Escherichia coli of sequence type 3835 carrying $bla_{\text{NDM-1}}$, $bla_{\text{CTX-M-15}}$, $bla_{\text{CMY-42}}$ and $bla_{\text{SHV-12}}$

Yu Feng1,2,*, Ping Yang1,2,*, Yi Xie3, Xiaohui Wang1,2, Alan McNally5 & Zhiyong Zong1,2,4

New Delhi metallo-$\beta$-lactamase (NDM) represents a serious challenge for treatment and public health. A carbapenem-resistant $E$. coli clinical strain WCHEC13-8 was subjected to antimicrobial susceptibility tests, whole genome sequencing and conjugation experiments. It was resistant to imipenem (MIC, $>256\ \mu g/ml$) and meropenem (MIC, 128 $\mu g/ml$) and belonged to ST3835. $bla_{\text{NDM-1}}$ was the only carbapenemase gene detected. Strain WCHEC13-8 also had a plasmid-borne AmpC gene ($bla_{\text{CMY-42}}$) and two extended-spectrum $\beta$-lactamase genes ($bla_{\text{CTX-M-15}}$ and $bla_{\text{SHV-12}}$). $bla_{\text{NDM-1}}$ and $bla_{\text{SHV-12}}$ were carried by a 54-kb IncX3 self-transmissible plasmid, which is identical to plasmid pNDM-HF727 from $E$. cloacae. $bla_{\text{CMY-42}}$ was carried by a 64-kb IncI1 plasmid and $bla_{\text{CTX-M-15}}$ was located on a 141-kb plasmid with multiple F replicons (replicon type: F36:A4:B1). $bla_{\text{CMY-42}}$ was in a complicated context and the mobilisation of $bla_{\text{CMY-42}}$ was due to the transposition of $\text{ISEcp1}$ by misidentifying its right-end boundary. Genetic context of $bla_{\text{NDM-1}}$ in strain WCHEC13-8 was closely related to those on IncX3 plasmids in various $E$. coli species in China. In conclusion, a multidrug-resistant ST3835 $E$. coli clinical strain carrying $bla_{\text{NDM-1}}$, $bla_{\text{CTX-M-15}}$, $bla_{\text{CMY-42}}$ and $bla_{\text{SHV-12}}$ was identified. IncX3 plasmids may be making a significant contribution to the dissemination of $bla_{\text{NDM}}$ among $E$. coli species in China.

Carbapenems have long served as reliable and potent agents against Gram-negative bacilli. However, a variety of enzymes produced by bacteria are able to hydrolyse carbapenems, termed carbapenemases. New Delhi metallo-$\beta$-lactamase (NDM) is a type of carbapenemase and confers resistance to all $\beta$-lactams except monobactams1. NDM was first found in a $K$. pneumoniae isolate in 20082 and since then bacterial isolates producing NDM have been identified worldwide, representing a serious challenge for treatment, infection control and public health. In addition to India, China is a common place from which NDM-producing isolates are identified. In China, NDM was initially seen in $A$. baumannii3. but NDM-producing $E$. coli species have been increasingly reported4. Among carbapenem-resistant $E$. coli species in China, $K$. pneumoniae is the most common species with 10% of 12,121 clinical isolates collected from 16 major teaching hospitals in 2013 resistant to imipenem5. In contrast, carbapenem resistance is relatively uncommon in $E$. coli species in China and only 1% of 16,794 clinical isolates from the 16 hospitals in 2013 were resistant to imipenem5. During routine clinical duties, a carbapenem-resistant $E$. coli clinical isolate was encountered. This strain was then characterised and is reported here.
Results and Discussion

Clinical strain WCHEC13-8 was recovered on November 2012. This strain was identified as *E. coli* and was resistant to imipenem (Minimum inhibitory concentration [MICs], >256 μg/ml), meropenem (MIC, 128 μg/ml), ceftazidime (MIC, >256 μg/ml), ciprofloxacin (MIC, 256 μg/ml) but was intermediate to amikacin (MIC, 32 μg/ml) determined by the microdilution method. It was also resistant to ampicillin-sulbactam, aztreonam, cefazolin, cefepime, cefotaxime, ceftriaxone, gentamicin, piperacillin-tazobactam, tobramycin and trimethoprim-sulphamethoxazole determined by Vitek II. *bla*<sub>NDM</sub> was the only carbapenemase-encoding gene that was detected and sequencing the complete coding sequence of the gene revealed that it was *bla*<sub>NDM-1</sub>.

Strain WCHEC13-8 was subjected to whole genome sequencing on the Illumina HiSeq platform. A total of 7,149,960 reads and 643,496,400 bases were obtained from the genome sequencing with a 49.8% GC content. Reads were assembled to 268 contigs that were ≥500 bp in length (N50 metric, 118,912 bp) and contained 5,145,308 bp nucleotides. To identify whether strain WCHEC13-8 had any new genes or not, its genome sequence was compared to other *E. coli* genome sequences including 83 complete and 2,159 draft genomes available in GenBank. Despite comparing with such a large number of *E. coli* genomes, the strain still had three unique genes that were located on contigs belonging to the chromosome. Two of the three genes were clustered together and resided in the centre of a 149-kb large contig, which was part of the chromosome as it shows significant identity (74% coverage and 97% identity) with the chromosome of *E. coli* strain E2348/69 (GenBank accession number FM18568) identified using the BLAST program. The two novel genes encoded hypothetical proteins with 420 and 346 amino acids, respectively. Unfortunately, the function of the two hypothetical proteins were not able to be predicted using both Protein BLAST and InterProScan programs. The remaining unique gene was 2,976 bp on a new prophage region identified using the InterProScan program.

Strain WCHEC13-8 belonged to the phylogenetic group A and a new Sequence type (ST), ST3835 (adk-fumC-gyrB-icd-mdh-purA-recA allele numbers, 10-4-4-411-8-13-73). Multiple ST3835 isolates have been found in Korea in 2013, which is later than strain WCHEC13-8 (http://mlst.warwick.ac.uk/mlst/dbs/Ecoli). ST3835 has a single allele different from ST1284 (10-4-4-8-8-13-73) and ST3835 *E. coli* has been recovered from a human in Spain and from a dog in Germany (http://mlst.warwick.ac.uk/mlst/dbs/Ecoli). ST3835 belongs to the ST10 complex. Besides ST3835, STs belonging to the ST10 complex (ST40, ST167, ST205, ST744 and ST1237), ST88 complex (ST224 and ST410), ST101 complex (ST101) or ST361 complex (ST361) have been found to carry *bla*<sub>NDM-1</sub> in China<sup>4,6–9</sup>. The diversity of clonal background of *E. coli* carrying *bla*<sub>NDM-1</sub> suggests that the dissemination of *bla*<sub>NDM-1</sub> in China was unlikely to be mainly mediated by a particular strain.

In addition to *bla*<sub>NDM-1</sub>, strain WCHEC13-8 had other resistance genes including *bla*<sub>CMY-42</sub> (an extended-spectrum β-lactamase [ESBL] which is globally distributed), *bla*<sub>SHV-12</sub> (an ESBL gene), *bla*<sub>ampC</sub> (a plasmid-borne AmpC cephalosporinase gene), *bla*<sub>CTX-M-14</sub> (a non-ESBL oxacillinase gene), *bla*<sub>arbA</sub> (a chromosome-based AmpC gene), *aac(6’)-Ib-cr* (encoding an aminoglycoside acetyltransferase with low-level activity against fluoroquinolones), *aac(3)-II* (encoding an aminoglycoside acetyltransferase), *mhp* (encoding macrolide 2'-phosphotransferase 1) and *tetB* (confering resistance to tetracycline). Of note, CMY-42, the AmpC enzyme encoded by *bla*<sub>CMY-42</sub>, differs from CMY-2 by a single amino acid substitution, i.e. Ser for Val at Ambler’s position 111<sup>16</sup>. The co-existence of *bla*<sub>NDM-1</sub>, *bla*<sub>CMY-42</sub>, *bla*<sub>CTX-M-15</sub> and *bla*<sub>SHV-12</sub> all of which encode a β-lactamase with the ability to hydrolyse broad-spectrum cephalosporins, in a single isolate has not been reported before. The co-presence of *bla*<sub>NDM-1</sub>, *bla*<sub>CMY-42</sub> and *bla*<sub>CTX-M-15</sub> has been found in an *E. coli* of ST101 from a two-year-old child who had recently travelled to India<sup>11</sup>, while two *E. coli* isolates of ST167 in China have been found carrying *bla*<sub>NDM-1</sub>, *bla*<sub>CMY-42</sub> and *bla*<sub>CTX-M-15</sub><sup>5</sup>. In addition, *bla*<sub>CMY-42</sub> has also been found in two *E. coli* isolates from a river in India (GenBank accession numbers KJ661335 and KJ661336) and one from a surgical wound at a university hospital in Germany<sup>10</sup>, but STs of the three *E. coli* isolates have not been reported. Of note, a report from Egypt also claimed that *bla*<sub>CMY-42</sub> has been detected in 8 *E. coli* isolates<sup>12</sup>, but the gene detected was 99% similar to *bla*<sub>CMY-42</sub> and the amino acid sequence of CMY was not available for analysis. Therefore, it remains unclear whether these Egyptian isolates carried *bla*<sub>CMY-42</sub> or another variant.

Strain WCHEC13-8 had three plasmids, which were approximately 50, 60 and 140 kb in size, as revealed by S1 nuclease pulse-field gel electrophoresis (S1-PFGE). The three plasmids were completely circularised using PCR and Sanger sequencing. *bla*<sub>NDM-1</sub> and *bla*<sub>SHV-12</sub> were carried by a 54-kb plasmid, assigned pNDM1_EC8 here, of the IncX3 group. *bla*<sub>CMY-42</sub> was located on a 64-kb IncI1 plasmid, assigned pCMY42_EC8 here, while *bla*<sub>CTX-M-15</sub> was carried by a 141-kb IncF plasmid, assigned pCTXM15_EC8.<sup>14</sup> pCTXM15_EC8 contained multiple F replicons including one FIA, one FIB and two FII replicons. Based on the replicon sequence typing (RST) for IncF plasmids<sup>13</sup>, the replicon types of pCTXM15_EC8 were F36:A4:B1 (FII 36, FIA 4 and FIB 1) with both FII replicons belonging to the same type. The F36:A4:B1 type has also been seen in plasmid p6409-151.583 kb (GenBank accession number CP010372), which was recovered from an *E. coli* strain in Colombia. However, p6409-151.583 kb has an additional F31 type FII replicon and does not carry *bla*<sub>NDM-1</sub>. Furthermore, the link between pCTXM15_EC8 and p6409-151.583 kb could not be established and the origin of pCTXM15_EC8 remains unknown.

pCMY42_EC8 harboured four of the five loci used for the IncII plasmid MLST scheme<sup>14</sup>. The four loci and their allele numbers were repII (IncII replicon) 4, arda (alleviation of restriction of DNA) 5,
trbA (a gene essential for conjugative transfer) 15 and pilL (a pilus gene) 3. The sogS (suppressor of dnaG mutation) locus was absent from pCMY42_EC8 and therefore no ST could be assigned. Nonetheless, pCMY42_EC8 was closely related to ST55 (repI1-ardA-trbA-sogS-pilL alleles 4-5-15-11-3) and ST141 (4-5-15-4-3). Both STs comprise IncI1 plasmids carrying blaCMY-42 found in Taiwan (pubmlst.org/plasmid).

The genetic context of blaCMY-42 has not been described before. On pCMY42_EC8, blaCMY-42 is adjacent to the insertion sequence ISEcpl, which was truncated by the insertion of IS1, at upstream and a gene encoding outer membrane lipoprotein at downstream (Panel A, Fig. 1). The remaining part of ISEcpl was found 24.7-kb further upstream of blaCMY-42 and was also truncated by IS1. After carefully examining the flanking sequences of ISEcpl and IS1, it became evident that the complex genetic context of blaCMY-42 has been formed by the transposition of ISEcpl and the insertion of two copies of IS1 followed by homologous recombination between the two IS1 (Panel B, Fig. 1) as explained as below. First, both of the two IS1 were flanked by a remnant of ISEcpl and a part of the trbA gene, which is involved in plasmid conjugation. The two remnants of ISEcpl form a complete ISEcpl plus a 9-bp repeat, which abuts the two IS1 and is characteristic of the insertion of IS1. Similarly, the two parts of trbA make the complete trbA plus the characteristic 9-bp repeat. It is therefore clear that both ISEcpl and trbA had been interrupted by the insertion of IS1 and the subsequent homologous recombination between the two copies of IS1 could result in the inversion of the intervening region (Panel B, Fig. 1). Second, it has been proven that a single copy of ISEcpl is able to mobilise its downstream genetic components by using alternative sequences as the right-hand inverted repeat (IRR) 15. By comparing genetic contexts of blaCMY-42 and its variants available in GenBank using BLAST, the same 4 kb element comprising ISEcpl, blaCMY-42 (encoding an outer membrane lipoprotein) and sugE (encoding a quaternary ammonium compound-resistance protein) has been found on different plasmids but with varied abutting sequences. This element is bounded by a 14 bp sequence (AACCGAGAAAGTCGA) at one end, which shows some similarity with the left-hand inverted repeat (IRL) of ISEcpl (Panel B, Fig. 1) and might have served as the alternative IRR (IRR2) for ISEcpl to mobilise blaCMY-42 to different locations. Indeed, when we put the two remnants of ISEcpl back together, we found that the finQ gene (the transcriptional inhibitor of plasmid transfer) has been interrupted by the ISEcpl-blaCMY-42-IIR2 region with the presence of 5-bp direct target repeats (DR), which characterises the insertion of ISEcpl (Panel B, Fig. 1). This confirms that the mobilisation of blaCMY-42 has been mediated by ISEcpl by misidentifying its IRR.

In strain WCHECIC13-8, blaNDM-1 was able to be transferred to E. coli strain J53, suggesting that pNDM1_EC8 was a self-transmissible plasmid. None of the other resistance genes listed above except blasHV12 were co-transferred with blaNDM-1. PCR-based replicon typing (PBRT) failed to assign pNDM1_EC8 to a replicon type as all replicon typing PCR reactions were negative. pNDM1_EC8 was an IncX3 plasmid and IncX3 has not been integrated into the PBRT scheme. pNDM1_EC8 is identical to pNDM-HF727 (GenBank accession number KF976405), an IncX3 plasmid carrying blaNDM-1 from an Enterobacter cloacae strain in China 9.

IncX3 plasmids are narrow-host-range plasmids of Enterobacteriaceae 16. A few IncX3 plasmids carrying ESBL genes (blasHV11 or blasHV14) and/or carbapenemase genes (blasKPC2, blasKPC3, or blasNDM3) from various species of Enterobacteriaceae in several countries have been completely sequenced 17–21. In particular, IncX3 plasmids carrying blasNDM1 and blasHV12 have been identified in various species of the Enterobacteriaceae at multiple locations in China. The completely-sequenced IncX3 plasmids except pKP13d are almost identical in their backbone sequences with less than 9 single nucleotide variations between any two plasmids (Fig. 2). The remarkable similarity between IncX3 plasmids suggests that a common IncX3 plasmid has spread to different continents, acquired the carbapenemase gene that is prevalent locally, e.g. blasKPC2 in USA and blasNDM1 in China, and then were transformed as a vehicle mediating the interspecies spread of carbapenemase genes in local settings.

IncX3 plasmids carrying blasNDM1 and blasHV12 have also been found in strains causing an outbreak in China 22. IncX3 plasmids carrying blasNDM1 and blasHV12 have also been found among the Enterobacteriaceae in the United Arab Emirates (UAE). Of note, one of the UAE strain was recovered two years earlier than the first Chinese strain that harboured an IncX3 plasmid carrying blasNDM1 and blasHV12 was isolated. It remains unclear where the exact origin of emergence of IncX3 plasmids carrying blasNDM1 and blasHV12 is. More studies are warranted to characterise the prevalence of IncX3 plasmids in the Enterobacteriaceae and to understand the emergence and spread of IncX3 plasmids 23.

The genetic context of blasNDM1 on pNDM1_EC8 is identical to those on pNDM-HF727 and several other IncX3 plasmids from China. In such a context, blasNDM1 is adjacent to an IS55-interrupted IS3000-truncated ISAbu125 at upstream and is linked with blasHV12 at downstream (Fig. 3). blasHV12 is flanked by IS26, which could form a composite transposon with the potential to mobilise blasHV12 into different locations.

Conclusions

An ST3835 E. coli clinical isolate carrying multiple genes, e.g. blasNDM1, blasCTX-M-15, blasCMY-42 and blasHV12, which are able to confer resistance to broad-spectrum cephalosporins, was identified in China. Carbapenemase gene blasNDM1 was carried by a self-transmissible IncX3 plasmid in this strain. IncX3 plasmids may have served as a common vehicle mediating the dissemination of blasNDM among the Enterobacteriaceae. The recently-identified plasmid-borne AmpC gene blasCMY-42 was in a complex genetic
Figure 1. Genetic context of bla\textsubscript{CMY-42} and its formation on pCMY42\_EC8. Panel A, The context of bla\textsubscript{CMY-42}. 

\(\Delta\) and shapes with a forked tail represent truncated genes or insertion sequences. The broken line represents a 27.4 kb region between traC and finQ, which is not scaled. The putative alternative IRR (IRR2) of IS\textsubscript{Ecp1} is depicted as a red pole and the alignment of the IRL of IS\textsubscript{Ecp1} and the IRR2 is shown. IS\textsubscript{Ecp1} and traB are both interrupted into two parts. The 9-bp nucleotide repeats belonging to IS\textsubscript{Ecp1} are depicted in blue and those of traB are in red, while the 5-bp nucleotide repeats belonging to finQ is shown in bold. Panel B, The proposed scheme for the formation of the context of bla\textsubscript{CMY-42}. The IS\textsubscript{Ecp1}-bla\textsubscript{CMY-42}-IRR2 region (structure 1) is inserted into the finQ gene of the traA-trbA region (structure 2) on an IncI1 plasmid and then generates the structure 3 with the 5-bp characteristic DR (GATAA). Two copies of IS1 (structure 4) are then inserted into traB and IS\textsubscript{Ecp1}, respectively, generating the structure 5 with the 9-bp DR (CCGTCAATA for traB and CGTTTGAAG for IS\textsubscript{Ecp1}), which is the characteristic of IS1 insertion. The subsequent homologous recombination between the two copies of IS1 mediates the inversion (shown by two broken arrows) of the intervening region (grey part) and then forms the context of bla\textsubscript{CMY-42} on pCMY42\_EC8 (structure 6).
context, which was formed by the transposition of ISEcp1 and the insertion of two copies of IS1 followed by homologous recombination between the two IS1.

Material and Methods

Strain and in vitro susceptibility. Strain WCHEC13-8 was a clinical isolate recovered in West China Hospital of Sichuan University, Chengdu, China. Species identification and in vitro susceptibility test were performed using the Vitek II automated system (bioMerieux, Lyon, France). MICs of imipenem, meropenem, amikacin, ceftazidime and ciprofloxacin were also determined using the microdilution broth method followed recommendations of the Clinical Laboratory Standards Institute.

Detection of carbapenemase-encoding genes. The strain was screened for acquired carbapenemase-encoding genes \(\text{bla}_{\text{GES}}, \text{bla}_{\text{KPC}}, \text{bla}_{\text{IMP}}, \text{bla}_{\text{NDM}}, \text{bla}_{\text{OXA-48}}\) and \(\text{bla}_{\text{VIM}}\) using PCR as described previously. The complete coding sequence of \(\text{bla}_{\text{NDM}}\) was amplified with an additional pair of primers (NDM-up/NDM-dw) and the amplicon was sequenced in both directions using an ABI 3730xl DNA Analyzer (Applied Biosystems, Foster City, CA, USA) at the Beijing Genomics Institute (Beijing, China).
PCR-based replicon typing (PBRT) 34. Sequences of IncX3 plasmids were retrieved from GenBank and strain. Plasmid DNA that was prepared from the transconjugant using alkaline lysis was subjected to confirmed using PCR and ERIC-PCR was used for further distinguishing transconjugants from the donor Spades program29. The Prokka program 30 was employed for annotating the genomic sequence. To identify whether this strain had unique genes, its assembled sequence was compared to the complete chromosome sequences of all of the 83 E. coli strains with their complete genome available in GenBank using the Gegenees program31. Potential unique genes were called using a stringent threshold of a 0.9 or higher score generated by Gegenees and then were confirmed or rejected using the BLAST program (http:// blast.ncbi.nlm.nih.gov) against the 2,159 draft genomes of E. coli (accessed on December 18, 2014) to test whether they were absent from the E. coli draft genome database or not. Function of the products encoded by unique genes was predicted using both the Protein BLAST and InterProScan (http://www. ebi.ac.uk/interpro/) programs. The plasmids carrying blaNDM-1, blaCMY-42 or blaCTX-M-15 were completely circularised in sequence with intervals between contigs being filled by PCR with primers designed based on available sequences and Sanger sequencing.

Strain typing. Phylogenetic group (A, B1, B2 and D) typing was performed as described previously32. Strain WCHEC13-8 was assigned to a ST using the assembled genomic sequence to query the seven alleles of the multi-locus sequence typing scheme for E. coli (http://mlst.warwick.ac.uk/mlst/dbs/Ecoli)33. Clonal complexes were assigned according to the founder ST identified using eBURST.

Mating experiments and plasmid typing. Conjugation experiment was carried out in broth using azide-resistant E. coli strain J53 as the recipient. Transconjugants were selected on plates containing 4 μg/ml meropenem plus 150 μg/ml sodium azide. The presence of blaNDM-1 in transconjugants was confirmed using PCR and ERIC-PCR was used for further distinguishing transconjugants from the donor strain. Plasmid DNA that was prepared from the transconjugant using alkaline lysis was subjected to PCR-based replicon typing (PBRT)34. Sequences of IncX3 plasmids were retrieved from GenBank and aligned using MEGA (version 6). Maximum likelihood phylogenetic tree was constructed using MEGA using backbone sequences. Inc1 plasmid was assigned to ST and the replicon types of the IncF plasmids were assigned after querying their sequence against the plasmid MLST databases (http://pubmlst.org/plasmid/). Plasmids of the same type as pCTXM15_EC8 were identified using concatenated sequence of the IncF replicon alleles of pCTXM15_EC8 for BLAST.

S1-PFGE. S1-PFGE was performed to determine the number and size of plasmids carried by strain WCHEC13-8 as described previously35. Briefly, agarose plugs containing whole-cell DNA of strain WCHEC13-8 were treated with 8 U of S1 nuclease (Fermentas, Thermo Scientific; Waltham, MA, US) and the reaction was stopped by adding 0.5 M EDTA (pH 8). PFGE was conducted with a 1% SeaKem Gold agarose gel (Lonza, Basal, Switzerland) using a CHEF DRII system (Bio-Rad, Hercules, CA, US) at 14°C, with a 6-V/cm current and run times of 12 h at switch time of 5 to 40 s followed by 8 h at switch time of 3 to 8 s. MidRange I PFGE Marker (NEB, Ipswich, MA, US) was used for size estimation.

Nucleotide sequence accession number. Reads and the Whole Genome Shotgun project of WCHEC13-8 genomic sequence have been deposited into DDBJ/EMBL/GenBank under accession SRR2012643 and LCWG00000000, respectively. The sequence of pCMY42_EC8 and pCTXM15_EC8 has been deposited into DDBJ/EMBL/GenBank under accession numbers KP789019 and KP789020, respectively.
