P \leq e^{-N f(t^*)} = e^{-N \mu + N \log(e^F + 1 - F))}$$

$$= \exp\left(-N \mu \log\left(\frac{\mu}{1 - \mu} \frac{1 - F}{F}\right) + N \log\left(\frac{1 - F}{1 - \mu}\right)\right)$$

$$= \exp\left(-N \mu \log\left(\frac{\mu}{1 - \mu} \frac{1 - F}{F}\right) + N \log\left(\frac{1 - F}{1 - \mu}\right)\right)$$

$$= \exp\left(-N \log\left(\frac{\mu^F (1 - \mu)^{1-\mu}}{F^F (1 - F)^{1-\mu}}\right)\right) = \left(\frac{F^\mu (1 - F)^{1-\mu}}{\mu^\mu (1 - \mu)^{1-\mu}}\right)^N.$$

We may drop $(1 - F)^{1-\mu} \leq 1$, and now this is the same thing as (3.39); Lemma 3.38 follows. \qed
**Corollary 3.43.** Let $\Omega$, $L$, and $V$ be as in Theorem 3.1. There exist constants $R^*, c_P, M, \gamma_1, \gamma_2$, depending only on the dimension and the common expectation of the random variables $\omega_j$, such that

\[
P \{ u(\xi_0) \geq M r^2 \} \leq \gamma_1 F(c_P r^{-2})^{\gamma_2 r^d}
\]

for any $\xi_0 \in \Omega$ and any $r \in (R^*, R_0]$.

**Proof.** This will follow from a combination of Lemmas 3.34 and 3.38. First recall our assumption that the measure associated to $F$ (call it $\nu$) is nontrivial. Let $\mathbb{E}(\omega)$ denote the expectation of our random variables; then

\[
0 < \mathbb{E}(\omega) < 1.
\]

where the first inequality holds because $\nu$ is not a Dirac mass at the origin, and second one holds because the support of $\nu$ touches 0 and is contained in $[0, 1]$.

Furthermore notice that $\mathbb{E}(\omega) = \int_{[0,1]} \delta d\nu(\delta) = \int_{[0,1]} \delta d\nu(\delta) \leq 1 - \nu([0])$ by Chebyshev’s inequality, so $F(0) = \nu([0]) \leq 1 - \mathbb{E}(\omega) < 1$. Clearly, $F(c_P r^{-2})$ decays as $r$ grows. We choose a value of $F(c_P r^{-2})$ that we don’t want to exceed, half of the way between $1 - \mathbb{E}(\omega)$ and 1, i.e., $F_0 = \frac{2 - \mathbb{E}(\omega)}{2} < 1$, choose (we shall see why soon) $a = \frac{\mathbb{E}(\omega)}{2 - \mathbb{E}(\omega)} \in (0, 1)$, and check now that

\[
F(a) \leq F_0 = \frac{2 - \mathbb{E}(\omega)}{2}.
\]

Indeed $\mathbb{E}(\omega) = \int_{[0,1]} x dv(x) \leq a\nu([0,a]) + \nu(a, 1] = aF(a) + 1 - F(a)$, hence $F(a)(1 - a) \leq 1 - \mathbb{E}(\omega)$ and since $1 - a = \frac{2 - 2\mathbb{E}(\omega)}{2 - \mathbb{E}(\omega)}$, we get (3.46).

Now let $\mu \in (3/4, 1)$ be given, to be chosen soon in terms of $F_0$, very close to 1. Also set $\lambda = 1 - \mu$ (small), and with this $\lambda$, define $c_P = c_P(\mu, \lambda, d)$ large enough, as in Lemma 3.11, and choose $\varepsilon = \varepsilon(\lambda, d) > 0$ small enough, and $M = M(\varepsilon, \lambda, d)$ large enough, again as in Lemma 3.11. Those choices also work for Lemma 3.34, so we will be able to apply these two lemmas with these constants.

We choose $R^*$ so large that $c_P(R^*)^{-2} \leq a$; $R^*$ depends on $\lambda$ and $\mu$, but soon we will be able to choose $\mu$ (and hence, $\lambda$), that depends only on $\mathbb{E}(\omega)$ and the dimension, so eventually $R^*$ will depend only on $\mathbb{E}(\omega)$ and the dimension as well. With this choice of $R^*$, and since we shall always restrict to radii $r \geq R^*$, we will get that

\[
F(c_P r^{-2}) \leq F(c_P(R^*)^{-2}) \leq F(a) \leq F_0 := \frac{2 - \mathbb{E}(\omega)}{2}.
\]

The whole point of Lemma 3.38 was to give a bound on the probability $\mathbb{P}_r$ of (3.35), and this bound is

\[
\mathbb{P}_r \leq \left( H(\mu) F(c_P r^{-2})^\mu \right)^N,
\]

with $N = \text{Card} \{ Q \cap \mathbb{Z}^d \}$. Notice that we can take $c_P^* = c_P$, and the assumption that $F(c_P r^{-2}) < \mu$ is satisfied by (3.47) if we take $\mu > F_0$. We also take $\mu > 3/4$, so that
\[ F(c_pr^{-2})^{-\mu-1/2} \leq F_0^{-\mu-1/2} \leq F_0^{1/4} \] and use (3.40) to finally choose \( \mu \) so close to 1 that \( H(\mu)F_0^{1/4} < 1 \). This way (3.48) implies that \( \mathbb{P}_r \leq F(c_pr^{-2})^{N/2} \), which will be good enough for us.

Now let \( r \geq R' \) be given, and let us evaluate the probability (call it \( P \)) of (3.44). Notice that \( P \) is smaller than the probability of having \( u(\xi) \geq Mr^2 \) for some point of a cube \( S \) of size roughly \((10^d)^{-1}r\), say, that contains \( \xi_0 \). This probability does not depend on \( S \) (by invariance), and can be estimated as in Lemma 3.34. Thus we get that

\[ P \leq \mathbb{P}_\Omega + C\varepsilon^{-d} \sum_{0 \leq k \leq k_{\max}} \mathbb{P}_r, \]

with \( r_k = (1 + \varepsilon)^{k/2}r \). We use (the consequence of) (3.48) to estimate \( \mathbb{P}_r \), noticing that \( F(c_pr_k^{-2}) \leq F(c_pr^{-2}) \) and each set \( Q_{r_k} \cap \mathbb{Z}^d \) has at least one more point than the previous one. That is, \( N_k = \text{Card}(Q_{r_k} \cap \mathbb{Z}^d) \) is at least \( N + k \), where \( N = \text{Card}(Q_r \cap \mathbb{Z}^d) \). Then \( \mathbb{P}_r \leq F(c_pr_k^{-2})^{N_k/2} \leq F(c_pr_k^{-2})^{(N+k)/2} \leq F_0^{1/2} F(c_pr^{-2})^{N/2} \).

We have a similar estimate for \( \mathbb{P}_\Omega \) (which is of the same type as \( \mathbb{P}_r \), with \( r_k \sim R_0 \)). So we can sum the geometric series, and get the more precise estimate

(3.49) \[ P \leq \gamma_1 F(c_pr^{-2}) \text{Card}(Q_r \cap \mathbb{Z}^d)^{1/2} \leq \gamma_1 F(c_pr^{-2})^{d/2} \]

with constants \( \gamma_1 \) and \( \gamma_2 \) that depend on \( d \) and \( \mathbb{P}(\omega) \) (through our choice of \( F_0, a, \mu \), and then the various constants that ensue, including \( \varepsilon \)). As was said earlier, we can then compute \( R^* \), depending on these constants. Corollary 3.43 follows. \( \square \)

**Corollary 3.50.** Let \( \Omega, L, \) and \( V \) be as in Theorem 3.1, in particular \( V \) is a random potential governed by i.i.d. random variables \( \omega_j \). Then there exist constants \( \mu^*, M, c_p, \gamma_3, \gamma_4 \), depending only on the dimension and the expectation of the \( \omega_j \),

(3.51) \[ N_u^E(\mu) \leq \gamma_3 \mu^{d/2} F(Mc_p \mu)^{\gamma_4 \mu^{-d/2}}, \]

whenever \( \mu < \mu^* \) and \( R_0 > (\mu M)^{-1/2} \).

**Proof.** Recall from (1.6) and the statement of Theorem 1.13 that

\[ N_u^E(\mu) = \frac{1}{|\Omega|} \times \mathbb{E}\left\{ \text{the number of cubes } Q \in \{Q\}_{k \mu^{-1/2}} \text{ such that } \min \frac{1}{Q} \leq \mu \right\}, \]

where \( 1 \leq k < 2 \) (depending on \( \mu \)) is the smallest number such that \( R_0 \) is an integer multiple of \( k \mu^{-1/2} \). The expectation of the number of cubes is less than the sum of expectations (by the triangle inequality), so

\[ N_u^E(\mu) \leq \frac{1}{|\Omega|} \frac{|\Omega|}{(\kappa \mu^{-1/2})^d} \sup_{Q \in \{Q\}_{k \mu^{-1/2}}} \mathbb{P}\left\{ \min \frac{1}{Q} \leq \mu \right\}. \]

We want to apply our estimate in (3.49), coming from Lemma 3.34. This one gives the probability that the infimum of \( \frac{1}{Q} \) on \( B_{1/3}(0) \) is at most \((Mr^2)^{-1} \), so we should take \( r \) such that \((Mr^2)^{-1} = \mu \). Notice that \( r \leq R_0 \) by our condition on \( R_0 \). We get
equal probabilities for integer translations of that ball, as usual, by the translation invariance of our setting. Now each cube \( Q \in \{Q\}_{\kappa^{1/2}} \) can be covered by less than \( C \) integer translations of of \( B_{r/3}(r/30) \) (taken from a fixed subgrid), and for each one the probability that \( \frac{1}{u} \leq \mu \) somewhere on the ball is estimated as in (3.49). Therefore

\[
N_\mu^E(\mu) \leq C(\kappa \mu^{-1/2})^{-d} \gamma_1 F(c_P r^{-2})^{-d} \leq \gamma_3 \mu^{d/2} F(M c_P \mu)^{\gamma_4 \mu^{-d/2}},
\]

as announced. \( \square \)

We now give a lower bound for \( N_\mu^E(\mu) \).

**Lemma 3.52.** Let \( \Omega, L, \) and \( V \) be as in Theorem 3.1 and in the previous lemmas. There exist constants \( m, \bar{c}_p, \gamma_5, \gamma_6 \), depending on the dimension only, such that

\[
(3.53) \quad N_\mu^E(\mu) \geq \gamma_5 \mu^{d/2} F(\bar{c}_p \mu)^{\gamma_6 \mu^{-d/2}},
\]

whenever \( \mu \leq 1 \) and \( R_0 > (\mu m)^{-1/2} \).

**Proof.** Much as above, we start observing that

\[
(3.54) \quad N_\mu^E(\mu) = \frac{1}{|\Omega|} \times \mathbb{P} \left\{ \text{the number of cubes } Q \in \{Q\}_{\kappa^{1/2}} \text{ such that } \min_{Q} \frac{1}{u} \leq \mu \right\}
\]

\[
(3.55) \quad \geq \frac{1}{|\Omega|} \times \sum_{Q \in \{Q\}_{\kappa^{1/2}}} \mathbb{P} \left\{ \min_{Q} \frac{1}{u} \leq \mu \right\}.
\]

Now we recall again from from [ADFJM1], Lemma 4.1 (or (1.3)), that

\[
\int_{\Omega} |\nabla f|^2 + V f^2 \, dx \geq \int_{\Omega} \frac{1}{u} f^2 \, dx,
\]

for all \( f \) in the space of periodic functions in \( W^{1,2}(\Omega) \), and in particular for \( f \in C_0^\infty(\Omega) \). We will choose \( f \) to be a standard cut-off on \( 4C_1 \Omega \), \( C_1 \geq 1 \); that is, \( f \in C_0^\infty(4C_1 \Omega) \), \( f = 1 \) on \( C_1 \Omega \) and \( |\nabla f| \leq (C_1 l(\Omega))^{-1} \). We will need that \( 4C_1 \Omega \subset \Omega \), i.e., \( \Omega \) should be large enough to accommodate this. This is ensured by the condition \( R_0 > (\mu m)^{-1/2} \) if \( m \) is small enough. It follows that

\[
\min_{C_1 \Omega} \frac{1}{|C_1 \Omega|} \left( \frac{1}{C_1 \Omega} \int |\nabla f|^2 \right) \leq \frac{1}{|C_1 \Omega|} \left( \int_{\Omega} |\nabla f|^2 + V f^2 \right) \leq \frac{1}{|C_1 \Omega|} \left( \int_{4C_1 \Omega} (C_1 l(\Omega))^{-2} + V \right) \leq \frac{4^d(C_1 l(\Omega))^{-2} + \int_{4C_1 \Omega} V}{4C_1 \Omega}.
\]

We choose \( C_1 \) such that \( 4^d C_1^2 \leq 1/2 \); then \( 4^d(C_1 l(\Omega))^{-2} \leq l(\Omega)^{-2}/2 = \kappa^{-1} \mu/2 \leq \mu/2 \), and now \( \min_{C_1 \Omega} \frac{1}{u} \leq \mu/2 + 4^d \int_{4C_1 \Omega} V \). Therefore

\[
\mathbb{P} \left\{ \min_{C_1 \Omega} \frac{1}{u} \leq \mu \right\} \geq \mathbb{P} \left\{ 4^d \int_{4C_1 \Omega} V \leq \mu/2 \right\} \geq \mathbb{P} \left\{ \max_{4C_1 \Omega} V \leq 4^{-d} \mu/2 \right\}.
\]
Note that
\[
P \left\{ \min_{Q \in C_1} \frac{1}{u} \leq \mu \right\} \leq \sum_{Q' \in C_1 \cap Q} P \left\{ \min_{Q'} \frac{1}{u} \leq \mu \right\}.
\]

Therefore,
\[
\sum_{Q \in \{Q\}} P \left\{ \min_{Q} \frac{1}{u} \leq \mu \right\} \leq \sum_{Q \in \{Q\}} \sum_{Q' \in C_1 \cap Q} P \left\{ \min_{Q'} \frac{1}{u} \leq \mu \right\} \leq C^d_1 \sum_{Q \in \{Q\}} P \left\{ \min_{Q} \frac{1}{u} \leq \mu \right\}.
\]

Combining all of the above and using the independence of the \(\omega_j\), we conclude that
\[
\sum_{Q \in \{Q\}} P \left\{ \min_{Q} \frac{1}{u} \leq \mu \right\} \geq C^{-d}_1 \sum_{Q \in \{Q\}} P \left\{ \omega_j \leq 4^{-d} \mu / 2 \forall j \in 5C_1 Q \cap \mathbb{Z}^d \right\} = C^{-d}_1 \left| \frac{|Q|}{(\kappa \mu^{-1/2})^d} \right| F \left( 4^{-d} \mu / 2 \right)^{\text{card} \{5C_1 Q \cap \mathbb{Z}^d\}},
\]
which yields the desired conclusion. \(\square\)

We are now finished with the proof of Theorem 3.1, which is a combination of Corollary 3.50 and Lemma 3.52. We just renamed the four \(\gamma_j\), and also renamed \(McP\) from Lemma 3.52 as \(cP\), but both of these constants depend only on \(d\) and the expectation of the \(\omega_j\).

We shall now see how Theorem 3.1 provides the desired estimates on the expectation of the density of states.

**Theorem 3.56.** Let \(\Omega, L,\) and \(V\) be as in Theorems 1.13 and 3.1. Then there exist constants \(C_5, C_6 > 0\), depending on the dimension and the expectation of the random variables \(\omega_j\), only and a constant \(C_4 > 0\), depending on the dimension only, such that
\[
(3.57) \quad C_5 N^E_\mu (C_6 \mu) \leq N^E(\mu) \leq N^E_\mu (C_4 \mu),
\]
for every \(\mu > 0\).

In particular, there exist constants \(\mu^*, m_1, c_P, \gamma_1, \gamma_2\), depending on the dimension and the expectation of the random variable only, and constants \(\tilde{c}_p, \gamma_3, \gamma_4\), depending on the dimension only, such that
\[
(3.58) \quad \gamma_3 \mu^{d/2} F(\tilde{c}_p \mu)^{\gamma_3 \mu^{-d/2}} \leq N^E(\mu) \leq \gamma_1 \mu^{d/2} F(c_p \mu)^{\gamma_1 \mu^{-d/2}},
\]
whenever \(\mu < \mu^*\) and \(R_0 > (\mu m_1)^{-1/2}\).
Notice that Theorem 3.56 is a combination of Theorem 1.13 and the statement (3.6) in Theorem 3.5. Since the other part of Theorem 3.5, (3.7), was proved in Theorem 3.1, both Theorems 1.13 and 3.5 will follow as soon as we prove Theorem 3.56.

Proof. The right-hand side inequality in (3.57) is the right-hand side inequality in (1.8), hence it has been proved in Theorem 1.7. The proof of the left-hand side of (1.8) will be split into two parts, where $\mu > \mu^\#$ and $\mu \leq \mu^\#$ for some suitable $\mu^\#$.

For the values of $\mu > \mu^\#$ we are going to proceed as for the proof of (1.11) in Theorem 1.7, and prove that for any given $\mu_0$,

$$N_u(\mu) \leq N(C'\mu) \quad \text{for all } \mu > \mu_0,$$

where $C' = (d, \mu_0)$ depends only on $\mu_0$ and the dimension. We will essentially use the fact that the function $u^2$ is a doubling weight. Indeed, given that $\|V\|_{L^\infty(\Omega)} \leq 1$, the Harnack inequality (see, [GT], Theorem 8.17 and 8.18) guarantees that

$$\sup_{Q_{2s}} u \leq C(s) \left( \inf_{Q_s} u + s^2 \right).$$

Here the constant $C(s)$ depends on $s$; specifically, the examination of the proof shows that $C(s) \leq C_0$ for some dimensional constant $C_0$ (see the comment right after the statement of Theorem 8.20 in [GT] to this effect or simply use the Harnack inequality at scale 1 roughly $s$ times to treat larger $s$). Hence, if $s$ is bounded from above by some constant depending on $d$ and some $\mu_0 > 0$, we have

$$\sup_{Q_{2s}} u \leq C(d, \mu_0) \left( \inf_{Q_s} u + s^2 \right).$$

Going further, we recall that $u \geq 1$ on $\Omega$ (see [ADFJM1], Proposition 3.2), so that possibly further adjusting $C(d, \mu_0)$ we have

$$\sup_{Q_{2s}} u \leq C(d, \mu_0) \inf_{Q_s} u,$$

again assuming that $s$ is bounded from above by some constant depending on $d$ and $\mu_0$. We now follow the argument in (2.2)–(2.7), except that this time we take $C_2 = 1$. Then the sidelength of the cube under consideration is $\kappa \mu^{-1/2} \leq 2(\mu_0)^{-1/2}$, and we will be using doubling on cubes of the size at most $16(\mu_0)^{-1/2}$ (in fact, we even use smaller $\kappa$). The argument follows the same path, only arriving at the bound by some constant $C'(d, \mu_0) \mu$ in place of $C_{d,5}C_2\mu$ on the right-hand side of (2.7). Thus (3.59) holds: $N_u(\mu) \leq N(C'(d, \mu_0)\mu)$, for all $\mu > \mu_0$. We can write an upper bound on $C'(d, \mu_0) \mu$ in the form $e^{\tilde{C} \mu_0^{1/2}}$ explicitly, for a suitable dimensional constant $\tilde{C}$.

Note that $\mu_0 e^{\tilde{C} \mu_0^{1/2}} \to \infty$ either as $\mu_0 \to 0$ or as $\mu_0 \to \infty$. Therefore, we choose

$$\mu^\# = \min_{\mu_0>0} \mu_0 e^{\tilde{C} \mu_0^{1/2}}$$

(3.60)
and choose \( \mu_0 \) to attain the minimum. In other words,

\[
N_\mu(C'(d, \mu_0)^{-1}) \leq N(\mu),
\]

for all \( \mu > \mu^* = \mu_0 C'(d, \mu_0) \).

Now recall the first inequality in (1.8) of Theorem 1.7 and fix the constants \( C_1, C_2, C_3 \) (depending on dimension only) from this inequality. For the \( \mu^* \) given as above, we claim that for a suitable choice of \( \alpha < 2^{-d} \), depending on dimension and the expectation of the \( \omega_i \), and also depending on \( \mu^* \),

\[
C_3 N^E_\mu(C_2\alpha^{d+4}\mu) \leq \frac{1}{2} C_1 \alpha^d N^E_\mu(C_2\alpha^{d+2}\mu),
\]

whenever \( \mu < \mu^* \) and \( R_0 > (\mu m_1)^{-1/2} \) (for some \( m_1 > 0 \), that depends on the dimension and the expectation of the \( \omega_j \) only). As we shall see, this is basically a consequence of the fact that according to Theorem 3.1, \( N^E_\mu(\mu) \) is exponentially small for small \( \mu \), far beating the polynomial increase of \( \alpha^{-d/2} \). Indeed, Theorem 3.1 says that

\[
N^E_\mu(C_2\alpha^{d+4}\mu) \leq \gamma_1 (C_2\alpha^{d+4}\mu)^{d/2} F(c_p C_2\alpha^{d+4}\mu)^{\nu(C(C_2\alpha^{d+4}\mu)^{d/2})},
\]

provided that \( (C_2\alpha^{d+4}\mu) < \mu^* \) and \( R_0 > (C_2\alpha^{d+4}\mu m)^{-1/2} \). These last conditions are ensured if we take \( C_2\alpha^{d+4}\mu^* \leq \mu^* \) and \( m_1 \leq C_2\alpha^{d+4}m \). Theorem 3.1 also says that

\[
N^E_\mu(C_2\alpha^{d+2}\mu) \geq \gamma_3 (C_2\alpha^{d+2}\mu)^{d/2} F(c_p C_2\alpha^{d+2}\mu)^{\nu(C(C_2\alpha^{d+2}\mu)^{d/2})},
\]

provided that \( (C_2\alpha^{d+2}\mu) < \mu^* \) and \( R_0 > (C_2\alpha^{d+2}\mu m)^{-1/2} \), which will hold if we take \( C_2\alpha^{d+2}\mu^* \leq \mu^* \) and \( m_1 \leq C_2\alpha^{d+2}m \).

Set \( F_2 = F(c_p C_2\alpha^{d+2}\mu) F_4 = F(c_p C_2\alpha^{d+4}\mu) \); if we want to prove our claim (3.61), it is enough to prove that

\[
C_3 \gamma_1 (C_2\alpha^{d+4}\mu)^{d/2} F_{4\gamma(C(C_2\alpha^{d+4}\mu)^{d/2})} \leq \frac{1}{2} C_1 \alpha^d \gamma_3 (C_2\alpha^{d+2}\mu)^{d/2} F_4^{\nu(C(C_2\alpha^{d+2}\mu)^{d/2})}.
\]

Take \( \alpha \) so small that \( c_p C_2\alpha^{d+4} < \tilde{c} p C_2\alpha^{d+2} \), thus \( \alpha \) depends also on the expectation of \( \omega \), through \( \gamma_5 \). Then \( F_4 \leq F_2 \). Also choose \( \alpha \) so small that \( \tilde{c} p C_2\alpha^{d+2}\mu^* < \delta_0 \), with \( \delta_0 = \mathbb{E}(\omega)/2 \). This way, if \( \nu \) denotes the probability measure defined by \( F \), \( \mathbb{E}(\omega) = \int_{[0,1]} \delta d\nu(\delta) = \delta_0 + \nu([\delta_0, 1]) = \delta_0 + 1 - F(\delta_0) \), so \( F(\delta_0) \leq 1 - \mathbb{E}(\omega)/2 < 1 \).

Therefore \( F_4 \leq F_2 \leq 1 - \mathbb{E}(\omega)/2 \) in the estimates above; now

\[
\frac{F_4^{\nu(C(C_2\alpha^{d+4}\mu)^{d/2})}}{F_2^{\nu(C(C_2\alpha^{d+4}\mu)^{d/2})}} \leq F_2^{\nu(\mu^{d/2})},
\]

with \( a = \gamma_2 (C_2\alpha^{d+4}a)^{d/2} - \gamma_4 (C_2\alpha^{d+2}a)^{d/2} \geq \frac{1}{2} \gamma_2 (C_2\alpha^{d+4})^{d/2} \) if \( \alpha \leq (\gamma_4/\gamma_2)^{1/2} \). Thus the right-hand side of (3.65) is exponentially decreasing when \( \alpha \) tends to 0. The powers of \( \mu \) in (3.64) are the same, and the rest is polynomial in \( \alpha \); thus (3.64) holds for \( \alpha \) small, and (3.61) follows.
Now we average (1.8) and use (3.61); we get that

\[(3.66)\]

\[
\frac{C_1}{2} \alpha^d N_u^e (C_2 \alpha^{d+2} \mu) \leq N_u^e (\mu) \leq N_u^e (C_4 \mu),
\]

which is the same as (3.57) (recall that we are allowed to let \(C_5\) and \(C_6\) depend on \(\alpha\), which is now chosen depending on \(\mathcal{P}(\omega)\) and \(d\)), except that we have to assume that \(\mu < \mu^\#\) and \(R_0 > (m_1 \mu)^{-1/2}\), and

\[(3.67)\]

\[
\alpha = \min \left\{ \left( \frac{\mu^\#}{C_2 \mu^\#} \right)^{\frac{1}{d+2}}, \left( \frac{\delta_0}{C_2 \mu^\#} \right)^{\frac{1}{d+2}}, \left( \frac{\gamma_4}{\gamma_2} \right)^{\frac{1}{2}} \right\}
\]

Taken along with Theorem 3.1, this also automatically gives (3.58). As usual, we silently redefine the constants, still depending on the same parameters.

\[\square\]
