The paper presents changes in the color and acidity of *Fagus sylvatica* L. in the process of heat treatment of wood with saturated water steam in the temperature range $t = 105 – 135^\circ C$ during $\tau = 3$ to 12 hours. The light white-gray color of beech wood with a yellow tint changes on the pale pink, red-brown to a brown-red color in the heat treatment process. The color changes of beech wood expressed in the form of the total color difference are in the range of values $\Delta E^* = 1.97 – 26.85$. Due to the hydrolysis of hemicelluloses, the acidity changes in the process of thermal treatment of wet beech wood. Decrease in acidity of beech wood in the range of temperatures $t = 105 – 135 ^\circ C$ and time $\tau = 3 – 12$ hours is in the range of pH values $= 4.9$ to $3.4$. The dependence of the total color difference $\Delta E^*$ on the change in acidity of beech wood is described by the polynomial of function II. degree. The above knowledge is a suitable tool for evaluating the degree of change in beech wood color in the technological process based on the change in pH of wood.

KEYWORDS: Wood, *Fagus sylvatica* L., acidity, color difference, thermal treatment, saturated water steam.

INTRODUCTION

Wood placed in the environment of hot water, saturated water steam or saturated humid air is heated and its physical, mechanical as well as chemical properties change. Thermal treatment of wood, besides physical and mechanical changes applied in the process of manufacturing veneers, plywood, bentwood furniture or pressed wood are accompanied with the changes in chemical properties and color of wood (Kollmann and Cote 1968, Sergovskij and Rasev 1987, Trebula 1986, Tolvaj et al. 2010, Dzurenda and Orlowski 2011, Dzurenda 2013, Baranski et al. 2017, Sikora et al. 2018). In the past, color changes when wood becoming darker during the steaming
process were used to remove the undesirable color differences between light colored sapwood and dark colored heartwood or to eliminate wood stain colors as a result of mold. In recent times, research into thermally modified wood has been focused on the issue of the color change of specific wood species into more or less bright hues or wood imitation of domestic or exotic tree species (Molnar and Tolvaj 2002, Tolvaj et al. 2009, Dzurenda 2014, 2018a,b,c, Barcik et al. 2015, Baranski et al. 2017).

Free water in the lumens of wood cells is a dilute aqueous solution of sugars, organic acids and salts of calcium, magnesium, potassium, sodium, which are transported by the root system to the living tree (Čudinov 1968, Blažej et al. 1975, Zevenhoven 2001, Pňakovič and Dzurenda 2015). The value of the acidity of the aqueous solution in deciduous wood, in the range of pH values 5.5 – 4.8 (Sandermann and Rothkamm 1956, Solár 2014, Geffert et al. 2019).

The effect of thermal on wet wood is also initiated by chemical changes in wood. The first chemical reactions include partial hydrolysis of hemicelluloses and extraction of water-soluble substances (Fengel and Wegener 1984, Bučko 1995, Solár 2004, Sundqvist et al. 2006, Samešová et al. 2018). Depending on the temperature and duration of action of the hydrolysis products, which are acetic acid and formic acid, degradation of polysaccharides occurs. During the thermal treatment of wood, dehydration of pentoses to 2-furaldehyde as well as oxidation of carbohydrates also occur. New chromophoric groups begin to form in lignin, causing the wood to change color (Fengel and Wegener 1984, Bučko 1995, Hon and Shiraishi 2001, Solár 2004, Sundqvist et al. 2006, Geffert et al. 2019).

The aim of the work is to determine the changes in acidity of beech wood in the technological process of wood color modification with saturated water steam in the temperature range \( t = 105-135°C \) during 12 hours and to determine the dependence of the total color change of beech wood \( (\Delta E^*) \) in CIE \( L^* a^* b^* \) on the pH value of beech wood obtained by the heat treatment process.

### MATERIAL AND METHODS

**Material**

The wood of *Fagus sylvatica* L. in the form of blanks with dimensions: thickness of 40 mm, width of 90 mm, and length of 750 mm in 260 pieces was divided into 13 groups of 20 pieces in one group. The initial moisture content of wet beech wood was in the range of values \( w = 54.7 \) to \( 58.2\% \). Group 1 blanks were not thermally treated. The other blanks were divided into 12 groups of 20 pieces each and thermally treated with saturated water steam at \( t = 105°C, t = 125°C \) and \( t = 135°C \) for 3, 6, 9 and 12 h. Thermal treatment of beech wood with saturated water steam was carried out in a pressure autoclave APDZ 240 (Himmasch AD, Haskovo, Bulgaria) installed in the company Sundermann s.r.o., Banská Štiavnica (Slovakia).

**Methods**

The conditions of thermal treatment of beech wood with saturated water steam with indicating the sampling time intervals during the thermal treatment \( v \) are shown in Fig. 1. The thermal process of beech wood color modification was performed in an APDZ 240 autoclave (Himmasch AD, Haskovo, Bulgaria) at a higher saturated water steam pressure than atmospheric pressure. Saturated water steam temperatures in individual color adjustment modes are given in Tab. 1.
The temperatures $t_{\text{max}}$ and $t_{\text{min}}$ are the temperature intervals at which saturated water steam is fed into the autoclave to carry out the technological process. Temperature $t_4$ is the temperature of the saturated water steam in the autoclave after the water steam pressure in the autoclave has been reduced to atmospheric pressure to allow safe opening of the pressure equipment and sampling after the time thermal treatment 3, 6, 9, and 12 h.

Tab. 1: Modes of color modification of beech wood with saturated water steam.

| Temperature of saturated water steam | $t_{\text{min}}$ | $t_{\text{max}}$ | $t_4$ | Length of time wood is exposed to color modification |
|-------------------------------------|------------------|------------------|-------|-----------------------------------------------|
| Mode I                             | 102.5            | 107.5            | 100   | $\tau_1 = 3$ h | $\tau_2 = 6 (+0.5^a)$ h | $\tau_3 = 9 (+1.0^a)$ h | $\tau_4 = 12 (+1.5^a)$ h |
| Mode II                            | 122.5            | 127.5            | 100   |                                               |
| Mode III                           | 132.5            | 137.5            | 100   |                                               |

Note: a time for taking out the specimens.

The moisture content and pH of the wet thermally treated wood were determined by taking samples from the autoclave and cooling the wood to ambient temperature. The moisture content of wet beech wood above the fiber saturation point (BNV) was determined by the gravimetric method according to the standard STN EN 13183-1 (2003).

The pH of wet beech wood was measured using a pH-meter SI 600 with a Lance FET + H puncture probe (Sentron, Roden, Netherlands). A hole with a diameter of 12 mm was created using an accu drill (DeWalt DCD791NT, Germany). Drilling sawdust was pressed into the hole and the LanceFET + H sensor head (Geffert et al. 2019) was inserted into the wet sawdust. After about 60 seconds of stabilization, the pH value was read on a SI 600 pH-meter (Sentron, Roden, Netherlands).

Color-modified beech wood with saturated water steam treatment technology is used as a material for the production of furniture, flooring or interior tiles in a dry state. For this reason, samples of uncooked and thermally treated beech wood were dried by a gentle drying regime to a final moisture content of $w = 12 \pm 0.5\%$. Subsequently, the surface of the dry blanks was machined on a FS 200 (BENET Trading, Kvasiny, Slovakia) milling machine.

The color of untreated and thermally treated beech wood in the CIE L* a* b* color space was determined using the Color Reader CR-10 (Konica Minolta, Japan). D65 light source with an
illuminated area of 8 mm was used. Color was evaluated based on changes in CIE L* a* b* color space on the coordinate of brightness L* the red color a*, the yellow color b* and the total color difference ∆E*. The total color difference value is described by the Eq. 1.

\[
\Delta E^* = \sqrt{(L_2 - L_1)^2 + (a_2 - a_1)^2 + (b_2 - b_1)^2}
\]  

where:  
\( L_1, a_1, b_1 \) - values on the color space coordinates of the surface of dried milled thermally untreated beech wood.  
\( L_2, a_2, b_2 \) - values on the color space coordinates of the surface of dried milled thermally treated beech wood.

Using the STATISTICA 12 program (V12.0 SP2, USA), graphical and mathematical dependences of pH = f (t, τ) and ∆E* = f (t, τ) were determined from the measured data in the temperature range: t = 105 to 135°C and time τ = 3 to 12 h. The programmatic processing of the measured results partially eliminated the effect of measurement errors due to wood heterogeneity and a direct pH measurement method (Geffert et al. 2019).

RESULTS AND DISCUSSION

The light white-gray color with a yellow tinge of dry beech wood of uncooked beech wood was identified in the color space CIE L* a* b* by the coordinates \( L^* = 76.6 \pm 2.3; \ a^* = 6.9 \pm 1.8; \ b^* = 19.8 \pm 1.7 \). The values given are comparable to the values of color coordinates given for beech wood by the authors (Babiak et al. 2004, Dzurenda 2014, Meints et al. 2017).

In the heat treatment process, the light white-gray color changes to pale pink, red-brown to dark brown shades. The degree of coloring of beech wood by heat treatment with saturated steam is dependent on the temperature and duration of the technological process, as evidenced by Fig. 2.

![Fig. 2: Changes in the color of beech wood during thermal modification.](image)

Information on changes in the color of beech wood during thermal treatment on the coordinate of brightness \( L^* \), red color \( a^* \), yellow color \( b^* \) and the total color difference \( \Delta E^* \) is given in Tab. 2.
Tab. 2: Measured values on the coordinates \( L^* \), \( a^* \), \( b^* \) in the color space CIE \( L^* a^* b^* \), values of the total color difference \( \Delta E^* \) of beech wood during the process of thermal modification.

| Temperature of saturated water steam | Time of thermal modification of beech wood color |
|-------------------------------------|-----------------------------------------------|
|                                     | 3 h  | 6 h  | 9 h  | 12 h                        |
| \( t_I \) = 105 ± 2.5°C             | \( L^* = 75.8 \pm 0.9 \) | \( L^* = 70.5 \pm 0.8 \) | \( L^* = 68.9 \pm 1.0 \) | \( L^* = 67.4 \pm 1.2 \) |
|                                     | \( a^* = 8.5 \pm 0.5 \) | \( a^* = 10.7 \pm 0.4 \) | \( a^* = 10.5 \pm 0.4 \) | \( a^* = 10.3 \pm 0.6 \) |
|                                     | \( b^* = 19.2 \pm 0.4 \) | \( b^* = 20.2 \pm 0.4 \) | \( b^* = 20.2 \pm 0.5 \) | \( b^* = 19.5 \pm 0.5 \) |
|                                     | \( \Delta E^* = 1.97 \) | \( \Delta E^* = 7.25 \) | \( \Delta E^* = 8.64 \) | \( \Delta E^* = 9.84 \) |
| \( t_{II} \) = 125 ± 2.5°C         | \( L^* = 70.5 \pm 0.9 \) | \( L^* = 64.7 \pm 1.2 \) | \( L^* = 62.9 \pm 1.0 \) | \( L^* = 59.7 \pm 0.9 \) |
|                                     | \( a^* = 10.3 \pm 0.4 \) | \( a^* = 11.9 \pm 0.4 \) | \( a^* = 12.5 \pm 0.4 \) | \( a^* = 12.2 \pm 0.4 \) |
|                                     | \( b^* = 19.8 \pm 0.6 \) | \( b^* = 17.9 \pm 0.5 \) | \( b^* = 18.5 \pm 0.4 \) | \( b^* = 19.8 \pm 0.3 \) |
|                                     | \( \Delta E^* = 7.03 \) | \( \Delta E^* = 13.01 \) | \( \Delta E^* = 14.80 \) | \( \Delta E^* = 17.70 \) |
| \( t_{III} \) = 135 ± 2.5°C        | \( L^* = 66.6 \pm 0.6 \) | \( L^* = 60.7 \pm 1.2 \) | \( L^* = 54.2 \pm 0.8 \) | \( L^* = 50.4 \pm 1.7 \) |
|                                     | \( a^* = 11.6 \pm 0.2 \) | \( a^* = 12.5 \pm 0.5 \) | \( a^* = 12.5 \pm 0.4 \) | \( a^* = 12.6 \pm 0.4 \) |
|                                     | \( b^* = 18.7 \pm 0.3 \) | \( b^* = 19.4 \pm 0.7 \) | \( b^* = 19.5 \pm 0.6 \) | \( b^* = 18.8 \pm 0.6 \) |
|                                     | \( \Delta E^* = 11.15 \) | \( \Delta E^* = 16.89 \) | \( \Delta E^* = 23.10 \) | \( \Delta E^* = 26.85 \) |

From the difference of the values on the brightness coordinate \( L^* \) from the value \( L_0^* = 76.8 \) of thermally untreated beech wood and the values of \( L_4^* \) of thermally treated beech wood after 12 hours at individual temperatures of thermal treatment it follows that while at temperature \( t_I = 105 \pm 2.5°C \) thermal treatment the brightness decreased by \( \Delta L_4^* = -9.4 \), so at thermal treatment with temperature \( t_{II} = 125 \pm 2.5°C \) the brightness decreased by \( \Delta L_4^* = -17.1 \) and at temperature \( t_{III} = 135 \pm 2.5°C \) the brightness decreased by up to \( \Delta L_4^* = -26.4 \). The decrease in the brightness of beech wood with an increase in temperature is not directly proportional. At higher temperatures of the heat treatment process, the decrease in brightness is greater and the darkening of beech wood is more pronounced.

A decrease in values of the coordinate of lightness \( L^* \) of thermally treated wood is in line with reports of wood darkening in the processes such as wood steaming (Varga and Van der Zee 2008, Tolvaj et al. 2009, 2010, Dzurenda 2014, 2018b,c, Hajdarski and Deliiski 2016, Banski and Dudiak 2019), or drying in warm humid air or high temperature wood drying in a superheated steam environment (Klement and Marko 2009, Dzurenda and Deliiski 2012a,b, Baranski et al. 2017).

Changes in the chromatic coordinate of red color \( a^* \) have an increasing tendency. The value of the red color of native wood \( a_0^* = 6.9 \) increases during 12 hours in a thermal process with the temperature of saturated water steam \( t_I = 105 \pm 2.5°C \) to the value \( a_4^* = 10.3 \) and at the temperature of water steam \( t_{III} = 135 \pm 2.5°C \) to \( a_4^* = 12.6 \). The magnitudes of the changes on the red coordinate \( a^* \) are significantly smaller compared to the changes on the luminance coordinate \( L^* \). The analysis of the influence of the parameters: temperature and duration of the technological process shows that with increasing temperature the values on the red coordinate \( a^* \) increase. The largest increase in the values of \( \Delta a^* \) manifested by reddening of beech wood is in the first 6 hours of the technological process, a similar statement is given by the authors Banski and Dudiak (2019).

On the coordinate yellow color \( b^* \), the changes are slight and contradictory, oscillating in a tolerance of ±1.6 around the value \( b^* = 18.1 \). They point to the formation of less stable compounds with absorption of the electromagnetic radiation spectrum with a yellow wavelength
of 560 nm. Said compounds react with water or extraction products to form further thermal decomposition products with lower or zero absorption of the yellow wavelength electromagnetic radiation spectrum.

Color changes in beech wood during the thermal treatment, in addition to identification by means of values $L^*, a^*, b^*$ in the color space CIE $L^* a^* b^*$, are aptly characterized by the parameter - the total color difference $\Delta E^*$. The dependence of the change of the total color difference $\Delta E^*$ on the temperature $t$ and time $\tau$ of beech wood during heat treatment of wood at saturated water steam temperatures in the range from $t = 105$ to $135^\circ C$ and time $\tau = 3 – 12$ h., is shown in the form of a 3D diagram in Fig. 3 and is mathematically described by Eq. 2.

$$\Delta E^* = 128.919 - 2.384 \cdot t - 1.008 \cdot \tau + 0.108 \cdot t^2 + 0.029 \cdot t \cdot \tau - 0.085 \cdot \tau^2$$ (2)

where:
- $t$ - temperature of the saturated water steam °C,
- $\tau$ - time wood is exposed to color modification in hours.

Under the influence of heat, in the process of thermal treatment of wet beech wood, the processes of hydrolysis of hemicelluloses take place, which are reflected in the change of acidity of beech wood. Measured values of moisture $w$ and acidity $pH$ of beech wood before the heat treatment process and during heat treatment of beech wood in the technological process measured at time 3, 6, 9 and 12 h. are listed in Tab. 3

### Tab. 3: Average values of moisture content and acidity of beech wood in the process of heat treatment of wood.

| Temperature of saturated water steam | Time of thermal modification of beech wood |
|-------------------------------------|------------------------------------------|
|                                     | 0 h  | 3 h  | 6 h  | 9 h  | 12 h |
| $t_I = 105 \pm 2.5^\circ C$         | 56.9 | 5.1  | 49.6 | 4.9  | 49.2 | 4.7  | 49.5 | 4.6  | 48.9 | 4.4  |
| $t_{II} = 125 \pm 2.5^\circ C$     | 55.8 | 5.2  | 44.3 | 4.3  | 44.9 | 4.0  | 45.2 | 3.9  | 44.7 | 3.8  |
| $t_{III} = 135 \pm 2.5^\circ C$    | 56.5 | 5.1  | 46.5 | 3.8  | 45.8 | 3.7  | 46.0 | 3.5  | 44.3 | 3.4  |
The moisture values of the thermally treated beech wood after cooling to ambient temperature were lower than the moisture of the wood before the thermal treatment. Reduction of beech wood moisture content by $\Delta w = 6.9$ to 12.6% is caused by evaporation of water from wood to saturated water steam in autoclave during cooling to temperature $t = 100^\circ$C before sampling from autoclave and vaporization of water from wood to atmosphere during cooling of wood to ambient air temperature. The source of heat for evaporation and vaporization of water from wood is the heat accumulated during the heating of the wood to the required technological temperature (Dzurenda and Deliiski 2000, Dzurenda 2018d).

Changes in the acidity of beech wood in the heat treatment process are a confirmation of the known knowledge about the decrease in the pH of wet wood (Bučko 1995, Sundqvist et al. 2006, Samešova et al. 2018, Geffert et al. 2019). From experimentally measured pH values of beech wood during heat treatment of wood with saturated steam in the range of temperatures from $t = 105$ to 135°C and time $\tau = 3 – 12$ h, a graphical dependence of the change in acidity on temperature and time was determined in the form of a 3D diagram (Fig. 4).

Changes in the acidity values of wet beech wood at the temperature of saturated water steam in the range of values $t = 105 – 135^\circ$C and time $\tau = 3 – 12$ hours are given by a mathematical equation in the form:

$$pH = 5.0217 + 0.0236 \cdot t - 0.1021 \cdot \tau - 0.00022 \cdot t^2 + 0.0002 \cdot t \cdot \tau + 0.0019 \cdot \tau^2$$  

where: $t$ – temperature of the saturated water steam °C,
$\tau$ – time wood is exposed to color modification in hours.

The course of changes in the total color difference $\Delta E^*$ on the acidity of wet beech wood in the process of thermal treatment in the temperature range $t = 105 – 135^\circ$C and the time of the technological process $\tau = 3 – 12$ h. is shown in Fig. 5.
The dependence of the total color difference of beech wood on the value of acidity is mathematically described by the function:

$$\Delta E^* = 7.1978 \cdot (pH)^2 - 73.131 \cdot (pH) + 190.34 \tag{4}$$

where: $pH$ - acidity value of wet beech wood.

A similar dependence of the total color difference of wood on the $pH$ value of wet thermally treated beech wood is presented in the work Dzurenda et al. (2020).

It can be seen from the resulting dependence that the color of the heat-treated beech wood acquires darker shades due to the temperature of the saturated water steam and the modification time. The $pH$ values of wet thermally treated wood, depending on the temperature of the saturated steam and the time of treatment decrease, i.e. they have a more acidic $pH$, which can be clearly seen in the given dependence the darker the shade the lower (more acidic) $pH$. The dependence of the total color difference $\Delta E^*$ on the change in the acidity of beech wood in the thermal process is a suitable tool for evaluating the achieved color change based on the $pH$ of beech wood in the technological process.

CONCLUSIONS

(1) The paper presents the results of color change and acidity of Fagus sylvatica L. wood in the process of heat treatment of wood with saturated water steam at temperatures: $t_I = 105 \pm 2.5^\circ C$, $t_{II} = 125 \pm 2.5^\circ C$ and $t_{III} = 135 \pm 2.5^\circ C$ for $\tau = 12$ hours.

(2) The color of beech wood changes from a light white-gray color with a yellow to pale pink, red-brown to a brown-red color in the heat treatment process. The magnitude of color changes is mathematically described by the equation $\Delta E^* = 128.919 - 2.384 \cdot t - 1.008 \cdot \tau + 0.108 \cdot t^2 + 0.029 \cdot t \cdot \tau - 0.085 \cdot \tau^2$.

(3) The rate of change of acidity from $pH = 5.1$ to $pH = 3.4$ in the process of thermal modification of beech wood color at temperature $t$ time $\tau$ is described by the equation: $pH = 5.0217 + 0.0236 \cdot t - 0.1021 \cdot \tau - 0.00022 \cdot t^2 + 0.0002 \cdot t \cdot \tau + 0.0019 \cdot \tau^2$.

(4) The dependence of the total color change $\Delta E^*$ of beech wood on the acidity of thermally treated wood in the range of values $pH = 4.9 - 3.4$ is described by the equation: $\Delta E^* = 7.1978 \cdot (pH)^2 - 73.131 \cdot (pH) + 190.34$.
