We develop a dynamical approach based on the Schwinger-Keldysh formalism to derive a field-theoretic description of disordered and interacting electron systems. We calculate within this formalism the perturbative RG equations for interacting electrons expanded around a diffusive Fermi liquid fixed point, as obtained originally by Finkelstein using replicas. The major simplifying feature of this approach, as compared to Finkelstein’s is that instead of $N \to 0$ replicas, we only need to consider $N = 2$ species. We compare the dynamical Schwinger-Keldysh approach and the replica methods, and we present a simple and pedagogical RG procedure to obtain Finkelstein’s RG equations.

I. INTRODUCTION

Since the original idea of an impurity driven metal-insulator transition (MIT) was put forward by Anderson \cite{1}, a substantial amount of work has been carried out to understand this problem in the language of phase transitions and of the Renormalization Group (RG) \cite{2,3}. Simple scaling arguments were made for the case of non-interacting electrons. It was demonstrated that there would always be a metal-to-insulator transition in three dimensions as a function of the disorder strength, whereas in one and two dimensions even the weakest amount of disorder would make the system an insulator at zero temperature \cite{3}. The lower critical dimension for the MIT is $d = 2$ for the non-interacting electron problem, and $\epsilon = d - 2$ expansions have been carried out to determine the critical exponents characterizing the phase transition \cite{3}.

These scaling ideas were extended to include the effects of electron-electron interactions by Finkelstein \cite{5}, and later by Castellani et. al. \cite{6}, who obtained RG equations for the conductance, as well as the singlet and triplet interaction coupling constants, starting with a diffusive Fermi liquid fixed point (for a review, see Ref. \cite{7}). This seminal work defined a field theoretical language to study the simultaneous presence of interactions and disorder. Unfortunately, this approach suffered from being inconclusive – since the coupled renormalization group equations flow to strong coupling, away from the perturbative starting point of a diffusive Fermi liquid state – and technically quite involved. A recent discussion of Finkelstein’s replica theory can be found in Ref. \cite{8}.

The recent experimental discovery by Kravchenko and co-workers \cite{9} of a MIT in a two-dimensional Si-MOSFET and the subsequent discovery of such a transition in other two-dimensional electron gas systems has rekindled interest in sharpening our understanding of the combined effects of disorder and interactions. In this paper we will rederive the RG equations for all marginal perturbations of the diffusive Fermi liquid fixed point (there are no relevant perturbations). We will do so using the dynamical Schwinger-Keldysh approach. Our results agree with those obtained using the replica method \cite{5} and disorder-averaged perturbation theory \cite{6}. As we will show, the Schwinger-Keldysh and the replica approaches to studying the diffusive fermi liquid exhibit a very similar structure. It is important to note that, in the replica solution, there are no subtleties involved the $N \to 0$ replica limit at the perturbative level, which reflects the fact that that there is no replica symmetry breaking in the diffusive fermi liquid state. This is the underlying reason why the Schwinger-Keldysh and replica solutions, as we will see, look very much alike, with the dynamical thermal indices for time-ordered and anti-time-ordered fields behaving as simple bookkeeping devices, just as in the replica solution. On the other hand, glassy systems which exhibit replica symmetry breaking, such as the recently proposed Wigner glass phase \cite{13,14} should be rather different and more interesting. We will explore these directions in the future. In the present paper, we will limit ourselves to the study of the diffusive fermi liquid, which we present below.

We present the Schwinger-Keldysh approach for disordered and interacting electronic systems in section \cite{1}, where we show that instead of $N \to 0$ replicas, we only need to consider $N = 2$ species of fields. Using this dynamical approach, we derive in Section \cite{11} a non-linear $\sigma$-model for interacting diffusion modes in the Schwinger-Keldysh
formalism. For simplicity, we restrict attention to the ‘unitary’ case considered in Finkelstein’s original paper [5]: we assume that the electrons interact through a short-range interaction and that they are in a magnetic field which affects their orbital motion, but that the Zeeman coupling vanishes (this situation might be realizable in GaAs-AlGaAs systems). By straightforward extension of the methods used here, we can also treat the more interesting, but more complicated, ‘orthogonal’ case in which the magnetic field is turned off. In a similar vein, we avoid the straightforward but more involved extension to long-range Coulomb interactions. This would include applications of our approach to the quantum Hall plateau transitions. We emphasize the similarities and differences with the replicated $\sigma$-model. In section [IX], we find the diffusive saddle point and bring the $\sigma$-model into a form which is convenient for perturbation theory about this saddle point. This form is used to derive the Feynman rules, given in section [V], which are needed for one-loop perturbative calculations. In section [VI] we use these Feynman rules to discuss the one-loop renormalization of this $\sigma$-model. One of our main purposes here is pedagogy, so we discuss the diagrammatics in detail, paying attention to the symmetry factors and minus signs which prove to be crucial in determining the physics of the model. As we show, the apparent complexity – due to the large number of diagrams – can be offset by a systematic enumeration. Finally, in sections [VII] and [VIII], we discuss the resulting RG equations, a constraint on them following from the Ward identity for charge conservation, and their physics.

II. THE DYNAMICAL SCHWINGER-KELDYSH APPROACH TO DISORDERED AND INTERACTING ELECTRONS

In the Schwinger-Keldysh – or closed time path – formalism [15–17], a functional integral (see also the formulation by Feynman and Vernon, Ref. [18]) is constructed for the time-evolution of the vacuum state from $t = -\infty$ to $t = \infty$ and back to $t = -\infty$ (the Keldysh contour, shown in Fig. 1, is just one possible path for this evolution). Such evolution of the vacuum brings it back to the initial state, and therefore the vacuum-to-vacuum overlap (or vacuum persistence $Z$) in the closed path formalism is 1. Consequently, the functional integral is automatically normalized to $Z = 1$ for any realization of the disorder potential, so disorder-averaged correlation functions can be calculated directly from the disorder-averaged functional integral. The price which must be paid is the doubling of the number of the fields in the theory; the second copy of each field propagates backwards in time.

![Keldysh contour](image)

FIG. 1. Keldysh contour, going from $-\infty$ to $\infty$ and back to $-\infty$.

The application of dynamical approaches, such as the Schwinger-Keldysh formalism, to disordered systems has been previously proposed. At the classical level, Martin, Sigia, and Rose [19] used a dynamical approach and explored the independence of the classical generating functional on the disorder. Sompolinsky [20] used this formalism to study the mean-field theory for the spin glass problem. Quantum versions of the idea of using dynamics to enforce $Z = 1$ have been proposed by Schuster and Vieira [21] and by Kree [22]. However, these proposals were never stated in a language suitable for calculations in disordered systems. A concrete formulation was put forward by Horbach and Schönh [23], who developed a time-path formulation for disordered non-interacting electrons. Recently, Cugliandolo and Lozano [24] proposed a closed time path formalism for quantum spin glasses. In work complementary to ours, Andreev and Kamenev [25] use the Schwinger-Keldysh formalism to address the issue of gauge invariance in disordered interacting electron systems. They discuss the single-particle density of states – which we do not – but do not derive the full set of coupled RG equations – which we do, following Finkelstein.

Here we apply the closed time path formulation, and cast it in a language appropriate to consider the effect of interactions. We give an extended discussion of the method in Ref. [26], where we discuss, in addition to systems with a natural quantum dynamics, a non-trivial extention of the method to systems with no natural quantum or classical dynamics, such as disordered, interacting statistical field theories. Below we give a short summary of the method.

The Keldysh contour in Fig. 1 is just one example of a possible contour for which we can achieve our desired objective, namely the absence of a denominator in the correlation functions (i.e., $Z = 1$). Here we will discuss a more general class of contours originally devised for the study of field theories at finite temperatures [27, 28]. These formulations are carried out in real-time, and their objective was to circumvent pitfalls from the strong assumptions about analytical continuation of imaginary-time (such as Matsubara’s) formulations.
FIG. 2. Real-time separated into four parts that factorize into separate contributions: $C_1 \cup C_2$ and $C_3 \cup C_4$.

At finite temperature, the contour of figure 1 is replaced by a contour running from $t = -\infty$ to $t = \infty$ and thence to $t = -\infty - i\beta$. A contour of this type is displayed in figure 2. For such a contour, there is an important factorization property \[26\], shown in Ref. 29, for the contributions from each piece of the contour to the functional integral $Z$:

$$Z = Z^{C_1 \cup C_2} Z^{C_3 \cup C_4}.\quad (1)$$

Only $C_1$ and $C_2$ are important in obtaining physical correlation functions. \[30\] As a consequence of the factorization property, we can obtain these correlation functions from $Z^{C_1 \cup C_2}$ which satisfies the normalization property:

$$Z^{C_1 \cup C_2} = 1.\quad (2)$$

Hence, even at finite-temperature, we can work with a partition function normalized to 1. Denoting the fields on the upper ($C_1$) and the lower ($C_2$) pieces of the contour by

$$\phi_1(t) = \phi(t), \quad \phi_2(t) = \phi(t - i\sigma), \quad (t = \text{real})\quad (3)$$

eone defines a matrix propagator

$$< T_c[\phi_a(t, x)\phi_b^i(t', x')] = -i\Delta_{ab}(t - t', x - x') \quad (4)$$

where $T_c$ denotes ordering of fields according their position along the contour of Fig. 2. The particular choice $\sigma = \beta/2$ makes the form of the propagators especially simple. Let $\phi$ denote a complex field, bosonic or fermionic. The propagator $i\Delta^{ab}$ can be written in terms of the zero-temperature propagator $i\Delta^{ab}_0$ as

$$i\Delta(\omega, k) = u(\omega) i\Delta_0(\omega, k) u^\dagger(\omega), \quad (5)$$

where

$$i\Delta_0(\omega, k) = \begin{pmatrix} iG_0(\omega, k) & 0 \\ 0 & -iG_0^*(\omega, k) \end{pmatrix}, \quad (6)$$

with $iG_0(\omega, k)$ the usual time-ordered propagator

$$iG_0(t - t', x - x') = \langle T[\phi(t, x)\phi^\dagger(t', x')]\rangle\quad (7)$$

and $-iG_0^*(t - t', x - x')$, consequently, the anti-time-ordered one

$$-iG_0^*(t - t', x - x') = \langle [T[\phi(t, x)\phi^\dagger(t', x')]\rangle^* = \langle [T[\phi(t', x')\phi^\dagger(t, x)]\rangle\quad (8)$$

The matrix $u$ contains the information about the temperature. For bosonic fields, this matrix is given by

$$u(\omega) = u_B(\omega) = \begin{pmatrix} \cosh \Delta\theta_\omega & \sinh \Delta\theta_\omega \\ \sinh \Delta\theta_\omega & \cosh \Delta\theta_\omega \end{pmatrix}, \quad \text{where} \quad \Delta\theta_\omega = \theta_\omega^T - \theta_\omega^T = 0, \quad \text{and} \quad \cosh^2 \theta_\omega^T = \frac{1}{1 - e^{-\omega/T}}.\quad (9)$$

For a fermion field, the matrix is altered to account for the fermionic statistics, and we have

$$u(\omega) = u_F(\omega) = \begin{pmatrix} \cos \Delta\theta_\omega & \sin \Delta\theta_\omega \\ -\sin \theta_\omega & \cos \Delta\theta_\omega \end{pmatrix}, \quad \text{where} \quad \Delta\theta_\omega = \theta_\omega^T - \theta_\omega^T = 0, \quad \text{and} \quad \cos^2 \theta_\omega^T = \frac{1}{1 + e^{-(\omega - \mu)/T}}.\quad (10)$$

Notice that at zero temperature $u_B, F = 1$.

All correlation functions in a theory with propagator $\Delta_{ab}$ and interaction $\mathcal{L}[\phi, \phi^*]$ are obtained using the following functional integral over two fields $\phi_1, \phi_2$:

$$Z = \int D\phi_1 D\phi_2 \exp \left[ i \int \left( \frac{1}{2} \phi_1^* [\Delta^{-1}]^{ab} \phi_b + \mathcal{L}_I[\phi_1, \phi_1^*] - \mathcal{L}_I[\phi_2, \phi_2^*] \right) \right] \quad (11),$$

where all time integrals are to be done from $-\infty$ to $\infty$. This gives rise to a crucial relative sign in how the interaction comes in for the forward propagating field $\phi_1$ and the backward propagating one $\phi_2$.  

III. NON-LINEAR SIGMA MODEL WITHIN THE SCHWINGER-KELDYSH FORMALISM

We start by deriving a non-linear sigma model in the language of the dynamical Schwinger-Keldysh formalism. The steps are quite similar to the derivation in the replica formulation.

As shown above, we formulate the problem in terms of a real time path integral

\[ Z = \int D\psi^\dagger D\psi \ e^{iS[\psi^\dagger,\psi]} \] (12)

for a fermionic field

\[ \psi = \begin{pmatrix} \psi_1 \\ \psi_2 \end{pmatrix} \]

comprised of two components \( \psi_i \) labelled by the thermal indices \( i = 1, 2 \) (in addition to other indices such as spin). The index \( i = 1 \) corresponds to time-ordered fields, and \( i = 2 \) to anti-time-ordered ones.

A. The free action

The free part of the action for these fermions can be written as

\[ S_0[\psi^\dagger,\psi] = \int d^d x \int \frac{d\omega}{2\pi} \ \bar{\psi}(x,\omega) \ u_F(\omega) \ \sigma_3 \ \begin{pmatrix} \omega + \frac{\nabla^2}{2m} + \epsilon_F + i\eta \ \text{sgn}\omega & 0 \\ 0 & \omega + \frac{\nabla^2}{2m} + \epsilon_F - i\eta \ \text{sgn}\omega \end{pmatrix} u_F^\dagger(\omega) \ \psi(x,\omega) , \] (13)

from which we obtain the free matrix propagator

\[ \bar{\psi}\psi^\dagger = i\Delta(\omega, k) = u_F(\omega) \ i\Delta_0(\omega, k) \ u_F^\dagger(\omega) , \] (14)

where

\[ i\Delta_0(\omega, k) = \begin{pmatrix} iG_0(\omega, k) & 0 \\ 0 & -iG_0^*(\omega, k) \end{pmatrix} , \] (15)

and \( iG_0 \) is the time-ordered propagator

\[ iG_0(\omega, k) = \frac{i}{\omega - \frac{\nabla^2}{2m} + \epsilon_F \pm \xi} . \]

Notice that the anti-time-ordered propagator is the adjoint of \( iG_0 \). The matrix \( u_F(\omega) \) containing the temperature dependence was defined above. In particular, \( u_F(\omega) = 1_{\text{thermal}} \) at \( T = 0 \). In this case we have

\[ S_0[\psi^\dagger,\psi] = \int d^d x \int \frac{d\omega}{2\pi} \ \bar{\psi}(x,\omega) \ \begin{pmatrix} \omega + \frac{\nabla^2}{2m} + \epsilon_F + i\eta \ \text{sgn}\omega \\ 1 + i\eta \ \sigma_3 \ \text{sgn}\omega \end{pmatrix} \ \psi(x,\omega) , \] (16)

where in the last line we defined \( \bar{\psi} = \psi^\dagger \sigma_3 \).

B. Disorder term

The static disorder contribution to the action is

\[ S_V[\psi^\dagger,\psi] = \int d^d x \int \frac{d\omega}{2\pi} \ V(x) \ \psi^\dagger(x,\omega) \ \sigma_3 \ \psi(x,\omega) . \] (17)

Notice that any interaction term entering the action has the following properties:

1. It does not mix the two fields \( \psi_{1,2} \). There will be mixing after disorder averaging, but not before.
The disorder potential is assumed to be Gaussian distributed according to

\[ P[V(x)] \propto e^{-\frac{1}{2} \int dx V^2(x)}. \tag{18} \]

We then integrate out the disorder, using the fact that the Schwinger-Keldysh formulation cancels the denominator when we write

\[ Z = \int DQ e^{-\frac{1}{2} \int d^4x \operatorname{tr} Q^2} e^{iS_{HS}[Q,\bar{\psi},\psi]} \tag{21} \]

where

\[ S_{HS}[Q,\bar{\psi},\psi] = i \int d^4x \frac{d\omega}{2\pi} \frac{d\omega'}{2\pi} \bar{\psi}(x,\omega) Q_{\omega\omega'}(x) \psi(x,\omega') . \tag{22} \]

The matrix \( Q \) has indices in three separate spaces, i.e., it is assembled as a direct product in energy, thermal, and spin spaces:

\[ Q^{ij,\alpha\beta}_{\omega\omega'} = \left[ Q^{ij,\alpha\beta}_\omega \right]^* \quad \text{hermitian}. \]

Thus, the trace of \( Q^2 \) corresponds to

\[ \operatorname{tr} Q^2 = \int \frac{d\omega}{2\pi} \frac{d\omega'}{2\pi} \sum_{i,j=1}^{2} \sum_{\alpha,\beta=1}^{2} Q^{ij,\alpha\beta}_{\omega\omega'} Q^{ij,\beta\alpha}_{\omega\omega'} \]

When we write \( Q_{\omega\omega'} \) we mean a matrix whose elements are matrices in thermal \((i, j = 1, 2)\) and spin spaces \((\alpha, \beta = 1, 2)\).

We can then write an expression for \( Z \) as a functional integral over \( \bar{\psi}, \psi \) and \( Q \):

\[ Z = \int DQ \int D\bar{\psi} D\psi e^{-\frac{1}{2} \int d^4x \operatorname{tr} Q^2} e^{iS_0[\bar{\psi},\psi]} e^{iS_{HS}[Q,\bar{\psi},\psi]} \tag{23} \]

where, writing \( S_0 \) and \( S_{HS} \) explicitly in terms of sums over the energy, thermal and spin indices

\[ S_0 + S_{HS} = \int d^4x \frac{d\omega}{2\pi} \frac{d\omega'}{2\pi} \sum_{i,j,\alpha,\beta} \bar{\psi}_{i,\alpha}(x,\omega) \left\{ \left[ \left( \omega + \frac{\eta^2}{2m} + \epsilon_F \right) \delta_{ij} + i\eta \sigma_3^j \text{sgn}\omega \right] \delta_{\alpha\beta} \delta_{\omega\omega'} + iQ^{ij,\alpha\beta}_{\omega\omega'}(x) \right\} \psi_{j,\beta}(x,\omega') . \tag{24} \]

Upon integrating out the fermions we obtain an effective theory for the matrix \( Q \) field,

\[ Z = \int DQ e^{-\frac{1}{2} \int d^4x \operatorname{tr} Q^2} e^{\int d^4x \ln \left[ -\alpha - \eta \left( \frac{\eta^2}{2m} + \epsilon_F \right) \right]} , \tag{25} \]
where we introduced $\Omega$ and $\Lambda$ as matrices in the energy $\otimes$ thermal $\otimes$ spin spaces:

$$\Omega_{\omega,\omega'}^{ij,\alpha\beta} = \omega \delta_{\omega,\omega'} \delta_{ij} \delta_{\alpha\beta}$$ (26)

and

$$\Lambda_{\omega,\omega'}^{ij,\alpha\beta} = \text{sgn} \omega \delta_{\omega,\omega'} \sigma_3^{ij} \delta_{\alpha\beta} \quad \text{or} \quad \Lambda = \sum_3 \otimes \sigma_3 \otimes \mathbb{1}$$ (27)

with $\sum_3$ defined as matrix in energy space that is diagonal and whose entries are $+1$ for positive energies and $-1$ for negative ones.

The expression Eq. (25) is the non-linear sigma model for a non-interacting system. The information necessary to dispose of disconnected loops generated by the disorder average is encoded in the matrix structure for $\Omega$ and $\Lambda$. This structure ensures that we can work with only two indices, $i, j$. Next, we will add the contributions due to interactions.

### C. Interaction term

Let us consider the case of short range interactions, in the singlet and triplet channels:

$$S_{\text{int}} = S_1 + S_2$$

where

$$S_1[\psi^\dagger, \psi] = \pi \Gamma_1 \int d^d \mathbf{x} \int \frac{d\omega}{2\pi} \frac{d\omega'}{2\pi} \sum_{ij,\alpha\beta} \psi_{i,\alpha}^\dagger(x,\omega) \psi_{i,\beta}(x,\omega + \epsilon) \sigma_3^{ij} \psi_{j,\beta}(x,\omega' + \epsilon) \psi_{j,\alpha}(x,\omega')$$ (28)

and

$$S_2[\psi^\dagger, \psi] = -\pi \Gamma_2 \int d^d \mathbf{x} \int \frac{d\omega}{2\pi} \frac{d\omega'}{2\pi} \sum_{ij,\alpha\beta} \psi_{i,\alpha}(x,\omega) \psi_{i,\beta}(x,\omega + \epsilon) \sigma_3^{ij} \psi_{j,\beta}^\dagger(x,\omega' + \epsilon) \psi_{j,\alpha}(x,\omega')$$ (29)

Notice that

1. Once again, the interaction does not mix the fields $\psi$ in different thermal indices $i \neq j$; this is enforced by the $\sigma_3$ matrix in thermal space.

2. The contributions from the two thermal components $i = 1, 2$ enter with opposite signs due to the negative sign for the time integration along the anti-time-ordered branch.

3. Because all four fermions sit on the same index $i$, using the definition $\bar{\psi}_{j,\alpha} = \psi_{i,\alpha}^\dagger \sigma_3^{ij}$ does not change the structure of the interaction as the positive or negative signs from the $\sigma_3$ matrices always come in pairs.

We now introduce two Hubbard-Stratonovich fields $X$ and $Y$ to decouple the four fermion interactions.

$$e^{iS_1[\bar{\psi}, \psi]} = \int D\bar{\psi} \int \psi e^{i\sqrt{2\pi} T \int d^d \mathbf{x} \int \frac{d\omega}{2\pi} \frac{d\omega'}{2\pi} \sum_{ij,\alpha\beta} \bar{\psi}_{i,\alpha}(x,\omega) Y_{\omega,\omega'}^{ij,\alpha\beta}(x) \psi_{j,\beta}(x,\omega')}$$ (30)

$$e^{iS_2[\bar{\psi}, \psi]} = \int DX \int \psi e^{i\sqrt{2\pi} T \int d^d \mathbf{x} \int \frac{d\omega}{2\pi} \frac{d\omega'}{2\pi} \sum_{ij,\alpha\beta} \bar{\psi}_{i,\alpha}(x,\omega) X_{\omega,\omega'}^{ij,\alpha\beta}(x) \psi_{j,\beta}(x,\omega')}$$ (31)

where

$$X_{\omega,\omega'}^{ij,\alpha\beta} = X^{i,\alpha\beta}(\omega - \omega') \delta_{ij} \quad Y_{\omega,\omega'}^{ij,\alpha\beta} = Y^{i}(\omega - \omega') \delta_{\alpha\beta} \delta_{ij}$$
Notice that the matrices $X^{ij,\alpha\beta}$ and $Y_{\omega,\omega'}^{ij,\alpha\beta}$ depend only on the energy difference $\omega - \omega'$. We choose $X$ Hermitian ($X = X^\dagger$), and $Y$ to be anti-Hermitian ($Y = -Y^\dagger$); we could alternatively, have absorbed a factor of $i$ into $Y$ and made it Hermitian. The action for the matrices $i$ is integral and have the at least one of the components is not positive definite is not a problem here because we work with a real time path to generate the correct sign in the four fermion terms for time-ordered and anti-time-ordered pieces. The fact that least one of the components is not positive definite is not a problem here because we work with a real time path integral and have the $i$ factor in front of the actions $S_X$ and $S_Y$ as in Eqs. (30,31).

Including the fields $X$ and $Y$ together with the matrix field $Q$, and integrating out the fermions, we can write the partition function (vacuum persistence) as:

$$Z = \int DX \; DY \; DQ \; e^{\frac{i}{\hbar} \int d^d x \; tr \{ Q^2 \; e^{i S_X[X]} \; e^{i S_Y[Y]} \}}$$

$$= e^{\int d^d x \; \text{ln} \left[ -i \Omega - i \left( \frac{\pi^2}{2} + \epsilon_f \right) \right]} \; 1 + \eta \Lambda + Q(x) - \sqrt{2 \pi T_{12}} \; X(x) - i \sqrt{2 \pi T_{12}} \; Y(x) \right] \right), \quad (34)$$

D. Expansion around the diffusive Fermi liquid fixed point

We will now expand the $\text{tr \ln}$ around the $Q$ saddle of a diffusive Fermi liquid. The saddle point solution for the non-interacting problem is $Q = \pi \nu \nu_0 \, \Lambda$, where $\nu_0$ is the density of states at the fermi level and $\Lambda$ is given in Eq. (27). The matrix $Q$ can be rescaled so that the saddle point can be parametrized as $Q = U^\dagger \Lambda U$. The matrix $Q$ in the non-linear sigma model then satisfy the constraints

$$Q = Q^1, \quad Q^2 = 1, \quad \text{tr} \; Q = 0.$$

The expansion is achieved by allowing a slow position dependence in the matrix $U \rightarrow U(x)$, and considering small couplings $\Gamma_{1,2}$ and small energies $\omega$. Expanding Eq. (34) around the saddle point, we have

$$Z = \int DX \; DY \; DQ \; e^{i S_X[X]} \; e^{i S_Y[Y]}$$

$$e^{\int d^d x \; \left[ D \; \text{tr} \; \left( \nabla Q \right)^2 + 4 \eta \; \text{tr} \; \left[ \left( i \Omega - \eta \Lambda \right) \; Q \right] + 2 \sqrt{2 \pi T_{12}} \; \text{tr} \; \left( X \; Q \right) + 2 i \sqrt{2 \pi T_{12}} \; \text{tr} \; \left( Y \; Q \right) \right]}, \quad (36)$$

where we have also absorbed the rescaling of the saddle into the couplings $\Gamma_{1,2}$, as well as $D$ and $z$. Integrating out $X$ and $Y$, we obtain $Z = \int DQ \; e^{-S[Q]}$, with an effective action for $Q$ as follows:

$$S[Q] = S_D[Q] + S_{\text{tr-}e}[Q]$$

where

$$S_D[Q] = \frac{1}{2} \int d^d x \; \left[ D \; \text{tr} \; \left( \nabla Q \right)^2 + 4 \eta \; \text{tr} \; \left[ \left( i \Omega - \eta \Lambda \right) \; Q \right] \right], \quad (37)$$

$$S_{\text{tr-}e}[Q] = \int d^d x \; \left[ i \pi \Gamma_1 \; Q_{\gamma_1} \; Q_{\gamma_2} - i \pi \Gamma_2 \; Q_{\gamma_1} \right], \quad (38)$$

and the contractions $Q_{\gamma_1} Q$ and $Q_{\gamma_2} Q$ correspond to

$$Q_{\gamma_1} Q = \sum_{i,\alpha,\beta} \int \frac{d\omega_1}{2\pi} \frac{d\omega_2}{2\pi} \frac{d\omega_3}{2\pi} \frac{d\omega_4}{2\pi} \; Q_{i,\omega_1,\omega_2}^{\alpha,\beta} Q_{i,\omega_3,\omega_4}^{\alpha,\beta} \; \sigma_3^{ij} \; 2 \pi \delta(\omega_1 - \omega_2 + \omega_3 - \omega_4), \quad (39)$$

$$Q_{\gamma_2} Q = \sum_{i,\alpha,\beta} \int \frac{d\omega_1}{2\pi} \frac{d\omega_2}{2\pi} \frac{d\omega_3}{2\pi} \frac{d\omega_4}{2\pi} \; Q_{i,\omega_1,\omega_2}^{\alpha,\beta} Q_{i,\omega_3,\omega_4}^{\alpha,\beta} \; \sigma_3^{ij} \; 2 \pi \delta(\omega_1 - \omega_2 + \omega_3 - \omega_4). \quad (40)$$

At this stage we would like to give the expressions for the effective non-linear sigma model Eqs. (37,38). First, notice that the structure is very close to Finkelstein’s replicated model; however, here we have only two “replicas” corresponding to the two thermal indices. Also, the interaction terms $Q_{\gamma_1} Q$ and $Q_{\gamma_2} Q$ do not couple the two thermal spaces much in the same way that the interaction does not couple different replicas. In the Schwinger-Keldysh approach the two thermal indices appear with an opposite sign, hence the $\sigma_3^{ij}$, in contrast to $\delta_{ij}$ as is the case of replicas.
IV. PARAMETRIZATION OF THE SADDLE

We have used above the parametrization $Q = U^\dagger \Lambda U$, where $\Lambda = \Sigma_3^{\text{Energy}} \otimes \sigma_3^{\text{Thermal}} \otimes I^{\text{Spin}}$. The tensor product of the $\Sigma_3$ in energy space and $\sigma_3$ in thermal space makes the parametrization of the saddle rather cumbersome for carrying out calculations. This can be resolved through the use of a transformation that allows us to parametrize around the saddle point

$$\tilde{\Lambda}_{\omega'}^{ij,\alpha\beta} = \text{sgn } \omega \delta_{\omega',\omega} \delta_{ij} \delta_{\alpha\beta} \quad \text{or} \quad \tilde{\Lambda} = \sum_3^{\text{Energy}} \otimes \frac{1}{\text{Thermal}} \otimes \frac{1}{\text{Spin}}.$$  

In this case the thermal and spin structures for the saddle become trivial, and we need only to worry about the energy structure. This transformation is achieved through

$$Q \rightarrow T^\dagger QT$$

where

$$T_{\omega'}^{ij,\alpha\beta} = \begin{cases} \delta_{\omega',\omega} \delta_{ij} \delta_{\alpha\beta} & i = 1 \\ \delta_{\omega,\omega'} \delta_{ij} \delta_{\alpha\beta} & i = 2 \end{cases}$$

The matrix $T$ can be viewed as a direct product of matrices in energy, thermal and spin spaces: $T = U(i) \otimes I_{\text{thermal}} \otimes I_{\text{spin}}$, where $U(i)$ is a rotation in energy space that depends on the thermal index. This transformation leaves the form of the action invariant, with the exception of $\Lambda \rightarrow \tilde{\Lambda}$ and $\Omega \rightarrow \tilde{\Omega}$, where

$$\tilde{\Omega}_{\omega'}^{ij,\alpha\beta} = \omega \delta_{\omega',\omega} \sigma_3^{ij} \delta_{\alpha\beta}.$$  

It is easy to check that the forms of $Q\gamma_1 Q$ and $Q\gamma_2 Q$ remain unchanged upon using the transformation $T$ (the interaction does not mix thermal indices, so for $i = 1$ this is trivial, and for $i = 2$ one can absorb all changes in sign by redefining the integration variables).

The parameterization of $Q$ around the $\tilde{\Lambda}$ saddle becomes simple and familiar, as in the work of Hikami [31]:

$$\omega' > 0 \quad \omega' < 0$$

$$Q = \begin{bmatrix} \sqrt{1 - V^\dagger V} & V^\dagger \\ V & -\sqrt{1 - VV^\dagger} \end{bmatrix} \begin{bmatrix} \omega > 0 \\ \omega < 0 \end{bmatrix} \quad (41)$$

where the matrix $V_{\omega'}$ has row indices with negative energies ($\omega < 0$) and column indices with positive energies ($\omega' > 0$). As in several other works (see, for example, the work by McKane and Stone [32], and by Grilli and Sorella [33]), we will proceed with the study of the nonlinear sigma model by expanding in powers of the $V, V^\dagger$ matrices:

$$Q = \sum_n Q^{(n)}$$

where $n$ is the order in the power series expansion in $V, V^\dagger$. For example,

$$Q^{(0)} = \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix}, \quad Q^{(1)} = \begin{bmatrix} 0 & V^\dagger \\ V & 0 \end{bmatrix}, \quad Q^{(2)} = \begin{bmatrix} -\frac{1}{2}V^\dagger V & 0 \\ 0 & \frac{1}{2}VV^\dagger \end{bmatrix}$$

$$Q^{(3)} = 0, \quad Q^{(4)} = \begin{bmatrix} -\frac{1}{8}(V^\dagger V)^2 & 0 \\ 0 & \frac{1}{8}(VV^\dagger)^2 \end{bmatrix}, \quad \ldots$$

The quadratic piece of the expansion of the action $S_D[Q]$ in powers of $V, V^\dagger$ is

$$S_D^{(2)}[Q] = \frac{1}{2} \int d^4x \left[D \text{ tr } (\nabla Q^{(1)})^2 + 4z \text{ tr } [(i\tilde{\Omega} - \eta \tilde{\Lambda}) Q^{(2)}] \right]$$

$$= \frac{1}{2} \int d^4x \int \frac{d\omega}{2\pi} \int \frac{d\omega'}{2\pi} \sum_{ij,\alpha\beta} \left[D \nabla Q^{(1)}_{ij,\alpha\beta} \nabla Q^{(1)}_{ij,\alpha\beta} + 4z (i\tilde{\Omega}^{ij,\alpha\beta} - \eta \tilde{\Lambda}_{ij,\alpha\beta}) Q^{(2)}_{ij,\alpha\beta} \right]$$

$$= \int d^4k \int_{\omega > 0} \frac{d\omega}{2\pi} \int_{\omega' < 0} \frac{d\omega'}{2\pi} \sum_{ij,\alpha\beta} \left[Dk^2 - iz (\omega \sigma_3^{ij} - \omega' \sigma_3^{ji}) \right] V^{ij,\alpha\beta}_{\omega'}(k) V^{ji,\beta\alpha}_{\omega'}(-k)$$
and
\[ S^{(2)}_{\text{e-e}}[Q] = \int d^d x \left[ i\pi \Gamma_1 Q^{(1)} \gamma_1 Q^{(1)} - i\pi \Gamma_2 Q^{(1)} \gamma_2 Q^{(1)} \right] \] (45)
with
\[ Q^{(1)} \gamma_1 Q^{(1)} = \sum_{i,\alpha\beta} \int \frac{d\omega_1}{2\pi} \frac{d\omega_2}{2\pi} \frac{d\omega_3}{2\pi} \frac{d\omega_4}{2\pi} Q^{(1)i\alpha\alpha} Q^{(1)i\beta\beta} \omega_{1\omega_2} \omega_{3\omega_4} \sigma_3^{i\beta} 2\pi \delta(\omega_1 - \omega_2 + \omega_3 - \omega_4) \] (46)
\[ = 2 \sum_{i,\alpha\beta} \int \frac{d\omega_1}{2\pi} \frac{d\omega_1}{2\pi} \int \frac{d\omega_2}{2\pi} \frac{d\omega_3}{2\pi} V^{i\alpha\alpha} V^{i\beta\beta} \omega_{1\omega_2} \omega_{3\omega_4} \sigma_3^{i\beta} 2\pi \delta(\omega_1 - \omega_2 + \omega_3 - \omega_4) \] (47)
\[ Q^{(1)} \gamma_2 Q^{(1)} = \sum_{i,\alpha\beta} \int \frac{d\omega_1}{2\pi} \frac{d\omega_2}{2\pi} \frac{d\omega_3}{2\pi} \frac{d\omega_4}{2\pi} Q^{(1)i\alpha\beta} Q^{(1)i\alpha\beta} \omega_{1\omega_2} \omega_{1\omega_4} \sigma_3^{i\beta} 2\pi \delta(\omega_1 - \omega_2 + \omega_3 - \omega_4) \] (48)
\[ = 2 \sum_{i,\alpha\beta} \int \frac{d\omega_1}{2\pi} \frac{d\omega_2}{2\pi} \int \frac{d\omega_2}{2\pi} \frac{d\omega_3}{2\pi} V^{i\alpha\beta} V^{i\alpha\beta} \omega_{1\omega_2} \omega_{3\omega_4} \sigma_3^{i\beta} 2\pi \delta(\omega_1 - \omega_2 + \omega_3 - \omega_4) \] (49)

Notice that the contribution to quadratic order coming from \( Q^{(2)} \gamma Q^{(0)} \) vanishes due to the trace, as do contributions to any order in the expansion of \( Q \gamma Q \) where \( Q^{(0)} \) appears as one of the two \( Q \) terms.

**V. FEYNMAN RULES**

We now present the Feynman rules which follow from the action \( S_D + S_{\text{e-e}} \). Our theory is parametrized most succinctly in terms of the \( V \) matrix used above. The basic propagator is the \( (VV) \) propagator or diffusion propagator which follows from \( S_D \). It is represented by a thick line, as in figure 3(a), but it can be understood as a double-line comprised of an electron and a hole. It carries momentum \( q \) and the two frequencies, \( \epsilon, \epsilon + \omega \) of the electron and hole. The arrow is in the direction of the larger frequency. The propagator also carries two thermal indices and two spin indices (one each for the electron and the hole). The action \( S_D + S_{\text{e-e}} \) contains terms of all orders in \( V \). However, not all of these are needed at the one-loop level, as we now show.

Let us start by counting which vertices we need to include in the renormalization program. We can determine the loop order of any diagram \( 3 \) by considering the number \( n_v \) of vertices with \( v \) legs, and the number of external lines \( E \). The number of legs in all vertices must equal the number of external legs plus twice the number of internal lines (each internal line belongs to two vertices):
\[ E + 2I = \sum_v v n_v . \] (50)
The loop order is the net number of momentum integrals, which is the number of internal lines minus the number of contraints from momentum conservation in each vertex, plus an overall momentum conservation constraint
\[ L = I - \sum_v n_v + 1 . \] (51)
Thus,
\[ L = \sum_v n_v \left( \frac{1}{2} v - 1 \right) - \frac{1}{2} E + 1 . \] (52)

With these relations in hand, it is simple to check that we only need to consider three and four point vertices in the one-loop \( (L = 1) \) renormalization of the sigma model. As mentioned above, the RG flows can be obtained from the two-point function alone, so we set \( E = 2 \). Thus, we have
\[ 1 = \sum_v n_v \left( \frac{1}{2} v - 1 \right) \] (53)
which has only two solutions: \( (v = 3, n_v = 2) \) or \( (v = 4, n_v = 1) \).
Hence, at the one-loop level, we need only consider the two-point vertex which follows from the expansion of $S_{e-e}$ to quadratic order in the $V$ matrix; the triangle vertices which follow from its expansion to third order in $V$; and the square vertices which follow from its expansion to fourth order as well as the expansion of $S_D$ to fourth order. The index structure of the former follows from (46). The index structure of the latter two follow from the fact that the thick lines are understood as splitting at the vertices to give the thin lines of the vertices; frequencies, spin, and thermal indices from the thick lines then split and follow the thin lines, as we demonstrate with the spin indices in figure 3(c). At the interaction ‘dots’, they follow the same rules as at the two-point vertices. In figure 3(b), there is a matrix structure $\delta^{\alpha\gamma} \delta^{\beta\mu}$ if the interaction ‘dot’ is a $\Gamma_1$ and $\delta^{\alpha\mu} \delta^{\beta\nu}$ if the interaction ‘dot’ is a $\Gamma_2$. This is abbreviated as $\Gamma$. The frequencies have an overall $\delta$-function at the ‘dot’. The Feynman rules are summarized below.

**Propagator and Diffusion Vertex.** At the one-loop level, we need only consider the first two terms in the expansion of $S_D$. They are the propagator and the diffusion vertex. The propagator is given by:

$$ (a) = \langle V_{ij,\alpha\beta}^{+}(q) V_{k\mu,\nu}(q) \rangle = \frac{1}{-i z} \left( \omega_{\alpha} \sigma_{\beta 3}^{ii} - \omega_{\beta} \sigma_{\alpha 3}^{ij} \right) + D q^2 \delta^{ij} \delta^{jk} \delta^{\alpha\mu} \delta^{\beta\nu} 2 \pi \delta \left( \omega_1 - \omega_2 - \omega_3 + \omega_4 \right) $$

(54)

The second term in the expansion of $S_D$ is the box, (e). It is given by:

$$ (e) = \frac{D}{8} \left[ 2 \left( q_1 \cdot q_3 + q_2 \cdot q_4 \right) + \left( q_1 + q_3 \right) \cdot \left( q_2 + q_4 \right) \right] + \frac{i}{16} \left[ \omega_1 \sigma_{\alpha 3}^{ii} - \omega_2 \sigma_{\beta 3}^{ij} + \text{perm.} \right]. $$

(55)

We have omitted in the expression above the momentum and frequency conserving delta functions. The $q_i$’s are the momenta on the four external legs. These legs can have arrows alternating between in and out as one goes around the box, with two pointing in and two pointing out.

**Interaction Vertices.** The two-point vertex results from the lowest order term in the expansion of $S_{e-e}$:

$$ (b) = 2 \pi i \left( -\Gamma_1 \delta^{\alpha\beta} \delta^{\mu\nu} + \Gamma_2 \delta^{\alpha\nu} \delta^{\beta\mu} \right) \sigma_{\beta 3}^{ii} 4 \pi \delta \left( \omega_1 - \omega_2 + \omega_3 - \omega_4 \right) $$

(56)

The next terms in the expansion of the interaction are the triangle terms:

$$ (c), (d) = \mp i \pi \Gamma $$

(57)

where $\Gamma$ can be either $\Gamma_1$ or $\Gamma_2$ (the suppressed index structure is an extension of the two-point case, as we discussed above) and the arrowless propagator can have an arrow pointing in either direction.

Diagrams (f) (and a similar one with the arrows reversed) and (g) are the quartic terms resulting from the expansion of the interaction.

FIG. 3. The propagator and two-, three-, and four-point vertices.
(f) = \frac{-i\pi}{4} \Gamma \quad (g) = \frac{+i\pi}{2} \Gamma

Decoration of the Interaction Vertices. At the one-loop level, we do not need to consider terms of higher order than the above. However, there can still be terms of arbitrarily high order in \(\Gamma\) because there are quadratic interaction terms. These can be obtained by grouping all of the quadratic terms together and inverting them to obtain the full propagator:

\[
\langle V^{ij,\alpha\beta}_{\omega_1\omega_2}(q) V^{kl,\mu\nu}_{\omega_3\omega_4}(-q) \rangle = D_0 \delta^{ij} \delta^{\alpha\beta} \delta^{\mu\nu} 2\pi \delta (\omega_1 - \omega_2) 2\pi \delta (\omega_2 - \omega_3) - 2\pi i \Gamma_1 D_1 D_2 \delta^{ij} \delta^{\ell k} \delta^{\alpha\beta} \delta^{\mu\nu} 2\pi \delta (\omega_1 - \omega_2 + \omega_3 - \omega_4) + 2\pi i \Gamma_2 D_2 \delta^{ij} \delta^{\ell k} \delta^{\alpha\beta} \delta^{\mu\nu} 2\pi \delta (\omega_1 - \omega_2 + \omega_3 - \omega_4) (58)
\]

Note that the interaction terms are distinguished from the propagator by the \(\delta^{ij}\) on the thermal indices and the overall energy function. Here, \(z_1 = z - 2\Gamma_1 + \Gamma_2 \equiv z - 2\Gamma_s\), and \(z_2 = z + \Gamma_2 \equiv z - 2\Gamma_t\), where we have introduced the singlet and triplet interaction amplitudes, \(\Gamma_s = \Gamma_1 - \Gamma_2/2\), \(\Gamma_t = -\Gamma_2/2\) by rewriting:

\[
\Gamma_1 \delta^{\alpha\beta} \delta^{\mu\nu} - \Gamma_2 \delta^{\alpha\nu} \delta^{\beta\mu} = \left( \Gamma_1 - \frac{1}{2} \Gamma_2 \right) \delta^{\alpha\beta} \delta^{\mu\nu} - \frac{1}{2} \Gamma_2 \sigma^{\alpha\beta} \cdot \sigma^{\mu\nu} (60)
\]

The inversion is more simply done in the singlet-triplet decomposition since these matrices are orthogonal. It can then be re-expressed in the form \((59)\) where \(D_0, D_1, D_2\) are given by:

\[
D_0 = \frac{1}{-iz \left( \omega_1 \sigma_3^{ij} - \omega_2 \sigma_3^{kl} \right) + Dq^2}
\]

\[
D_1 = \frac{1}{-iz_1 \left( \omega_1 \sigma_3^{ij} - \omega_2 \sigma_3^{kl} \right) + Dq^2}
\]

\[
D_2 = \frac{1}{-iz_2 \left( \omega_1 \sigma_3^{ij} - \omega_2 \sigma_3^{kl} \right) + Dq^2}
\]

Hence, by inverting the sum of all of the quadratic terms (rather than just the quadratic term coming from \(S_D\)) and amputating the propagators entering and leaving the vertex, we effect the replacement

\[
(b) = 2\pi i \left( -\Gamma_1 \frac{D_1 D_2}{D_0^2} \delta^{\alpha\beta} \delta^{\mu\nu} + \Gamma_2 \frac{D_2}{D_0} \delta^{\alpha\nu} \delta^{\beta\mu} \right) \sigma_3^{ii} 2\pi \delta (\omega_1 - \omega_2 + \omega_3 - \omega_4) (62)
\]

This can, equivalently, be obtained by summing the geometric series of figure \((a)\). It is this peculiar property of this theory – namely that there are quadratic interactions – which lead to one-loop RG equations which have terms of all orders in \(\Gamma_2\).

FIG. 4. The geometric series of diagrams which decorate the two-, three-, and four-point vertices.
Similarly, when the interaction in (c), (d), (f), or (g) is on an internal line, we can sum the infinite series of figure (b) or (c) and, again, make the replacement

\[ \Gamma_1 \rightarrow \Gamma_1 \frac{D_1 D_2}{D_0^2} \]
\[ \Gamma_2 \rightarrow \Gamma_2 \frac{D_2}{D_0} \]  

While the decoration of vertices leads to a replacement of propagators, the decoration of propagators themselves – and, in particular, external legs – is superfluous since the first term in (59), which has the desired index structure, is not affected by decoration. The decoration of an external line of a vertex amounts to propagator decoration and is similarly ignored.

VI. RENORMALIZATION OF THE $\sigma$-MODEL

There are four couplings, $D$, $z$, $\Gamma_{1,2}$, in our action,

\[ S = \frac{1}{2} \int d^2x \left[ D \text{tr} (\nabla Q^{(1)})^2 + \text{tr} \left[ (4iz\hat{\Omega} - \eta\hat{\Lambda}) Q^{(2)} \right] \right] + \int d^2x \left[ i\pi \Gamma_1 Q^{(1)} \gamma_1 Q^{(1)} - i\pi \Gamma_2 Q^{(1)} \gamma_2 Q^{(1)} \right] \]  

All of these couplings are present in the quadratic terms in the action. Hence, the RG flows can be computed from the two-point function alone, separating the different contributions according to their spin, frequency, and Schwinger-Keldysh matrix structures.

First, there is the diffusion constant, $D$ – or, equivalently, the resistivity, $g = 1/(2\pi)^2 D$). In the non-interacting $\sigma$-model, this is the only coupling constant. In the interacting case, it is still used as the expansion parameter: we assume that $g$ is small, but make no assumptions about $\Gamma_{1,2}$. The second coupling constant is $z$, the relative rescaling of time versus space. $g$ and $z$ are renormalized by the diagrams of figure 5. The other couplings are the interactions $\Gamma_{1,2}$, which are renormalized by the diagrams of figures 6-13. Contributions to the $Q$ self-energy determine the flow of $D$ or $z$ if they are proportional to $q^2$ or $\omega$, respectively, provided they have the correct thermal index structure. They determine the flow of $\Gamma_{1,2}$ if they are independent of the external and frequency and are diagonal in the thermal indices; they contribute to one or the other depending on their spin structure.

It is a matter of taste whether or not we choose to introduce a ‘wavefunction’ renormalization $\zeta$, since this can be completely absorbed in the renormalization of $D$ and $z$. There is a natural definition of $\zeta$ which is related to the density of states, but this is moot for the scaling equations which we consider because we can rescale our couplings to eliminate $\zeta$. Hence, we sweep the wavefunction renormalization under the rug in this paper.

At tree-level, $D$, $z$, $\Gamma_{1,2}$, are marginal. (One might have expected $\Gamma_{1,2}$ to have the dimensions of (length)$^{-2}$, but they do not as a result of the extra frequency integral.) To find the fluctuation corrections to their scaling behavior, we use a Wilsonian shell elimination scheme in which we compute their change as we integrate out shells

\[ \Lambda - d\Lambda < Dq^2 < \Lambda, \quad 0 < \omega < \Lambda \]
\[ \Lambda - d\Lambda < \omega < \Lambda, \quad 0 < Dq^2 < \Lambda \]  

\[ 1 \]the quotation marks refer to the fact that we mean a renormalization of $V$, not $\psi$
Renormalization of \( D \) and \( z \). Let us examine figure 5. By inspection, we see that these diagrams have the appropriate matrix structure for the propagator, i.e. the matrix structure of (54). Diagrams without an interaction vertex do not contribute to the renormalization of \( D \) to one-loop order; the reason is that there is a cancellation between the two (time-ordered and anti-time-ordered) Schwinger-Keldysh species. In the case of the replica calculation, the contribution to one-loop order is proportional to the replica number \( N \rightarrow 0 \).

The diagrams in figure 5 give the following contribution to the \( Q \)-field self-energy, \( \Sigma \):

\[
\Sigma(q, \Omega + \epsilon, \epsilon) = \Sigma_A(q, \Omega + \epsilon, \epsilon) + \Sigma_B(q, \Omega + \epsilon, \epsilon),
\]

(66)

where

\[
\Sigma_A(q, \Omega + \epsilon, \epsilon) = -4 \int \frac{d^2k}{(2\pi)^2} \frac{d\omega}{2\pi} (-2\pi i) \left[ \Gamma_1(k, \omega) - 2\Gamma_2(k, \omega) \right] D_0^2(k, \omega) \left[ \frac{D}{8} (k + q)^2 - i \frac{\omega}{8} (k + \Omega) \right]
\]

(67)

is the contribution of the diagram on the left and

\[
\Sigma_B(q, \Omega + \epsilon, \epsilon) = 4 \int \frac{d^2k}{(2\pi)^2} \frac{d\omega}{2\pi} (-\frac{\pi i}{4}) \left[ \Gamma_1(k - q, \omega - \Omega) - 2\Gamma_2(k - q, \omega - \Omega) \right] D_0(k, \omega)
\]

(68)

is the contribution of the diagram on the right. There is a relative factor of 2 between the \( \Gamma_1 \) and \( \Gamma_2 \) contributions because the former contribution has no free internal spin indices while the latter has one which is summed over. Notice that \( \Sigma_A \) and \( \Sigma_B \) cancel at \( q = \Omega = 0 \). The contribution of \( \Sigma_A \) as well as a piece of \( \Sigma_B \) are absorbed into the wavefunction renormalization. Differentiating with respect to \( \omega \) or \( q^2 \), respectively, we get, to lowest-order in \( \Gamma_1, \Gamma_2 \), the one-loop contributions to \( dD \) and \( dz \) (the external frequencies and momenta have been set to zero after differentiation):

\[
dD = -\left( \frac{d\Sigma_B}{dq^2} \right)_{q=0,\Omega=0} = -D (-2\pi i) \int \frac{d^2k}{(2\pi)^2} \frac{d\omega}{2\pi} \left[ \Gamma_1(k, \omega) - 2\Gamma_2(k, \omega) \right] D_0^3(k, \omega) Dk^2
\]

(70)

\[
dz = -i \left( \frac{d\Sigma_B}{d\Omega} \right)_{q=0,\Omega=0} = -\frac{1}{2} \int \frac{d^2k}{(2\pi)^2} \left[ \Gamma_1(k, 0) - 2\Gamma_2(k, 0) \right] D_0(k, 0)
\]

(71)

In the \( dz \) term, the \( \Omega \) derivative cancels the \( \omega \) integral.

Making the replacement (63), we get:

\footnote{The \( \Sigma_B \) contribution includes a term of the form:

\[
4 \Gamma_2 \int \frac{d^2k}{(2\pi)^2} \frac{d\omega}{2\pi} D_0(k, \omega) Dz(k, \omega)
\]

which comes from differentiating \( D_0 \) with respect to \( q^2 \). The wavefunction renormalization multiplies the \( V \) fields and therefore resurfaces in the renormalization of \( \Gamma_2 \).}

FIG. 5. The self-energy diagrams which renormalize \( z \) and \( D \).
\[- \frac{dD}{D} = (-2\pi i) \int \frac{d^2k}{(2\pi)^2} \frac{d\omega}{2\pi} Dk^2 \left[ \Gamma_1 D_0(k,\omega) D_1(k,\omega) D_2(k,\omega) - 2 \Gamma_2 D_0^2(k,\omega) D_2(k,\omega) \right] \tag{72} \]

dz = -\frac{1}{2} (\Gamma_1 - 2\Gamma_2) \int \frac{d^2k}{(2\pi)^2} D_0(k,0) \tag{73} \]

The contribution to \(dz\) is unchanged but the contribution to \(dD\) receives corrections of all order in \(\Gamma_{1,2}\). This result is the full one-loop result: it is lowest order in \(g\) but to all orders in \(\Gamma_{1,2}\).

The integrals (70) and (72) are discussed in the appendix. Here, we just state the result:

\[
\frac{dg}{dl} = g^2 (\Gamma_1 f_2 (z,z_1,z_2) - 2\Gamma_2 f_2 (z,z,z_2))
\]

\[
\frac{dz}{dl} = g (-\Gamma_1 + 2\Gamma_2) \tag{74} \]

where \(dl = -d(\ln \Lambda)\) and we have made the substitution \(g = \frac{1}{8\pi D} \frac{1}{35}\). Following Finkelstein, we have introduced the functions:

\[
f_1 (z,z_2) = \frac{1}{z_2 - z} \ln \left( \frac{z_2}{z} \right)
\]

\[
f_2 (z,z_1,z_2) = \frac{2z_1}{z_1 - z_2} f_1 (z,z_1) - \frac{2z_2}{z_1 - z_2} f_1 (z,z_2) \tag{75} \]

As we show in the appendix, the functions \(f_{1,2}\) arise as a result of the mismatch between the poles of the propagators \(D_{0,1,2}\). In the non-interacting case, in which these propagators are equal, these functions are just constants, \(f_1 (z,z) = 1, f_2 (z,z,z) = 2\). Interactions split the energies of singlet and triplet particle-hole states from their non-interacting value, leading to (75).

**Renormalization of \(\Gamma_{1,2}\).** The diagrams which renormalize \(\Gamma_1\) are in figures 6 and 8-10 while the related diagrams which renormalize \(\Gamma_2\) are in figures 6 and 8-10. In 8-13, we have, for the sake of completeness and pedagogy, enumerated all of the diagrams which contribute to the renormalization of \(\Gamma_{1,2}\). On combinatoric grounds, we see that we have included all 20 of the diagrams which contribute to \(\Gamma_1\) and the 20 which contribute to \(\Gamma_2\). All of these diagrams must be taken into account to obtain the correct signs and relative coefficients of various terms in the RG equations. However, these two sets of 20 are really elaborations of two sets of 5 diagrams. In figure 6, we give the 5 basic diagrams for \(\Gamma_1\); figures 8-13 are put in an appendix to avoid unnecessary clutter and confusion. From diagram 6(a) we obtain the 6 diagrams of 8(a). From each of 6(b), 6(c), and 6(d), we obtain 4 diagrams shown, respectively, in figure 8(b), 9(c), and 9(d). Finally, figure 6(e) gives rise to the two diagrams of figure 10.

In figure 6, \(\Gamma_1\) contributes to the renormalization of \(\Gamma_2\) and vice versa. When only \(\Gamma_2\)’s appear in diagrams 8-13, the spin index structures dictate that 8-10 contribute to the flow of \(\Gamma_1\) while 11-13 contribute to the flow of \(\Gamma_2\). If any of the vertices are \(\Gamma_1\)’s, however, corresponding diagrams in 8-10 and 11-13 cancel. Hence, we need only consider \(\Gamma_2\)’s in diagrams 9-13.

**FIG. 6.** The lowest order diagram which renormalizes \(\Gamma_{1,2}\).
FIG. 7. The five ‘primitive’ diagrams which renormalize $\Gamma_1$. They are elaborated in figures 8-10. The corresponding elaboration for $\Gamma_2$ is in figures 11-13.

Corresponding diagrams of figures 8-10 and 11-13 give identical contributions, apart from a factor of 2 coming from a spin sum, so we will focus on 8-10. Figure 8(a) gives a contribution

$$-2\pi i d\Gamma_1 = (i\pi \Gamma_2)^2 \int \frac{d^2 k}{(2\pi)^2} \frac{d\omega}{2\pi} D_0^2(k;\omega)$$  \hspace{1cm} (77)$$

The signs of the six diagrams ((iii) and (iv) are two diagrams each because the arrow can point in either direction on the arrowless lines) are determined by the relative signs of the two triangle vertices (57). The first two diagrams come with a positive sign while the other four come with a negative sign. Adding these together, we obtain the coefficient $-2$. Both of the interaction ‘dots’ are on internal lines, so we make the replacement (63):

$$-2\pi i d\Gamma_1^{(a)} = -2 (i\pi \Gamma_2)^2 \int \frac{d^2 k}{(2\pi)^2} \frac{d\omega}{2\pi} D_0^2(k;\omega)$$ \hspace{1cm} (78)$$

In figure 8(b), there are four diagrams and they all come with positive signs. Only one interaction ‘dot’ is on an internal line, so we have:

$$-2\pi i d\Gamma_1^{(b)} = 4 (i\pi \Gamma_2)^2 \int \frac{d^2 k}{(2\pi)^2} \frac{d\omega}{2\pi} D_0(k;\omega)D_2(k;\omega)$$ \hspace{1cm} (79)$$

The diagrams of figure 11(b) vanish because the integrated frequency is overdetermined. However, the wavefunction renormalization coming from the neglected part of $\Sigma_B$ makes up the missing contribution.

In figure 9(c), the four diagrams have positive signs. There are three interactions, but one is on an external line, so there’s a contribution:

$$-2\pi i d\Gamma_1^{(c)} = 4 (i\pi \Gamma_2)^2 (i2\pi \Gamma_2) \int \frac{d^2 k}{(2\pi)^2} \frac{d\omega_1}{2\pi} \int_0^\Lambda \frac{d\omega_2}{2\pi} \frac{D_0(k,\omega_1 - \omega_2)[D_2(k,\omega_1 - \omega_2)]^2}{2\pi}$$

$$= 4 (i\pi \Gamma_2)^2 (i2\pi \Gamma_2) \int \frac{d^2 k}{(2\pi)^2} \frac{d\omega}{2\pi} \frac{\omega}{2\pi} D_0(k,\omega)[D_2(k,\omega)]^2 ,$$  \hspace{1cm} (80)$$

where we have set $\omega = \omega_1 - \omega_2$ as the only variable inside the propagators, and obtained the phase space factor $\frac{\omega}{2\pi}$ from integrating the intermediate frequencies.

Figure 9(d), on the other hand, comes with a negative sign and only one internal interaction:

$$-2\pi i d\Gamma_1^{(d)} = -4 (i\pi \Gamma_2)^2 (i2\pi \Gamma_2) \int \frac{d^2 k}{(2\pi)^2} \frac{d\omega}{2\pi} \frac{\omega}{2\pi} [D_0(k,\omega)]^2 D_2(k,\omega)$$ \hspace{1cm} (81)$$

The coefficient 4 is important for the physics of this theory. In Finkelstein’s original paper [5], the contributions from the diagrams of figure 9 were too small by a factor of 2. As a result, a metallic fixed point with infinite conductivity was found. This error was corrected in [36,37].

Finally, we have the two figures 10(e)
\[ -2\pi i \frac{d\Gamma_1^{(e)}}{d\Gamma_1} = -2 (i\pi \Gamma_2)^2 \left(\frac{2\pi \Gamma_2}{2\pi}\right)^2 \int \frac{d^2k}{(2\pi)^2} \frac{d\omega}{2\pi} \left(\frac{\omega}{2\pi}\right)^2 [D_0(k,\omega)]^2 [D_2(k,\omega)]^2, \tag{82} \]

where, as in cases (c) and (d), there are intermediate frequency integrals that lead to the phase space factor \(\left(\frac{\omega}{2\pi}\right)^2\).

The integrals in the expressions above are discussed in the appendix. Their upshot is:

\[
\begin{align*}
\frac{d\Gamma_1^{(a)}}{d\Gamma_1} &= -\frac{\Gamma_2^2}{z_2} g d \ln(\Lambda) \\
\frac{d\Gamma_1^{(b)}}{d\Gamma_1} &= 2\Gamma_2 f_1(z, z_2) g d \ln(\Lambda) \\
\frac{d\Gamma_1^{(c)}}{d\Gamma_1} &= -\frac{\Gamma_2^2}{z_2} f_2(z, z, z_2) g d \ln(\Lambda) \\
\frac{d\Gamma_1^{(d)}}{d\Gamma_1} &= \frac{\Gamma_2^2}{z} f_2(z_2, z_2, z) g d \ln(\Lambda) \\
\frac{d\Gamma_1^{(e)}}{d\Gamma_1} &= -\frac{1}{2} \frac{1 + 1/2 - 2f_1(z, z_2)}{(z - z_2)^2} g d \ln(\Lambda) 
\end{align*} \tag{83} \]

Adding these contributions, we obtain:

\[
\frac{d\Gamma_1^{(a)}}{d\Gamma_1} + \frac{d\Gamma_1^{(b)}}{d\Gamma_1} + \frac{d\Gamma_1^{(c)}}{d\Gamma_1} + \frac{d\Gamma_1^{(d)}}{d\Gamma_1} + \frac{d\Gamma_1^{(e)}}{d\Gamma_1} \equiv -\Phi = \frac{\Gamma_2^2}{z} g d \ln(\Lambda) \tag{84} \]

**VII. RENORMALIZATION GROUP EQUATIONS**

Gathering these results, we have the flow equations

\[
\begin{align*}
\frac{dg}{dl} &= g^2 \left(\Gamma_1 f_2(z, z_1, z_2) - 2\Gamma_2 f_2(z, z, z_2)\right) \\
\frac{dz}{dl} &= g \left(-\Gamma_1 + 2\Gamma_2\right) \\
\frac{d\Gamma_1}{dl} &= g \left(\Gamma_2 + \frac{\Gamma_2^2}{z}\right) \\
\frac{d\Gamma_2}{dl} &= g \left(\Gamma_1 + \frac{2\Gamma_2^2}{z}\right) 
\end{align*} \tag{85} \]

Adding the second and fourth equations, and subtracting twice the third equation, we find:

\[
\frac{d}{dl} (z - 2\Gamma_1 + \Gamma_2) = 0 \tag{86} \]

Although we have only verified (86) to one-loop, it is, in fact, an exact relation which follows from the Ward identity for charge conservation, as we discuss in appendix C.

Since a constant of integration in (86) can be absorbed into a rescaling of frequencies, we can set \(\Gamma_1 = (z + \Gamma_2)/2\). Changing variables from \(\Gamma_2\) to \(\gamma_2 = \Gamma_2/z\) we have the equations:

\[
\begin{align*}
\frac{dg}{dl} &= g^2 \left(1 + 3 \left(1 - \frac{1}{1 + \gamma_2} \ln (1 + \gamma_2)\right)\right) \\
\frac{dz}{dl} &= z g \left(-\frac{1}{2} + \frac{3}{2} \gamma_2\right) \\
\frac{d\gamma_2}{dl} &= g(1 + \gamma_2)^2 \tag{87} \end{align*} \]

From the final equation, we see that \(\gamma_2\) increases at long length scales. This is not problematic since we made no assumptions about the smallness of \(\Gamma_2\). When \(\gamma_2\) becomes sufficiently large, \(z\) begins to grow, and \(g\), after an initial increase, begins to decrease. Since these equations are valid in the small \(g\) regime, it would appear that the flow improves their validity. However, \(\gamma_2\) and \(z\) diverge at a finite length scale. Since these equations include all orders in \(\gamma_2\), their breakdown signals the onset of non-perturbative physics.
It is useful, as a comparison, to consider the BCS interaction in a Fermi liquid. There, the flow equation for the BCS interaction, $V$, can be computed to all orders in perturbation theory:

$$ \frac{dV}{dl} = -V^2 $$

(88)

The one-loop RG result is the full story because there is only a geometric series of bubble diagrams. This equation also breaks down at a finite length scale – the coherence length. At this length scale, the non-perturbative physics of pairing takes over. Similarly, the breakdown of our flow equations (85) implies that non-perturbative physics – such as the formation of local moments – determines the behavior of the system. Such physics cannot be accessed perturbatively from the diffusive saddle point.

VIII. DISCUSSION

In this paper we have shown how the Schwinger-Keldysh dynamical formulation [26] can be applied in treating a disordered interacting electronic problem. We reproduce Finkelstein’s Renormalization Group equations for the interaction strength and conductance. In our approach, the RG procedure is carried out in a very simple way, in close resemblance to a $\phi^4$ theory (with cubic terms as well).

For the case of the diffusive Fermi liquid state, the calculation using Schwinger-Keldysh is very similar to the replica method. The two thermal indices for time-ordered and anti-time-ordered propagation play a similar role to that of the replica indices in the particular case of the diffusive Fermi liquid regime studied by Finkelstein. The disorder couples fields with different thermal indices (or replicas), while the interaction does not mix thermal indices (or replicas). The Schwinger-Keldysh indices, like the replicas, act in this example as simple book-keeping devices. In the replica calculation, the diffusive Fermi liquid state is replica symmetric. This is the underlying physical reason for the simplicity of the replica structure.

There should exist much more interesting saddle points where the replica symmetry is broken. One such point is the Wigner glass phase, which occurs in the limit of low electronic densities. As in the cases with other types of glasses, such as spin glasses, we know that replica symmetry breaking is connected to broken ergodicity. In the Schwinger-Keldysh approach we expect that broken ergodicity (and thus replica symmetry breaking) will manifest itself in subtleties related to the $\omega \to 0$ limit and the symmetry between time-ordered and anti-time-ordered products. The Schwinger-Keldysh provides a natural tool to study dynamical effects, which is a direction that we will explore.

ACKNOWLEDGEMENTS

We would like to thank Sudip Chakravarty, Eduardo Fradkin, Patrick Lee, Adrianus M.M. Pruisken, and Michael Stone for discussions. The authors would like to thank the Institute for Theoretical Physics, UCSB for hospitality during the workshops on Low-Dimensional Quantum Field Theory (1997) – where this work was begun – and Disorder and Interactions in the Quantum Hall Effect and Mesoscopic Systems (1998) – where this work was completed. This work was supported in part by the NSF under grant NSF-PHY 94-07194, grant NSF-DMR-94-24511 at the U. of Illinois (C.C.), and the A.P. Sloan Foundation (A.W.W.L.).

APPENDIX A: ELABORATION OF THE FIVE BASIC DIAGRAMS

The five basic diagrams of figure [7] are a schematic representation of the following 20 diagrams which renormalize $\Gamma_1$. 

17
FIG. 8. Diagrams (a) and (b) renormalizing $\Gamma_1$.

FIG. 9. Diagrams (c) and (d) renormalizing $\Gamma_1$. 
The corresponding diagrams which renormalize $\Gamma_2$ are:

```
(a)  (b)
(i)   (i)
(ii)  (ii)
(iii) (iii)
(iv)  (iv)
```

FIG. 11. Diagrams (a) and (b) renormalizing $\Gamma_2$. 
APPENDIX B: INTEGRALS

The following five logarithmically divergent integrals arise in the calculation of the diagram of figure 12 and diagrams (a)-(e). We define $x = Dq^2$ and integrate over the shells $\Lambda - d\Lambda < x < \Lambda, 0 < \omega < \Lambda$ and $\Lambda - d\Lambda < \omega < \Lambda, 0 < x < \Lambda$.

In the diagram of figure 4, there are no free frequencies; there is only a momentum integration.

\[
\frac{1}{4\pi D} \int dx \, D_0(x, \omega) = \frac{1}{4\pi D} \int_{\Lambda - d\Lambda}^{\Lambda} dx \, \frac{1}{x} = \frac{1}{4\pi D} \, d(\ln \Lambda)
\]

In diagrams (a)-(e), there are multiple propagators with different $z$'s. By rewriting these products of propagators as a sum over poles in $x$ and $\omega$, we reduce them to $d(\ln \Lambda)$ times non-divergent integrals. These integrals give non-trivial functions of the $z_i$'s.

\[
\frac{1}{2(2\pi)^2 D} \int dx \, d\omega \, D_0(x, \omega) D_2(x, \omega) = \frac{1}{2(2\pi)^2 D} \int_{\Lambda - d\Lambda}^{\Lambda} dx \, \int_0^\Lambda d\omega \, \frac{1}{x - iz\omega} \, \frac{1}{x - iz2\omega}
\]

\[
+ \frac{1}{2(2\pi)^2 D} \int_{\Lambda - d\Lambda}^{\Lambda} d\omega \, \int_0^\Lambda dx \, \frac{1}{x - iz\omega} \, \frac{1}{x - iz2\omega}
\]
Our disorder-averaged action $S$ would now like to indicate why this constraint follows from charge conservation. Let us imagine returning to disorder. The Ward identity which follows from charge conservation,

$$\int d\omega \int dx \lambda_0(\omega, x) \lambda_1(x, \omega) = \int d\omega \int dx \lambda_0(\omega, x) \lambda_1(x, \omega)$$

Similarly,

$$\int d\omega \int dx \int d\omega' \lambda_0(\omega, x) \lambda_1(x, \omega) \lambda_2(x, \omega) = \int d\omega \int dx \int d\omega' \lambda_0(\omega, x) \lambda_1(x, \omega) \lambda_2(x, \omega)$$

APPENDIX C: WARD IDENTITY

In section VI, we found that our one-loop RG equations imply that:

$$\frac{d}{dt} z = 2 \frac{d}{dt} \Gamma_s$$  \hspace{1cm} (C1)

We would now like to indicate why this constraint follows from charge conservation. Let us imagine returning to our disorder-averaged action $S_0 + S_{rand} + S_{int}$ for interacting electrons. Let us consider some fixed realization of the disorder. The Ward identity which follows from charge conservation,
\[ \partial_\mu \langle T \left( j_\mu (y) \psi^\dagger (x_1) \psi (x_2) \right) \rangle = i \delta (y-x_1) \langle T \left( \psi^\dagger (x_1) \psi (x_2) \right) \rangle - i \delta (y-x_2) \langle T \left( \psi^\dagger (x_1) \psi (x_2) \right) \rangle \]  

relates vertex renormalization (the left-hand-side) to the renormalization of the propagator (the right hand side). This is more transparent in momentum space:

\[ \Lambda_\mu (p,0) = \frac{\partial}{\partial p_\mu} (\omega - \epsilon_p - \Sigma (p)) \]  

\( \Lambda_\mu (p,0) \) is the Fourier transform of the correlation function with a current insertion (at zero momentum) on the left-hand-side of (C2). \( \Sigma \) is the self-energy. We focus on the \( \mu = 0 \) component of this equation:

\[ \Lambda_0 (p,0) = \frac{\partial}{\partial \omega} (\omega - \Sigma (p)) \]  

The equality between the left- and right-hand-sides is exemplified by the relation between diagrams 14(a) (the dashed line indicates the current insertion in the correlation function of the left-hand-side of (C2)) and 14(b).

As we indicate in figure 14(a), the diagrams contributing to the renormalization of the left-hand-side of (C4) are equivalent to those which determine the RG flow of \( \Gamma_s \).

Meanwhile, the diagrams contributing to the renormalization of the right-hand-side of (C4) renormalize \( z \). One way of seeing this is to note that the renormalization of the propagator determines the RG flow of \( z \) since the former is the renormalization of the term \( i\omega \psi^\dagger \psi \) in \( S_0 \) while the latter is the renormalization of the equivalent term in \( S_D \), namely \( \text{tr}[\omega Q] \). The factor of 2 on the right-hand-side results from the summation over the spin index \( \alpha \) in (b). This index is held fixed as an external index in the \( \Gamma_s \) renormalization.

In principle, we can derive the same result for disorder-averaged correlation functions directly within the \( \sigma \)-model by deriving the corresponding Ward identity. However, this is more cumbersome because the current operator and the gauge transformation rules are more complicated in the \( Q \)-field language.

---
