ABSTRACT

A method of synthesis crystalline yttrium citrate dihydrate was proposed as a result of the transformation of the freshly precipitated basic yttrium carbonate phase in a citric acid solution. The synthesis time was determined on the basis of composition analysis, structure and thermogravimetric studies of samples taken during the synthesis. The research methods used have shown that in the initial stage of the synthesis, the processes of citric acid sorption on basic yttrium carbonate and transformation of amorphous yttrium carbonate hydroxide into crystalline yttrium hydroxide occurs. It is only after 72 h of synthesis that the crystalline yttrium citrate dihydrate is formed.

• Synthesis crystalline yttrium citrate dehydrate.
• The synthesis time 72 h.
• Synthesis components: the freshly precipitated basic yttrium carbonate phase in a citric acid solution.

Introduction

The synthesis and properties of rare-earth elements citrates are studied not only from the theoretical point of view but also because of their practical application in modern technologies and yttrium citrate belongs to such relationship compound. Metal citrates were synthesized by precipitation reactions from homogeneous solutions of soluble metal salts and citric acid or sodium citrate [1–3]. Another method for obtaining the dispersion of metal citrates is the phase transformation method involving the reaction of a metal hydroxide or oxide with citric acid [4–6]. This method belongs to the group of methods that allow obtaining monodisperse colloids [7]. In the mentioned papers of transformation of metal hydroxide in a solution of citric acid into metal citrate, the structure, composition, thermal and spectroscopic properties of the obtained product were analyzed.

This paper contains supplementary information about kinetic of synthesis of monoclinic yttrium citrate dihydrate by phase transformation of amorphous yttrium carbonate hydroxide in citric acid solution [8]. The synthesis time was determined on the basis of composition (CH analysis), structure (PXRD method) and thermogravimetric studies of samples taken during the synthesis. The research methods used have shown that in the initial stage citric acid sorption on yttrium carbonate hydroxide and transformation of carbonate into crystalline yttrium hydroxide occurs. It is only after 72 h of synthesis that the crystalline yttrium citrate dihydrate is formed.

Materials and methods

Reagents and equipment
Yttrium chloride (YCl₃·6 H₂O) Sigma - Aldrich
Urea (CH₄N₂O) of the Polish Chemical Reagents
Citric acid (C₆H₈O₇·H₂O) of the Polish Chemical Reagents
Autoclave Engineers reactor
Perkin - Elmer CHN analyzer
Derivatograph-C apparatus (F. Paulik, J. Paulik, L. Erdey)
HZG – 4 Carl Zeiss Jena X-ray powder diffractometer

Procedure

Yttrium citrate dihydrate was obtained by transformation of freshly precipitated yttrium carbonate hydroxide in a citric acid solution.

In order to obtain yttrium carbonate hydroxide, the procedure given by Sprycha and Matijevic [9] was used, i.e.: solutions of: 0.02 mol/dm² yttrium chloride solution, 0.2 mol/dm³ urea solution were prepared, which were then filtered through 0.22 μm Milipore filters. Then 400 cm³ of

0.02 mol/dm³ yttrium chloride solution was mixed with 400 cm³ of urea solution and the mixture was heated in a 1000 cm³ beaker in a heating basket. After the appearance of a white precipitate, the suspension was continued to be heated for one hour before it was cooled in an ice-water bath. The resulting precipitate of basic yttrium carbonate (Y(OH)CO₃) was filtered on a Millipore membrane filter with a pore size of 0.22 µm. The filtered precipitate was ultrasonically dispersed in redistilled water, and the suspension was then filtered. The purification procedure was repeated until the filtrate conductivity was constant.

In order to obtain yttrium citrate dihydrate, washed yttrium carbonate hydroxide obtained from two syntheses (about 2 g) was placed in 200 cm³ of 0.1 mol/dm³ citric acid solution [8]. The suspension was then sonicated for 3 min, the pH was measured (pH = 2.71) and then transferred to an Autoclave Engineers reactor and heated at 100 °C for 3 days while stirring at 700 rpm. During the synthesis, after 12, 24, 48 and 72 h, samples of the slurry were taken from the reactor, filtered on a 0.22 µm Millipore filter, the filter cake washed and then dried at room temperature. The dried sediment was analyzed for the content of C and H as well as thermogravimetric and PXRD tests.

Results and discussion

The transformation time of yttrium carbonate hydroxide in a solution of citric acid into yttrium citrate was determined on the basis of results C and H analysis and thermogravimetric and PXRD studies of samples taken during the synthesis (after 12, 24, 48 and 72 h).

Using the CHN analyzer the following results of the percentage of the elements: carbon (C) and hydrogen (H) in the samples prepared as a result of hydrothermal synthesis at 100 °C were obtained, Table 1. The analysis of the samples no 1–4 composition for C and H contents indicates that during 48 h of synthesis the composition of the samples is close to that of citric acid (37.5% C and 4.2% H). This indicates that the analyzed samples contain a significant amount of unreacted citric acid that may have been absorbed on the tested sediment, this amount was calculated taking into account: the contents of C (3 column in Table 2), calculated content of carbon in yttrium hydroxide carbonate (6.63%) and calculated content of carbon in citric acid (37, 5%), the results of the calculations are shown in column 7 of Table 1. Analysis of C and H composition of sample taken after 72 hour of synthesis indicate that after this time of synthesis the yttrium citrate dihydrate was formed [8].
The use of freshly prepared yttrium carbonate hydroxide as starting reagent in the synthesis of yttrium oxide results lower temperature synthesis in comparison to conditions of synthesis of other metal citrates [4,5].

The course of the gravimetric analysis curves presented in Fig. 1 and indicates that the thermal decomposition of the tested compounds is multistage. Additionally for comparison the course of thermogravimetric curves for citric acid and yttrium carbonate hydroxide as the reference systems (starting reagents) is presented in this Fig. 1. Up to a temperature of 150 °C, the TG curve of citric acid is characterized by a slight (several percent) weight loss associated with the loss of hygroscopic water [10]. Above this temperature up to 300 °C there is a significant weight loss (~ 81%) associated with the decomposition of citric acid in the synthetic air [11]. The further weight loss associated with the oxidation of citric acid occurs up to 550 °C which is visible on the TG curves for the samples taken after 6, 12, 24 and 48 h. The thermogravimetry curves of the synthesized materials from 150 to 200 °C coincide with the TG curve of citric acid. The largest weight loss (~ 76%) for these samples is observed up to 258 °C. After heating the samples taken above 600 °C, 7, 4, 4, and 6% of the initial mass remains, respectively. This indicates a low content of yttrium compounds in the analyzed samples. Considering the analysis for C and H contents, it can be assumed that the samples contained a significant amount of unreacted citric acid. The course of TG curve of the sample taken after 72 h of synthesis differ significantly from previous one and percent of remains of mass after heating it above 700 °C agree with contents of yttrium oxide in yttrium citrate dihydrate [8].

The samples taken from the reactor after 12, 24, 48 and 72 h synthesized at 100 °C were subjected to the XRD analysis. The diffraction patterns of the samples (except for the sample after 12 h) are given in Fig. 2. The analysis of the reflection in the PXRD pattern of the samples taken during the synthesis after 12, 24 and 48 h of synthesis indicated the presence of reflections characteristic of
Fig. 2. PXRD pattern of the samples taken after 24, 48 and 72 h of synthesis.

Table 3
Calculated amount of yttrium species in samples collected during the synthesis of yttrium citrate.

| Sample no | YOHCO$_3$ [%] | Y(OH)$_3$ [%] | Y(OH)CO$_3$ [%] | Sum of column 3 + 4 [%] |
|-----------|---------------|----------------|------------------|-------------------------|
| 1         | 9.41          | 3.8            |                  |                         |
| 2         | 8.07          | 2.7            | 4.6              | 7.3                     |
| 3         | 5.38          | 3.5            | 3.0              | 6.5                     |
| 4         | 8.07          | 2.5            | 3.5              | 6.0                     |

An example of fitting calculations to the diffraction pattern for sample no 2 is shown in Fig. 3. The phase analysis carried out confirms the results obtained with the TG method with a high content of citric acid in the samples taken during synthesis. It should be noted that the amount of amorphous phase in the sample, which could have been yttrium carbonate hydroxide, was not determined by XRD. In turn, calculations based on the carbon content of samples no 2 – 4 did not take into account the presence of yttrium hydroxide, which could have arisen as a result of hydrolysis of yttrium carbonate during the synthesis of yttrium citrate. The results of the content of yttrium carbonate hydroxide and yttrium hydroxide are given in Table 3. As can be seen, the content of both compounds in the tested samples is comparable. The total content of yttrium forms in the sample can be determined on the basis of TG analysis by converting the content of yttrium oxide after heating.
the sample to 750 °C based on the distribution of equal amounts of yttrium hydroxide carbonate and yttrium hydroxide. A summary of the results of the content of yttrium forms in the samples taken during the synthesis is given in Table 4. As can be seen, the sum of the calculated content of yttrium hydroxide carbonate (column 1 of Table 4) based on the content of carbon and yttrium hydroxide determined by the XRD method is close to that estimated on the basis of thermogravimetric analysis of carbonate content (last column of the Table 3).
