Abstract

Using suitable deformations of simplicial trees and the duality theory for median
sets, we show that every free action on a median set can be extended to a free and
transitive one. We also prove that the category of median groups is a reflective full
subcategory of the category of free actions on pointed median sets.

2000 Mathematics Subject Classification: Primary 20E08; Secondary 20E05, 20E06
Key words and phrases: free action, transitive action, simplicial tree, median set
(algebra), median group, folding, free group, free product, spectral space, coherent
map, distributive lattice with negation.

Introduction

Given an action $G \times \mathcal{X} \rightarrow \mathcal{X}$ of a group $G$ on a mathematical structure $\mathcal{X}$, a natural
question to ask is whether it could be extended to a transitive action $\hat{G} \times \hat{\mathcal{X}} \rightarrow \hat{\mathcal{X}}$ on
a structure $\hat{\mathcal{X}}$ of the same type with $\mathcal{X}$. Though in the simplest case when $\mathcal{X}$ is a set,
this question has a positive answer, the problem is not at all easy in the case of actions
on certain specific structures. In the present paper, having three parts, we consider the
question above in the frame of actions on generalized trees.

Using the connection between Lyndon length functions and actions on $\Lambda$-trees, as
well as string-rewriting systems techniques, Ian Chiswell and Thomas Müller obtained
quite recently the following nice result

Theorem (cf. [17, Theorem 5.4.]) Let $G$ be a group acting freely and without
inversions on a $\Lambda$-tree $\mathcal{X}$, where $\Lambda$ is a totally ordered abelian group. Then there exists

*The author gratefully thanks Professor Thomas Müller for sending him his nice joint work with Ian
Chiswell “Embedding theorems for tree-free groups”, which motivated and inspired the present work.
a group $\hat{G}$ acting freely, without inversions, and transitively on a $\Lambda$-tree $\hat{X}$, together
with a group embedding $G \to \hat{G}$ and a $G$-equivariant isometry $X \to \hat{X}$.

The main goal of the present work is to extend the result above in two directions: on the one hand, the $\Lambda$-trees, where $\Lambda$ is a totally ordered abelian group, are replaced
by more general arboreal structures (median sets, in particular, faithfully full $\Lambda$-metric median sets (cf. \[3, 1.3\]), where $\Lambda$ is an abelian $l$-group); on the other hand, the free
actions without inversions are replaced by actions of a more general type involving bicrossed products of groups. The method of proof is also different from that used in
\[17\]: it is based on a suitable procedure of deformation of simplicial trees into more
general arboreal structures \[4\] as well as on the duality theory for median sets (cf. \[3\]).

The paper has three parts. The part I is devoted to free actions on median sets. The
results of part I will be applied in the part II to free actions on more general $\Lambda$-trees,
where $\Lambda$ is an arbitrary abelian $l$-group, not necessarily totally ordered, while the part
III will be devoted to more general actions, not necessarily free, on generalized trees.

In order to state the main results of the part I of the paper, we introduce (recall) some basic notions. More details will be given in Section 1 having a preliminary character.

**Definition 1.** By a median set (or median algebra \[1\]), we understand a set $X$ together with a ternary operation $m : X^3 \to X$ satisfying the following three equational axioms

1. **Symmetry:** $m(x, y, z) = m(y, x, z) = m(x, z, y)$
2. **Absorptive law:** $m(x, y, x) = x$
3. **Selfdistributive law:** $m(m(x, y, z), u, v) = m(m(x, u, v), m(y, u, v), z)$

The element $m(x, y, z)$ is called the median of the triple $(x, y, z)$.

Notice that (M 3) can be replaced by

(M 3') $m(m(x, u, v), m(y, u, v), x) = m(x, u, v)$

In particular, taking $u = y,v = z$, we obtain $m(m(x, y, m(x, y, z))) = m(x, y, z)$ for all $x, y, z \in X$. For $x, y \in X$, we denote $[x, y] := \{z \in X | m(x, y, z) = z\} = \{m(x, y, z) | z \in X\}$.

Notice that $[x, y] = [y, x]$, and $u, v \in [x, y] \implies [u, v] \subseteq [x, y]$.

**Definition 2.** Let $X = (X, m)$ be a median set.

1. A subset $M \subseteq X$ is said to be convex if $[x, y] \subseteq M$ for all $x, y \in M$. In
   particular, $[x, y]$ is convex for all $x, y \in X$.
2. A nonempty convex subset $M \subseteq X$ is retractible if for all $x \in X$ there exists
   (uniquely) $\psi(x) \in M$ such that $[x, a] \cap M = [\psi(x), a]$ for all (for some) $a \in M$; call
   the map $\psi : X \to X$ with $\psi(X) = M$ the folding associated to $M$.
3. $X$ is said to be locally linear if $[x, y] = [x, z] \cup [z, y]$ for all $x, y \in X, z \in [x, y]$.
4. $X$ is called simplicial (or discrete) if $[x, y]$ is finite for all $x, y \in X$.

Notice that, though median sets could seem too general to be considered genuinely
treelike”, they are, however, very well suited for the study of various natural arboreal

\[1\) Compare with the procedure used in \[3, Proposition 4.2\] to extend a given locally linear median

group structure on a component of a suitable tree of groups to the associated fundamental group.
and metric structures on groups and rings - see for instance [3], [5] - [10], [12], [15]. In particular, a key role is played by median groups determined by the first main result of the part I of the paper. Let $(G, m)$ be a group, together with an action from the left $G \times X \to X$, $(g, x) \mapsto g \cdot x$ on a nonempty median set $X = (X, m)$, while we take as morphisms $(G, X) \to (G', X')$ the pairs $(\psi_0, \psi)$, where $\psi_0 : G \to G'$ is a group morphism, and $\psi : X \to X'$ is a morphism of median sets, compatible with the actions, i.e. $\psi(g \cdot x) = \psi_0(g) \cdot \psi(x)$ for all $g \in G, x \in X$. We denote by $\text{FAMS}$ the full subcategory of $\text{AMS}$ whose objects are the free actions on nonempty median sets, while by $\text{FTAMS}$ we denote the full subcategory of $\text{FAMS}$ consisting of the free and transitive actions on nonempty median sets.

We consider also the category $\text{FAPMS}$ of free actions on pointed median sets having as objects the systems $(G, X, x_0)$, where $G$ is a group acting freely on a median set $X = (X, m)$, while $x_0 \in X$ is a fixed base point. The morphisms in $\text{FAPMS}$ are the morphisms in $\text{FAMS}$ which preserve the base points. The category $\text{MG}$ of median groups, with naturally defined morphisms, is equivalent with $\text{FTAMS}$ and is identified with a full subcategory of $\text{FAPMS}$, by taking the neutral element 1 of a median group $G = (G, m)$ as the base point of its underlying median set.

A strong connection between free actions on median sets and median groups is described by the first main result of the part I of the paper.

**Theorem 1.** Let $H$ be a group acting freely on a nonempty set $X$. Fix a basepoint $b_1 \in X$. We denote by $\mathcal{M}(X)$ the set of all median operations $m : X^3 \to X$ which are compatible with the action of $H$, i.e. $m(hx, hy, hz) = h \cdot m(x, y, z)$ for all $h \in H, x, y, z \in X$. Let $\mathcal{M}(X)(\mathcal{M}_s(X))$ be the subset of $\mathcal{M}(X)$ consisting of those median operations which are locally linear (simplicial). Then there exists a group $\hat{H}$ containing $H$ as its subgroup, together with an embedding $\iota : X \to \hat{H}$ and a retract $\varphi : \hat{H} \to X$ such that the following hold.

1. The maps $\iota$ and $\varphi$ are $H$-equivariant, i.e. $\iota(h \cdot x) = h \iota(x), \varphi(hu) = h \cdot \varphi(u)$ for all $h \in H, x \in X, u \in \hat{H}$.

2. $\iota(b_1) = 1$, so $\iota(Hb_1) = H$, and $\iota(X)$ generates the group $\hat{H}$.

3. Every $m \in \mathcal{M}(X)$ extends uniquely to a ternary operation $\hat{m} : \hat{H}^3 \to \hat{H}$ such that $(\hat{H}, \hat{m})$ is a median group and the map $\iota \circ \varphi : \hat{H} \to \hat{H}$ is a folding identifying $X$ with a retractable convex subset of the median set $(\hat{H}, \hat{m})$.

\[\text{2) The median sets and the median groups form proper subclasses of the larger class of connected median groupoids of groups introduced in [3], [4] as a frame for an extension of the Bass-Serre theory to actions on more general arboreal structures.}\]
(4) The median group \((\hat{H}, \hat{m})\) is locally linear (simplicial) provided \(m \in M_1(X)\) \((m \in M_s(X))\).

The other two main results of the part I of the paper are concerned with the construction of two functors on the category \(\text{FAMS}\) with suitable universal properties.

**Theorem 2.** Let \(H\) be a group acting freely on a nonempty median set \(X = (X, m)\). Then there exists a group \(\hat{H}\) acting freely on a median set \(\hat{X} = (\hat{X}, \hat{m})\), together with a group embedding \(\iota_0 : H \rightarrow \hat{H}\) and a \(H\)-equivariant embedding of median sets \(\iota : X \rightarrow \hat{X}\) such that \(\iota(X) \subseteq \hat{H}(x)\) for some \((\text{for all})\) \(x \in X\), and the following universal property is satisfied.

\((\text{RTUP})\) For every group \(\hat{H}\) acting freely on a median set \(\hat{X} = (\hat{X}, \hat{m})\) and for every morphism \((\psi_0, \psi) : (H, X) \rightarrow (\hat{H}, \hat{X})\) in \(\text{FAMS}\) such that \(\psi(X) \subseteq \hat{H}\psi(x)\) for some \((\text{for all})\) \(x \in X\), there exists uniquely a morphism \((\hat{\psi}_0, \hat{\psi}) : (\hat{H}, \hat{X}) \rightarrow (\hat{H}, \hat{X})\) in \(\text{FAMS}\) such that \(\hat{\psi}_0 \circ \iota_0 = \psi_0, \hat{\psi} \circ \iota = \psi\).

Call the (unique up to a unique isomorphism) free action \((\hat{H}, \hat{X})\), extending \((H, X)\) and satisfying \((\text{RTUP})\), the relatively-transitive closure of the free action \((H, X)\).

By iterating the functorial construction above we obtain

**Theorem 3.** Let \(H\) be a group acting freely on a nonempty median set \(X\). Then there exists a group \(\delta\) acting freely and transitively on a median set \(X\), together with an embedding \((\iota_0, \iota) : (H, X) \rightarrow (\delta, X)\) in the category \(\text{FAMS}\) such that the following universal property is satisfied.

\((\text{TUP})\) For every group \(\hat{H}\) acting freely and transitively on a median set \(\hat{X}\) and for every morphism \((\psi_0, \psi) : (H, X) \rightarrow (\hat{H}, \hat{X})\) in \(\text{FAMS}\), there exists uniquely a morphism \((\Psi_0, \Psi) : (\delta, X) \rightarrow (\hat{H}, \hat{X})\) in \(\text{FTAMS}\) such that \(\Psi_0 \circ \iota_0 = \psi_0, \Psi \circ \iota = \psi\).

Call the (unique up to a unique isomorphism) free and transitive action \((\delta, X)\) extending \((H, X)\), with the property \((\text{TUP})\), the transitive closure of the free action \((H, X)\).

In category and median group theoretic terms, Theorem 3 can be rephrased as follows.

**Theorem 3’.** \(\text{MG}\) is a reflective full subcategory of \(\text{FAPMS}\), i.e. the embedding functor \(\text{MG} \rightarrow \text{FAPMS}\) has a left adjoint which embedds every free action on a pointed median set into the median group freely generated by it.

The part I of the paper is organized in five sections. Section 1 introduces the reader to the basic notions and facts concerning median sets, free actions on median sets and median groups. In Section 2 we associate to an arbitrary free action of a group \(H\) on a nonempty set \(X\) a group \(\hat{H}\) with an underlying tree structure, together with a natural embedding of the \(H\)-set \(X\) into \(\hat{H}\). Section 3 is devoted to the proof of a more explicit version of Theorem 1 by providing a procedure for deformation of the underlying simplicial tree of \(\hat{H}\) introduced in Section 2 into suitable median group operations on \(\hat{H}\) which extend given median operations on the \(H\)-set \(X\). Then, in Section 4 we use Theorem 1 and the duality theory for median sets to prove Theorem
2. Finally, by iteration of the functorial construction provided by Theorem 2, we prove Theorem 3 in Section 5.

1 Preliminaries on median sets, free actions on median sets and median groups

1.1 Median sets

The notion of median set (algebra) (see Definition 1 from Introduction) appeared as a common generalization of trees and distributive lattices. We recall here some basic definitions and properties related to median sets. For proofs and further details we refer the reader to the papers [1], [2], [4], [8], [13], [19], [20], [22], [23].

The median sets form a category with naturally defined morphisms.

Let $X = (X, m)$ be a nonempty median set. To any element $a \in X$ we associate the binary operation $(x, y) \mapsto x \cap y := m(x, a, y)$. With respect to this operation, $X$ is a meet-semilattice with the induced partial order $x \subset y \iff m(x, a, y) = x$ and the least element $a$, while for all $x, y, z \in X, m(x, y, z)$ is the join with respect to $\subset$ of the triple $(x \cap y, y \cap z, z \cap x)$.

**Definition 1.1.** (1) By a **median subset** of $X$ we understand any subset $A$ of $X$ which is closed under the median operation $m$.

(2) A subset $A$ of $X$ is called **convex** if the following stronger condition is satisfied: for all $x, y, z \in X, m(x, y, z) \in A$ whenever $x, y \in A$.

The intersection of any family of convex subsets of the median set $X$ is convex too. Thus we may speak on the **convex closure of (or the convex subset generated by)** a subset $A \subseteq X$, and denote it by $[A]$. Notice that $[\emptyset] = \emptyset, [\{a\}] = \{a\}$ for $a \in X$, and $[\{a, b\}] = \{a, b\} := \{m(a, b, x) \mid x \in X\} = \{x \in X \mid m(a, b, x) = x\}$ for $a, b \in X$.

**Definition 1.2.** (1) By a **cell** of $X$ we mean a convex subset of the form $[a, b]$ with $a, b \in X$.

(2) Given a cell $C$ of $X$, any $a \in X$ for which there exists $b \in X$ such that $C = [a, b]$ is called an end of the cell $C$. The (nonempty) subset of all ends of a cell $C$ is denoted by $\partial C$ and is called the boundary of $C$.

The boundary $\partial C$ of a cell $C$ is a median subset of $C$, and there is a canonical automorphism $\neg$ of the median set $\partial C$ such that $C = [a, \neg a]$ and $\neg \neg a = a$ for all $a \in \partial C$. For any element $a \in \partial C$, the cell $C$ becomes a bounded distributive lattice with the partial order $\subset$, the meet $\cap$, the join $\vee$, the least element $a$, and the last element $\neg a$. The boundary $\partial C$ is identified with the boolean subalgebra of the distributive lattice $(C, \subset)$ consisting of those elements which have (unique) complements.

**Definition 1.3.** A median set $X$ is said to be **locally boolean** if $C = \partial C$ for all cells $C$ of $X$. 

In particular, any boolean algebra \((L; \sqcap, \sqcup, \neg, 0, 1)\) is a locally boolean median set with respect to the canonical median operation
\[
m(x, y, z) := (x \land y) \lor (y \land z) \lor (z \land x) = (x \lor y) \land (y \lor z) \land (z \lor x).
\]
For \(x, y, z \in L\), \([x, y] = [x \land y, x \lor y] = [m(x, y, z), m(x, y, \neg z)]\), in particular, \(L = [0, 1] = [x, \neg x]\) for all \(x \in L\).

**Remark 1.4.** Let \(X = (X, m)\) be a median set. Then the following assertions hold.

1. For \(a, b, c \in X\), \([a, b] \cap [a, c] = [a, b \land c] \land [b, c] \cap [a, b] = \{m(a, b, c)\}\), and \(c \in [a, b] \Longleftrightarrow [a, c] \cap [b, c] = \{c\}\).

2. For nonempty finite subsets \(A, B \subseteq X\), \([A] \cap [B]\) is either empty or the finitely generated convex subset \([\bigcap B | a \in A]\) = \([\bigcap A | b \in B]\), where \(\bigcap B\) denotes the meet of the finite set \(B\) with respect to the partial order \(\subseteq\). In particular, for \(a, b, c, d \in X\), \([a, b] \cap [c, d]\) is either empty or the cell \([a \cap b, a \cap d] = [c \cap d, c \cap d]\).

Among the convex subsets of a median set, we distinguish the prime ones, defined as follows.

**Definition 1.5.** A convex subset \(P\) of a median set \(X\) is said to be prime if its complement \(X \setminus P\) is also a convex subset of \(X\).

Thus the set \(\text{Spec} X\) of prime convex subsets of \(X\) is closed under the involution \(P \mapsto \neg P := X \setminus P\), and contains the empty set \(\emptyset\) as well as the whole \(X\). For any subset \(A\) of \(X\), set \(U(A) := \{P \in \text{Spec} X \mid P \cap A = \emptyset\}\), \(V(A) := \{P \in \text{Spec} X \mid A \subseteq P\}\), and \(U(a) := U(\{a\}), V(a) := V(\{a\})\) for \(a \in A\), whence \(U(A) = \bigcap_{a \in A} U(a), V(A) = \bigcap_{a \in A} V(a)\). The next result collects some basic properties of the space \(\text{Spec} X\). For a proof see [4] Theorems 5.2.1, 6.4.]

**Theorem 1.6.** \(1\) For \(A, B \subseteq X, V(A) \cap U(B) \neq \emptyset \iff [A] \cap [B] = \emptyset\); in particular, \([A] = \bigcap_{P \in V(A)} P\).

2. With respect to the topology defined by the basic open sets \(U(A)\) for \(A\) ranging over the finite subsets of \(X\), \(\text{Spec} X\) is an irreducible spectral space \(^3\) with the generic point \(\emptyset\) and the unique closed point \(X\).

3. The proper quasicompact open subsets of \(\text{Spec} X\) form a distributive lattice
\[
\mathcal{L}(X) := \bigcup_{i=1}^{n} U(A_i) \mid n \geq 1, \emptyset \neq A_i \subseteq X \text{ finite, for } i = 1, \ldots, n,
\]

\(^3\) A topological space \(S\) is said to be spectral (or coherent) if
i) \(S\) is sober, i.e. every irreducible nonempty closed subset of \(S\) is the closure of a unique point of \(S\), and
ii) the family of all quasicompact open subsets of \(S\) is closed under finite intersection (in particular, \(S\) itself is quasicompact) and forms a base for the topology of \(S\).

A map \(f : S' \to S\) between spectral spaces is called coherent if \(f^{-1}(U) \subseteq S'\) is a quasicompact open set provided \(U \subseteq S\) is a quasicompact open set. In particular, a coherent map is continuous.
closed under the negation operator

\[ \mathcal{U} \mapsto \neg \mathcal{U} := \{ P \in \text{Spec} \mathcal{X} \mid \neg P \notin \mathcal{U} \}, \]

while the embedding \( X \to \mathcal{L}(\mathcal{X}) \), \( x \mapsto U(x) \) identifies the median set \( \mathcal{X} \) to the invariant subset \( \{ \mathcal{U} \in \mathcal{L}(\mathcal{X}) \mid \neg \mathcal{U} = \mathcal{U} \} \), with the canonical median operation

\[ \mathfrak{m}(\mathcal{U}_1, \mathcal{U}_2, \mathcal{U}_3) := (\mathcal{U}_1 \cap \mathcal{U}_2) \cup (\mathcal{U}_2 \cap \mathcal{U}_3) \cup (\mathcal{U}_3 \cap \mathcal{U}_1) = (\mathcal{U}_1 \cup \mathcal{U}_2) \cap (\mathcal{U}_2 \cup \mathcal{U}_3) \cap (\mathcal{U}_3 \cup \mathcal{U}_1). \]

(4) The correspondence \( \mathcal{X} \mapsto \text{Spec} \mathcal{X} \) yields a duality between the category of median sets and a category of irreducible spectral spaces with a suitable additional structure.

(5) The correspondence \( \mathcal{X} \mapsto \mathcal{L}(\mathcal{X}) \) yields an equivalence between the category of median sets and the category of distributive lattices with negation \((L, \neg)\) which are generated (as lattices) by their invariant subsets \( \{ a \in L \mid \neg a = a \} \).

As a corollary we obtain a description of the median set \( \text{fms}(A) \) freely generated by an arbitrary set \( A \).

**Corollary 1.7.** (1) The restriction map \( \text{Spec} \text{fms}(A) \to \mathcal{P}(A), P \mapsto P \cap A \) is bijective, identifying the spectral space \( \text{Spec} \text{fms}(A) \) to the power set \( \mathcal{P}(A) \) with the basic open sets \( U(F) = \mathcal{P}(A \setminus F) \) for \( F \) ranging over the finite subsets of \( A \).

2 The elements of the distributive lattice \( \mathcal{L}(\text{fms}(A)) \) correspond bijectively to families \( (F_i)_{i=1}^n \), \( n \geq 1 \), where the \( F_i \)'s are incomparable nonempty finite subsets of \( A \); such a family \( (F_i)_{i=1}^n \) corresponds to the proper quasicompact open set

\[ \bigcup_{i=1}^n U(F_i) = \bigcup_{i=1}^n \mathcal{P}(A \setminus F_i). \]

(3) The negation operator sends a family \( (F_i)_{i=1}^n \) as above to the finite family of the subsets \( E \subseteq \bigcup_{i=1}^n F_i \) which are minimal with the property \( E \cap F_i \neq \emptyset \) for \( i = \overline{1,n} \).

(4) The elements of the median set \( \text{fms}(A) \) freely generated by the set \( A \) correspond bijectively to families \( (F_i)_{i=1}^n \), \( n \geq 1 \), where the \( F_i \)'s are incomparable nonempty finite subsets of \( A \) satisfying

(i) \( F_i \cap F_j \neq \emptyset \) for \( 1 \leq i, j \leq n \), and

---

4) More precisely, according to [4], the objects of the dual category of the category of median sets are the systems \((S,0,1,\neg)\), where \( S \) is an irreducible spectral space with generic point \( 0 \), \( 1 \) is the unique closed point of \( S \), and \( \neg : S \to S \) is an involution satisfying the following conditions.

(1) For every quasicompact open set \( U \subseteq S \), the set \( \neg U := \{ s \in S \mid \neg s \notin U \} \) is quasicompact open.

(2) The quasicompact open sets \( U \subseteq S \) satisfying \( \neg U = U \) generate the topology of \( S \).

It follows that \( \neg 0 = 1 \).

The morphisms \( f : (S,0,1,\neg) \to (S',0',1',\neg') \) are the coherent maps \( f : S \to S' \) satisfying \( f(0) = 0' \) and \( f \circ \neg = \neg' \circ f \), whence \( f(1) = 1' \).
(ii) for each subset \( E \subseteq \bigcup_{i=1}^{n} F_i \) such that \( E \cap F_i \neq \emptyset \) for \( i = 1, n \), there is \( 1 \leq j \leq n \) such that \( F_j \subseteq E \).

In particular, the finitely generated median sets are finite, and any median set is a direct limit of finite median sets.

**Definition 1.8.** A median set \( X \) is said to be *locally linear* if the following equivalent conditions are satisfied.

1. Every cell \( C \) of \( X \) has at most two ends, i.e. \( |\partial C| \in \{1, 2\} \).
2. For all \( a, b \in X \), the cell \( [a, b] \) is the set-theoretic union of the cells \( [a, c] \) and \( [b, c] \) provided \( c \in [a, b] \).
3. For \( a, b \in X \), the partial order \( \subset \) restricted to the cell \( [a, b] \) is total (linear) with the least element \( a \) and the last element \( b \).
4. For \( P, Q \in \text{Spec} X \) such that \( P \cap Q \neq \emptyset \) and \( P \cup Q \neq X \), either \( P \subseteq Q \) or \( Q \subseteq P \).

**Remark 1.9.** The locally linear median sets are strongly related with order-trees. Recall that an *order-tree* is a poset \( T = (T, \leq) \) satisfying

(i) For every pair \( (x, y) \) of elements in \( T \), there exists the meet \( x \wedge y \), and
(ii) \( x \leq z \) and \( y \leq z \) imply either \( x \leq y \) or \( y \leq x \).

Since for any triple \( (x, y, z) \) of elements in an order-tree \( T \), the set \( \{x \wedge y, y \wedge z, z \wedge x\} \) has at most two distinct elements, it follows that \( T \) has a natural structure of locally linear median set with

\[
m(x, y, z) := (x \wedge y) \vee (y \wedge z) \vee (z \wedge x) \in \{x \wedge y, y \wedge z, z \wedge x\},
\]

and \( [x, y] = [x \wedge y, x] \cup [x \wedge y, y] \).

The next notion will be very useful in the present paper.

**Definition 1.10.** By a *folding* of a median set \( X = (X, m) \) we mean a map \( \varphi : X \rightarrow X \) satisfying \( \varphi(m(x, y, z)) = m(\varphi(x), y, \varphi(z)) \) for all \( x, y, z \in X \).

One checks easily that a map \( \varphi : X \rightarrow X \) is a folding if and only if \( \varphi \) is an idempotent endomorphism of the median set \( X \) and the image \( \varphi(X) \) is a convex subset of \( X \). In addition, according to \([2, \text{Proposition 7.3}]\), the map \( \varphi \mapsto \varphi(X) \) maps bijectively the foldings of \( X \) onto the nonempty convex subsets \( A \) of \( X \) satisfying the following equivalent conditions.

i) \( A \) is retractible, i.e. there is a (unique) median set retract \( p : X \rightarrow A \) of the median set embedding \( A \hookrightarrow X \);
ii) For some (for all) \( a \in A \), \( A \cap [a, x] \) is a cell for all \( x \in X \);
iii) For all \( x \in X \), the meet \( \bigcap_x A \) with respect to the partial order \( \subseteq \) exists and belongs to \( A \).

In particular, to any nonempty finite subset \( A \) of a median set \( X = (X, m) \), we associate the folding \( \varphi_A \) defined by \( \varphi_A(x) = \bigcap_x A \), the meet with respect to the partial
order \( \subset \) of the finite set \( A \), whence \( \bigcap_{a \in A} [x, a] = [x, \varphi_A(x)] \) for all \( x \in X \), and \( \varphi_A(X) = [A] \).

**Definition 1.11.** A median set \( X = (X, m) \) is said to be simplicial (or discrete) if every cell of \( X \) has finitely many elements.

To a simplicial median set \( X \) one assigns an integer-valued "distance" function \( d : X \times X \to \mathbb{N} \), where for \( x, y \in X \), \( d(x, y) \) is the length of some (of any) maximal chain in the finite distributive lattice \( ([x, y], \subset_x) \). With respect to \( d \), \( X \) becomes a Z-metric space such that for all \( x, y \in X \), \([x, y] = \{ z \in X | d(x, z) + d(z, y) = d(x, y) \} \), and the map \( [x, y] \to [0, d(x, y)] \), \( z \mapsto d(x, z) \), induced by \( d \), is onto. In particular, \( d(x, y) = d(u, v) \) whenever \( [x, y] = [u, v] \), so we may speak on the "diameter" of any cell of \( X \). Notice also that for \( x, y, z \in X \), \( d(x, y) + d(x, z) - d(y, z) \).

An equivalent graph theoretic description of simplicial median sets is given by [8, Proposition 7.3]. In particular, the customary simplicial trees (i.e., acyclic connected graphs) are identified with those simplicial median sets \( X \) which are locally linear, i.e., for all \( x, y \in X \), the map \( [x, y] \to [0, d(x, y)] \) induced by \( d \) is bijective.

Notice also that in any simplicial median set, the nonempty convex subsets are retractible, and the finitely generated convex subsets are finite.

### 1.2 Groups acting freely on median sets

By a tree-free group we mean a group having an action on a \( \Lambda \)-tree, for some totally ordered abelian group \( \Lambda \), which is free and without inversions. This means that every non-identity element acts as a hyperbolic isometry (see [16, Chapter 3]). As any \( \Lambda \)-tree, where \( \Lambda \) is a totally ordered abelian group, has an underlying structure of locally linear median set, the tree-free groups form a remarkable subclass of the larger class \( \text{MSFG} \) consisting of the groups having a free action on some nonempty median set.

**Lemma 1.12.** \( \text{MSFG} \) is a quasivariety of groups, i.e. it is closed under isomorphisms, subgroups, and reduced products, and it contains the trivial group \( 1 \) (i.e. \( \text{MSFG} \neq \emptyset \)).

**Proof.** We have only to show that the class \( \text{MSFG} \) is closed under reduced products. Let \( I \) be a nonempty set, \( \mathcal{F} \) a filter on \( I \), and \((G_i)_{i \in I} \) a family of members of \( \text{MSFG} \). For each \( i \in I \), let \( G_i \times X_i \to X_i \) be a free action on a nonempty median set \( X_i \). Using the filter \( \mathcal{F} \), we define the normal subgroup \( N \) of the product \( \prod_{i \in I} G_i \) and the congruence \( \equiv \) on the median set product \( \prod_{i \in I} X_i \) by

\[
N := \{(g_i)_{i \in I} \in \prod_{i \in I} G_i \mid \{i \in I \mid g_i = 1_i \} \in \mathcal{F}\},
\]

\[
x \equiv y \iff \{i \in I \mid x_i = y_i \} \in \mathcal{F}, \text{ for } x = (x_i)_{i \in I}, y = (y_i)_{i \in I} \in \prod_{i \in I} X_i.
\]

One checks easily that the canonical free action \( (\prod_{i \in I} G_i) \times (\prod_{i \in I} X_i) \to \prod_{i \in I} X_i \) induces a free action of the reduced product \( G := (\prod_{i \in I} G_i)/N \) on the quotient median set \( X := (\prod_{i \in I} X_i)/\equiv \), as desired. \( \square \)
Lemma 1.13. As a full subcategory of the category $G$ of groups, $\text{MSFG}$ is reflective. The reflector, the left adjoint of the embedding $\text{MSFG} \rightarrow G$, sends a group $G$ to its quotient $G/N$, where $N$ is the smallest normal subgroup such that $G/N$ belongs to $\text{MSFG}$.

Proof. Given a group $G$, we denote by $N$ the set of those normal subgroups $U$ of $G$ for which the quotient $G/U$ belongs to $\text{MSFG}$. The set $N$ is nonempty since $G \in N$.

Set $N := \bigcap_{U \in N} U$, the kernel of the canonical morphism $G \rightarrow \prod_{U \in N} G/U$. As $\text{MSFG}$ is closed under products and subgroups, it follows that $G/N$ belongs to $\text{MSFG}$, whence $N$ is the least member of the poset $N$ with respect to inclusion. The required adjunction property is immediate. \hfill \Box

As a quasivariety, the class of groups $\text{MSFG}$ is axiomatized by quasi-identities (see [14, Theorem 2.25], [18, Theorem 9.4.7]). These quasi-identities turn out to be quite simple according to the next lemma.

Lemma 1.14. Let $G$ be a group. Then the following assertions are equivalent.

1. $G$ belongs to $\text{MSFG}$.

2. The canonical action of $G$ on the median set $\text{fms}(G)$ freely generated by the underlying set of $G$ is free.

3. For all $g \in G$, either $g$ is of infinite order or the order of $g$ is a power of 2.

Proof. (1) $\Rightarrow$ (3). Assume that $G$ acts freely on the nonempty median set $X$, and assume that there is $g \in G$ of prime order $p \neq 2$, say $p = 2k + 1, k \geq 1$. We have to get a contradiction. We may assume without loss that $G$ is cyclic of order $p$, generated by $g$. Fix an element $x \in X$, so $Gx$, the $G$-orbit of $x$, has cardinality $p$. We denote by $F$ the (finite) set of all subsets $F \subseteq Gx$ of cardinality $|F| = k + 1$. For any $F \in \mathcal{F}$, the set $U(F) = \{P \in \text{Spec} X | P \cap F = \emptyset \}$ is a basic quasicompact open subset of the spectral space $\text{Spec} X$ of prime convex subsets of $X$ (cf. Theorem 1.6.(2)). Consequently, the union $U := \bigcup_{F \in \mathcal{F}} U(F) = \{P \in \text{Spec} X | |P \cap Gx| \leq k \} \in L(X)$ is a proper quasicompact open subset of $\text{Spec} X$. Moreover $U = \neg U = \{P \in \text{Spec} X | X \setminus P \notin U \}$, therefore, according to Theorem 1.6.(3), there is an unique element $y \in X$ such that $U = U(y) = \{P \in \text{Spec} X | y \notin P \}$. Equivalently, by Theorem 1.6.(1), $y$ is the unique common element of the convex closure $[F] = \bigcap_{F \subseteq P \in \text{Spec} X} P$ of $F$ in the median set $X$ for $F$ ranging over $\mathcal{F}$. Since $g$ acts as a permutation on $\mathcal{F}$, we deduce that $gy = y$, contrary to the assumption that $G$ acts freely on $X$.

(3) $\Rightarrow$ (2). Assume that $G$ satisfies (3) and there is $g \in G \setminus \{1\}$ such that $gx = x$ for some $x \in \text{fms}(G)$. We have to obtain a contradiction. By Corollary 1.7.(4), the element $x = gx \in \text{fms}(G)$ is uniquely determined by a suitable finite family $\mathcal{F} = (F_i)_{i=1}^n, n \geq 1$, of incomparable nonempty finite subsets of $G$, whence $gF_i = \{gh | h \in F_i \} = F_{\sigma(i)}, i = 1, n$, for some permutation $\sigma$ of the finite set $\{1, \ldots, n\}$. Consequently,
If $g$ has finite order, so we may assume without loss that $g$ has order 2. Set $F := \bigcup_{i=1}^{n} F_i$.

As $gF = \{gh \mid h \in F\} = F$, there is $E \subseteq F$ such that $F$ is the disjoint union of its subsets $E$ and $gE$, in particular, $|F| = 2k$ with $k = |E| = |gE| \geq 1$. We distinguish the following two cases.

(i) $E \cap F_i = \emptyset$ for some $1 \leq i \leq n$. Then $F_i \subseteq gE$, whence $F_{\sigma(i)} = gF_i \subseteq g^2E = E$, therefore $F_i \cap F_{\sigma(i)} = \emptyset$, contrary to the condition (i) of Corollary 1.7.(4) satisfied by the family $\mathcal{F}$.

(ii) $E \cap F_i \neq \emptyset$ for all $1 \leq i \leq n$. Then, by condition (ii) of Corollary 1.7.(4) satisfied by the family $\mathcal{F}$, there is $1 \leq j \leq n$ such that $F_j \subseteq E$, whence $F_{\sigma(j)} = gF_j \subseteq gE$, so $F_j \cap F_{\sigma(j)} = \emptyset$, again a contradiction.

Finally notice that the implication $(2) \implies (1)$ is trivial. \hfill \Box

**Corollary 1.15.** The quasivariety of groups $\text{MSFG}$ is axiomatized by the quasi-identities

$$x^p = 1 \rightarrow x = 1$$

for $p$ ranging over the set of odd prime numbers.

### 1.3 Median groups

We recall here some basic definitions and properties related to median groups. For proofs and further details we refer the reader to the papers [3], [6], [10].

**Definition 1.16.** (1) Let $G$ be a group. By a median group operation on $G$ we understand a ternary operation $m : G^3 \rightarrow G$ satisfying

(i) $(G, m)$ is a median set, and

(ii) $um(x, y, z) = m(ux, uy, uz)$ for all $u, x, y, z \in G$.

(2) By a median group we understand a group $G$ together with a median group operation $m$ on $G$.

(3) By a formally-median group we mean a group $G$ satisfying the following equivalent conditions.

(i) There exists a median group operation on $G$.

(ii) $G$ acts freely and transitively on some nonempty median set.

(iii) There exists a $G$-equivariant retract $\varphi : \text{fms}(G) \rightarrow G$ of the canonical $G$-equivariant embedding of $G$ into the median set $(\text{fms}(G), m)$ freely generated by the set $G$ such that $\varphi(m(x, y, z)) = \varphi(m(\varphi(x), y, z))$ for all $x, y, z \in \text{fms}(G)$.

Let $G = (G, m)$ be a median group. Taking the neutral element 1 as a basepoint of the underlying median set of $G$, we get the meet-semilattice operation $x \cap y = m(x, 1, y)$
with the induced partial order \( \subset \). Thus \( 1 \subset x \) for all \( x \in G \), and \( x \subset y \iff x \in [1, y] \). Notice also that \( z \in [x, y] \iff x^{-1}z \subset x^{-1}y \), and

\[
m(x, y, z) = x(x^{-1}y \cap x^{-1}z) = y(y^{-1}x \cap y^{-1}z) = z(z^{-1}x \cap z^{-1}y)
\]

for all \( x, y, z \in G \). In particular, for \( x, y \in G \), \( x \cap y \) is the unique element \( z \in G \) satisfying \( z \subset x, z \subset y \) and \( x^{-1}z \subset x^{-1}y \).

The next statement furnishes a useful order theoretic description of median groups.

**Proposition 1.17.** (cf. [6, Proposition 2.2.1.]) Let \( G \) be a group. Then the map sending a ternary operation \( m : G^3 \to G \) to the binary operation \( \cap \), defined by \( x \cap y := m(x, 1, y) \), maps bijectively the median group operations on \( G \) onto the binary operations \( \cap \) on \( G \) satisfying

1. \((G, \cap)\) is a meet-semilattice; let \( x \subset y \iff x \cap y = x \) be the induced partial order,
2. \( 1 \subset x \) for all \( x \in G \),
3. \( x \subset y, y \subset z \Rightarrow z^{-1}y \subset z^{-1}x \), and
4. \( x^{-1}(x \cap y) \subset x^{-1}y \) for all \( x, y \in G \).

In both the signatures \((1, -1, \cdot, m)\) and \((1, -1, \cdot, \cap)\) of type \((0, 1, 2, 3)\) and \((0, 1, 2, 2)\) respectively, the median groups form a variety. In particular, the class of median groups is closed under arbitrary products, with group and median operations defined component-wise.

**Definition 1.18.** A median group is said to be **locally linear** (simplicial) if its underlying median set is locally linear (simplicial).

**Corollary 1.19.** (cf. [6, Corollary 2.2.2.]) Let \( G \) be a group. Then the map sending a ternary operation \( m : G^3 \to G \) to the binary relation \( x \subset y \iff m(x, 1, y) = x \) maps bijectively the locally linear median group operations on \( G \) onto the partial orders \( \subset \) on \( G \) satisfying

1. \( 1 \subset x \) for all \( x \in G \),
2. \( x \subset y, y \subset z \Rightarrow z^{-1}y \subset z^{-1}x \),
3. for all \( x, y \in G \) there exists \( z \in G \) such that \( z \subset x, z \subset y \) and \( x^{-1}z \subset x^{-1}y \), and
4. \( x \subset z, y \subset z \Rightarrow \) either \( x \subset y \) or \( y \subset x \).

In particular, if \((G, \leq)\) is a left-ordered group\(^5\), then the total order \( \leq \) determines a locally linear median group operation \( m \) on \( G \) whose associated partial order \( \subset \) is given by \( u \subset v \iff \) either \( 1 \leq u \leq v \) or \( v \leq u \leq 1 \). In other words, the median operation \( m \) is induced by the betweenness relation associated to the total order \( \leq \). Notice that there exist groups \( G \) together with total orders \( \leq \) such that \((G, \leq)\) is not left-ordered,

---

\(^5\) A left-ordered group is a group \( G \), together with a total order \( \leq \) on \( G \) such that \( u \leq v \implies gu \leq gv \) for all \( g, u, v \in G \). A group \( G \) is left-orderable if \((G, \leq)\) is left-ordered for some total order \( \leq \) on \( G \).
but the median operation induced by the betweenness relation associated to the total order \( \leq \) is compatible with the left multiplication (see Remark 1.21.(2)). In any case, possible connections with the much more studied class of left-orderable groups could be fruitful.

**Corollary 1.20.** The necessary and sufficient condition for a median group \( G = (G,m) \) to be simplicial is that for all \( x \in G \), the cell \( [1,x] = \{ y \in G \mid y \subseteq x \} \) has finitely many elements.

**Remark 1.21.** According to Corollary 1.15., the quasivariety \( MSFG \) of groups acting freely on median sets is described by very simple quasi-identities. By contrast, the proper subclass of \( MSFG \) consisting of the formally-median groups is not enough investigated. Some particular classes of such groups are studied in [3], [6], [7], [10]. For convenience of the reader we discuss here only the simplest case of formally-median cyclic groups.

1. Though all cyclic groups of order \( 2^n, n \in \mathbb{N} \), belong to \( MSFG \), only three of them with \( n = 0, 1, 2 \) are formally-median groups. The corresponding median group operations are uniquely determined: the point, the segment \( [1, \sigma] \), \( \sigma^2 = 1 \), and the square \( [1, \sigma^2] = [\sigma, \sigma^3], \sigma^4 = 1 \), respectively.

2. The infinite cyclic group \( (\mathbb{Z},+) \) has a canonical structure of simplicial and locally linear median group with respect to the median group operation \( m_0 \) associated to the usual simplicial tree on \( \mathbb{Z} \), induced by the natural order: \( m_0(x,y,z) = y \iff \) either \( x \leq y \leq z \) or \( z \leq y \leq x \). However there are still two distinct median group operations \( m_1 \) and \( m_{-1} \) on \( (\mathbb{Z},+) \), which are both locally linear but not simplicial, related each to other through the unique nonidentical automorphism \( n \mapsto -n \) of the group \( (\mathbb{Z},+) \):

\[
m_{-1}(x,y,z) = -m_1(-x,-y,-z) \quad \text{for} \ x,y,z \in \mathbb{Z}.
\]

Thus there are only two (up to isomorphism) median groups with the underlying group \( (\mathbb{Z},+) \). To prove the assertion above and describe explicitly the median group operation \( m_1 \), introduced in [10, Remarks 3.2.(3)], we proceed as follows. Let \( m \) be a median group operation on \( (\mathbb{Z},+) \), with the associated meet-semilattice operation \( \cap \) and partial order \( \subseteq \) (cf. Proposition 1.17.)

Let \( x,y \in \mathbb{Z} \) be such that \( 0 < x < y \), and let \( z := m(0,x,y) = x \cap y \). Assuming that \( y < z \) and using the fact that the translation \( n \mapsto n + 1 \) is an automorphism of the median set \( (\mathbb{Z},m) \), we deduce that \( \mathbb{N} \) is contained in the median subset of \( (\mathbb{Z},m) \) generated by the finite set \( \{0,1,\ldots,z\} \), i.e. a contradiction. Similarly, assuming that \( z < 0 \) and using the translation \( n \mapsto n - 1 \), we deduce that \( \mathbb{Z}_{\leq y} \) is contained in the median subset generated by the finite set \( \{z,z+1,\ldots,y\} \), again a contradiction. Thus the following implication holds

\[
(*) \quad 0 < x < y \implies 0 \leq x \cap y \leq y.
\]

In particular, we get \( 1 \cap 2 = m(0,1,2) \in \{0,1,2\} \). We distinguish the following three cases.

1. \( 1 \cap 2 = 1 \), i.e. \( 1 \subset 2 \). To obtain \( m = m_0 \), it suffices by Proposition 1.17. to show that \( n \subset n + 1 \) for all \( n \geq 1 \). As \( 1 \subset 2 \) by hypothesis, assuming by induction that
$k \subset k + 1$ for $1 \leq k < n, n \geq 2$, we have to show that $s := m(0, n, n + 1) = n$. By $(\ast)$, $0 \leq s \leq n + 1$. Assuming that $s \neq n$, there are three possibilities.

(a) $1 \leq s \leq n - 1$, whence $s - 1 \subset n - 1 \subset n$ by the induction hypothesis. On the other hand, $s \in [n, n + 1]$, therefore $s - 1 \in [n - 1, n]$, so $n - 1 \subset s - 1 \subset n$. Consequently, $s - 1 = n - 1$, contrary to the assumption $s \leq n - 1$.

(b) $s = 0$, i.e. $0 \in [n, n + 1]$, and hence $n - 1 \in [0, n] \subset [n, n + 1]$. As $1 \in [0, 2] \implies n \in [n - 1, n + 1]$, we deduce that $n - 1 = n$, i.e. a contradiction.

(c) $s = n + 1$, i.e. $n + 1 \in [0, n]$, therefore $[n - 1, n + 1] \subset [0, n]$. Setting $t := m(0, n - 1, n + 1)$, we obtain by Remark 1.4.(2)

$$[n - 1, n + 1] = [n - 1, n + 1] \cap [0, n] = [t, m(n, n - 1, n + 1)] = [t, n],$$

whence $t \notin \{n - 1, n + 1\}$, and hence $0 \leq t \leq n - 2$ by $(\ast)$. Assuming that $t \neq 0$, it follows by the induction hypothesis that $t - 1 \subset n - 2 \subset n - 1 \subset n$. Since $[n - 1, n + 1] = [t, n] \implies [n - 2, n] = [t - 1, n - 1]$ (by translation with $-1$), we deduce that $n - 1 = n$, i.e. a contradiction. Consequently, $t = 0$, and hence $1 \in [0, n] = [n - 1, n + 1]$; whence $0 \in [n - 2, n]$ (by translation with $-1$). As $n - 2 \subset n$, it follows that $n - 2 = 0$, i.e. $[0, 2] = [1, 3]$, whence $[0, 2] = [2, 4]$ (by translation with 1), therefore $0 = 4$, i.e. again a contradiction.

Since in all three possible cases (a), (b), (c) we obtain a contradiction, we deduce that $n \subset n + 1$ for all $n \in \mathbb{N}$, and hence $m = m_0$ as desired.

(ii) $1 \cap 2 = 2$, i.e. $2 \in [0, 1]$, and hence $1 \in [0, -1]$ (by translation with $-1$), whence $2 \subset 1 \subset 1 - 1$. Applying successively the translation $k \mapsto k + 2$, it follows that $2n \subset 2n + 2 \subset 2n + 1 \subset 2n - 1$ for $n \in \mathbb{N}$. Consequently, the median group operation $m := m_1$ is uniquely determined by the betweenness relation induced by the total order $\prec$ (or its opposite) on $\mathbb{Z}$, defined by $x \prec y$ if and only if one of the following assertions hold

(a) $x, y$ are even and $x \leq y$;

(b) $x, y$ are odd and $y \leq x$;

(c) $x$ is even and $y$ is odd.

(iii) $1 \cap 2 = 0$, i.e. $0 \in [1, 2]$, whence $-1 \in [0, 1]$ (by translation with $-1$), i.e. $-1 \subset 1$. It follows that the median group operation $m := m_{-1}$ is the conjugate of $m_1$ by the group automorphism $n \mapsto -n$, and hence it is uniquely determined by the betweenness relation induced by the total order $\prec'$ (or its opposite) on $\mathbb{Z}$ obtained from $\prec$ by replacing (c) with

(c') $x$ is odd and $y$ is even.

Notice that though the total orders $\prec$ and $\prec'$ are not compatible with the group operation on $\mathbb{Z}$, the induced median operations $m_1$ and $m_{-1}$ are so.
Notice also that $2\mathbb{Z}$ is a median subgroup of $(\mathbb{Z}, m_i), i = 0, 1, -1, \text{ and } m_i|_{2\mathbb{Z}} = m_0|_{2\mathbb{Z}}, i = 1, -1$. However, by contrast with the median group $(\mathbb{Z}, m_0)$ which has no proper convex subgroups, and hence no proper quotients, $2\mathbb{Z}$ is the unique proper convex subgroup of $(\mathbb{Z}, m_1) \cong (\mathbb{Z}, m_{-1})$, inducing the surjective morphism of median groups $(\mathbb{Z}, m_1) \cong (\mathbb{Z}, m_{-1}) \rightarrow \mathbb{Z}/2$, whose kernel is isomorphic to the median group $(\mathbb{Z}, m_0)$. In other words, the isomorphic median groups $(\mathbb{Z}, m_1)$ and $(\mathbb{Z}, m_{-1})$ are extensions of the median group $\mathbb{Z}/2$ by the median group $(\mathbb{Z}, m_0)$.

(3) The construction above has a nice interpretation in terms of the nonstandard arithmetic. Let $^*\mathbb{Z}$ be an enlargement of $\mathbb{Z}$. For our purposes it suffices to take $^*\mathbb{Z}$ an ultrapower of $\mathbb{Z}$ relative to a nonprincipal ultrafilter on $\mathbb{N}$. We denote by $^*m_i$ the median group operation on $^*\mathbb{Z}$ which extends the median group operation $m_i$, $i = 0, 1, -1$. Let $T_i := \{ t \in ^*\mathbb{Z} | \forall x, y \in \mathbb{Z}, ^*m_i(t,x,y) \in \mathbb{Z} \}$. $T_i$ is the maximal median subset of $(^*\mathbb{Z}, ^*m_i)$ lying over $\mathbb{Z}$ with the property that $\mathbb{Z}$ is convex in $(T_i, ^*m_i|_{T_i})$. Since $(\mathbb{Z}, m_0)$ is simplicial, it follows that $T_0 = ^*\mathbb{Z}$, while

$$T_1 = \left\{-2t \mid t \in ^*\mathbb{N} \setminus \mathbb{N} \right\} \bigcup \mathbb{Z} \bigcup \{ -2t + 1 \mid t \in ^*\mathbb{N} \setminus \mathbb{N} \},$$

$$T_{-1} = \{ 2t + 1 \mid t \in ^*\mathbb{N} \setminus \mathbb{N} \} \bigcup \mathbb{Z} \bigcup \{ 2t \mid t \in ^*\mathbb{N} \setminus \mathbb{N} \}$$

are proper median submonoids of the median group $(^*\mathbb{Z}, +, ^*m_i)$ for $i = 1, -1$ respectively, containing $\mathbb{Z}$ as the maximal (convex) subgroup.

Let us consider the congruence $\equiv_i$ on the median set $(T_i, ^*m_i|_{T_i})$, defined by

$$t \equiv_i t' \iff \forall x, y \in \mathbb{Z}, ^*m_i(t,x,y) = ^*m_i(t',x,y).$$

According to [2] A.1.1, the quotient median set $T_i/\equiv_i$ is isomorphic to the median set $\text{Dir}(\mathbb{Z}, m_i)$ of the directions on the median set $(\mathbb{Z}, m_i)$, containing $\mathbb{Z}$ as the external subset of internal directions. It follows that $\text{Dir}(\mathbb{Z}, m_i) = [D_i, D_i'] = \{ D_i \cup \mathbb{Z} \cup \{ D_i' \} \}$, where the external directions $D_i, D_i'$ are the equivalence classes $\{ -t \mid t \in ^*\mathbb{N} \setminus \mathbb{N} \}, \{ t \mid t \in ^*\mathbb{N} \setminus \mathbb{N} \}$ for $i = 0$, $\{ -2t \mid t \in ^*\mathbb{N} \setminus \mathbb{N} \}, \{ -2t + 1 \mid t \in ^*\mathbb{N} \setminus \mathbb{N} \}$ for $i = 1$, and $\{ 2t + 1 \mid t \in ^*\mathbb{N} \setminus \mathbb{N} \}, \{ 2t \mid t \in ^*\mathbb{N} \setminus \mathbb{N} \}$ for $i = -1$ respectively. The induced total order on $\mathbb{Z}$ from $D_i$ to $D_i'$ is $\leq$ for $i = 0$, $<$ for $i = 1$, and $\prec$ for $i = -1$. The canonical free action of $\mathbb{Z}$ on $T_i$, $(n, t) \in \mathbb{Z} \times T_i \mapsto n + t \in T_i$ induces an action on $\text{Dir}(\mathbb{Z}, m_i) \cong T_i/\equiv_i$ which is obviously free and transitive on the set $\mathbb{Z}$ of internal directions, identical on the external directions $D_0, D_0'$, and acting as $\mathbb{Z}/2$ on the pair of external directions $(D_i, D_i')$ for $i = 1, -1$.

We end this preliminary section with an useful lemma relating free actions on median sets and median groups.

**Lemma 1.22.** Let $G$ be a group, $H$ a subgroup of $G$, and $X \subseteq G$ a set of generators of $G$ such that $H \subseteq X$, and $HX = X$, whence $H \times X \rightarrow X, (h, x) \mapsto hx$ is a free action of $H$ on the nonempty set $X$, and the embedding $\iota : X \rightarrow G$ is $H$-equivariant. Let $\varphi : G \rightarrow X$ be a $H$-equivariant retract of $\iota$.

We denote by $M(X)$ the set of the median operations $m : X^3 \rightarrow X$ which are compatible with the action of $H$, i.e. $m(hx, hy, hz) = hm(x, y, z)$ for $h \in H, x, y, z \in X$. 

On the other hand, we denote by $\mathcal{M}(G, \varphi)$ the set of those median group operations $\hat{m} : G^3 \to G$ for which the map $\varphi$ is a folding, so $X$ is a retractible convex subset of $(G, \hat{m})$ with associated folding $\varphi$.

Then the restriction map $\mathcal{M}(G, \varphi) \to \mathcal{M}(X)$ is injective.

Proof. Let $I \subseteq X$ be a system of representatives of the $H$-orbits. Assume that $1 \in I$, and set $I' := I \setminus \{1\}$. Thus the disjoint union $(H \setminus \{1\}) \sqcup I'$ generates the group $G$.

Let $\hat{m} \in \mathcal{M}(G, \varphi)$, and $m \in \mathcal{M}(X)$ be its restriction. To prove that $\hat{m}$ is the unique prolongation of $m$, it suffices to show by duality (cf. Theorem 1.6.(4)) that $\text{Spec}(G, \hat{m})$ is uniquely determined by $\text{Spec}(X, m)$ and $\varphi$.

The $H$-equivariant morphisms of median sets $\iota : (X, m) \to (G, \hat{m})$ and $\varphi : (G, \hat{m}) \to (X, m)$ satisfying $\varphi \circ \iota = 1_X$ induce by duality the morphisms of spectral spaces

$$\text{Spec}(G, \hat{m}) \to \text{Spec}(X, m), P \mapsto P \cap X, \text{Spec}(X, m) \to \text{Spec}(G, \hat{m}), p \mapsto \varphi^{-1}(p)$$

such that $\varphi^{-1}(p) \cap X = p$ for all $p \in \text{Spec}(X, m)$.

As $\hat{m}$ is a median group operation, $G$ acts from the right on $\text{Spec}(G, \hat{m}), (P, g) \mapsto P^g := g^{-1}P$, while $H$ acts from the right on $\text{Spec}(X, m), (p, h) \mapsto p^h := h^{-1}p$, and the induced morphisms of spectral spaces are $H$-equivariant.

Let $\mathcal{S} := \{\varphi^{-1}(p)^g = g^{-1}\varphi^{-1}(p) \mid p \in \text{Spec}(X, m), g \in G\}$. Notice that $\emptyset, G \in \mathcal{S}$, and $P \in \mathcal{S} \implies G \cap P \in \mathcal{S}$. The inclusion $\mathcal{S} \subseteq \text{Spec}(G, \hat{m})$ is obvious, so it remains to prove the opposite inclusion. Let $P \in \text{Spec}(G, \hat{m}) \setminus \{\emptyset, G\}$. We distinguish the following three cases.

1. $p := P \cap X \neq \emptyset, X$. Then $P = \varphi^{-1}(p) \in \mathcal{S}$. Indeed, assuming the contrary, say $P \not\subseteq \varphi^{-1}(p)$, let $g \in P$ be such that $\varphi(g) \not\in p$. As $p \neq \emptyset$ by assumption, choose some $x \in p \subseteq P$. Since $\varphi$ is a folding of the median set $(G, \hat{m})$ with $\varphi(G) = X$, and $P$ is convex, we deduce that $\varphi(g) \in [x, g] \cap X \subseteq P \cap X = p$, i.e. a contradiction. The case $\varphi^{-1}(p) \not\subseteq P$ follows similarly by replacing $P$ with $G \setminus P$.

2. $X \subseteq P$. As $P \neq G$, choose an element $g \in G \setminus P$ of minimal length $l(g)$ over the alphabet $J := (H \setminus \{1\}) \cup I'^{\pm 1}$. In particular $g \neq 1$, i.e. $l(g) \geq 1$, since $1 \in X \subseteq P$ by assumption. Let $g = gt$ be a reduced word representing $g$, with $t \in J$. Notice that $g' = g^{-1}t \in P$ since $l(g') < l(g)$. There are two possibilities.

   (i) $t \in (H \setminus \{1\}) \cup I'^{-1}$. Then $t^{-1} \in g^{-1}P \cap X$, while $1 \in X \setminus g^{-1}P$. Consequently, $p := g^{-1}P \cap X \in \text{Spec}(X, m) \setminus \{\emptyset, X\}$, therefore $P = g\varphi^{-1}(p) \in \mathcal{S}$ by (1).

   (ii) $t \in I'$. Then $t = g^{-1}g \in X \setminus g^{-1}P$ and $1 = g'g' \in X \cap g^{-1}P$, whence $p := X \cap g^{-1}P \in \text{Spec}(X, m) \setminus \{\emptyset, X\}$, and hence $P = g'\varphi^{-1}(p) \in \mathcal{S}$ by (1) again.

3. $P \cap X = \emptyset$. Then $G \setminus P \in \mathcal{S}$ by (2), whence $P \in \mathcal{S}$ as desired. \hspace{1cm} \Box

In particular, taking $H = 1$, we obtain

**Corollary 1.23.** Let $G$ be a group, $X \subseteq G$ a set of generators with $1 \in X$, and $\varphi : G \to X$ a surjective map such that $\varphi(x) = x$ for all $x \in X$.

We denote by $\mathcal{M}(X)$ the set of median operations on $X$, and by $\mathcal{M}(G, \varphi)$ the set of median group operations on $G$ for which $X$ is a retractible convex subset with associated folding $\varphi$.

Then the restriction map $\mathcal{M}(G, \varphi) \to \mathcal{M}(X)$ is injective.
With the notation from Corollary 1.23., call the surjective map \( \varphi : G \to X \) admissible if \( \mathcal{M}(G, \varphi) \neq \emptyset \). Let us give some simple examples of admissible maps.

**Examples 1.24.**

1. For \( G = \langle g \mid g^4 = 1 \rangle \cong \mathbb{Z}/4, X = \{1, g\} \), the map \( \varphi : G \to X \), with \( \varphi(g^2) = \varphi(g) = g, \varphi(g^3) = \varphi(1) = 1 \), is the unique admissible map, and \( \mathcal{M}(G, \varphi) \) consists of the unique median group operation on \( G \) - the square with the pairs of opposite vertices \((1, g^2)\) and \((g, g^3)\), so the restriction map \( \mathcal{M}(G, \varphi) \to \mathcal{M}(X) \) is obviously bijective.

2. For \( G = (\mathbb{Z}, +), X = \{0, 1\} \), the surjective map \( \varphi : G \to X \) with \( \varphi^{-1}(1) = \mathbb{Z}_{\geq 1} \) is the unique admissible map, and \( \mathcal{M}(G, \varphi) = \{m_0\} \), where \( m_0 \) is the canonical median group operation on \( \mathbb{Z} \), corresponding to the natural simplicial tree on \( \mathbb{Z} \), so the restriction map \( \mathcal{M}(G, \varphi) \to \mathcal{M}(X) \) is obviously bijective.

3. A more interesting case is \( G = (\mathbb{Z}, +), X = \mathbb{N} \), where we have to find those median group operations \( m \) on \( \mathbb{Z} \) satisfying the strong condition that the sub-monoid \( (\mathbb{N}, +) \) is a retractible convex subset of \( (\mathbb{Z}, m) \), whence, by translation with elements \( n \in \mathbb{Z}, Z_{\geq n} \) is also retractible convex in \( (\mathbb{Z}, m) \). This task is easy since we already know, according to Remark 1.21.(2), that there are only three distinct median group operations \( m_0, m_1, m_{-1} \) on \( (\mathbb{Z}, +) \). We see that only two of them, namely \( m_0 \) and \( m_1 \), satisfy the requirement, providing the admissible maps \( \varphi_i : \mathbb{Z} \to \mathbb{N}, i = 0, 1 \), defined by

\[
\varphi_0(n) = \begin{cases} 
  n & \text{if } n \geq 0 \\
  0 & \text{if } n < 0,
\end{cases}
\]

with \( \mathcal{M}(\mathbb{Z}, \varphi_0) = \{m_0\} \), and

\[
\varphi_1(n) = \begin{cases} 
  n & \text{if } n \geq 0 \\
  0 & \text{if } n < 0 \text{ and } n \in 2\mathbb{Z} \\
  1 & \text{if } n < 0 \text{ and } n \in 2\mathbb{Z} + 1,
\end{cases}
\]

with \( \mathcal{M}(\mathbb{Z}, \varphi_1) = \{m_1\} \). Notice that \( \varphi_1 \) is the folding \( n \mapsto m_1(0, n, 1) \) associated to the linear cell \([0, 1]_{m_1} = \mathbb{N} \). Thus, with the exception of \( m_0\mid\mathbb{N} \) and \( m_1\mid\mathbb{N} \), the infinitely many median operations on the countable set \( \mathbb{N} \) do not extend to median group operations on \( (\mathbb{Z}, +) \). To extend them to suitable median group operations we are forced to forget the monoid structure of \( \mathbb{N} \) and look for larger groups containing the countable set \( \mathbb{N} \) (see Corollary 3.6).

**2 Simplicial trees induced by free actions on sets**

The main goal of this section is to explore the underlying simplicial tree of a free action on an arbitrary nonempty set, as well as its extension to a simplicial tree on a group naturally associated to the given free action, in order to use it further for obtaining by suitable deformations more general arboreal structures.
Let $H$ be a group acting freely on a nonempty set $X$. Let $B = \{b_i \mid i \in I\} \subseteq X$ be a set of representatives for the $H$-orbits. The bijection $H \times I \rightarrow X, (h, i) \mapsto hb_i$ identifies up to isomorphism the $H$-set $X$ with the cartesian product $H \times I$ with the canonical free action of the group $H$, $H \times (H \times I) \rightarrow H \times I, (h_1, (h_2, i)) \mapsto (h_1h_2, i)$. We assume that $I \cap H = \{1\}$, and we shall take $b_1 = (1, 1)$ as basepoint in $X \cong H \times I$.

Set $I' := I \setminus \{1\}, X' := \sqcup_{i \in I'} Hb_i \cong H \times I'$.

2.1 The underlying tree of the $H$-set $X$

The set $X \cong H \times I$ has a natural structure of simplicial tree with the elements of $X$ as vertices, and the ordered pairs $(b_1, hb_1), h \in H \setminus \{1\}$, and $(hb_1, hb_i), h \in H, i \in I'$, as oriented edges. Taking $b_1$ as root, we obtain a rooted order-tree $(X, b_1, \leq)$ with the partial order $\leq$ given by

$$x < y \iff \text{either } x = b_1, y \neq b_1 \text{ or } \exists h \in H \setminus \{1\}, i \in I', x = hb_1, y = hb_i,$$

and the induced meet-semilattice operation $\land$ and locally linear median operation

$$Y(x, y, z) = (x \land y) \lor (y \land z) \lor (z \land x) \in \{x \land y, y \land z, z \land x\}.$$ 

Remarks 2.1. (1) With respect to the partial order $\leq$, $b_1$ is the least element of $X$, while $X'$ is the set of all maximal elements of $X$. In particular, for $x, y \in X, x \land y \in X' \iff x = y \in X'$, and hence $x \land y \in Hb_1$ provided $x \neq y$, whence $Y(x, y, z) \in Hb_1$ whenever $x \neq y, y \neq z, z \neq x$.

(2) $Hb_1$ is a retractible convex subset of the median set $(X, Y)$, with the associated folding $\theta : X \rightarrow X, hb_1 \mapsto hb_1$, compatible with the action of $H$, i.e. $\theta(hx) = h\theta(x)$ for all $h \in H, x \in X$.

(3) The median operation $Y$ is almost compatible with the action of $H$ on $X$ in the following sense: $Y(hx, hy, hz) \in HY(x, y, z)$ for all $h \in H, x, y, z \in X$, i.e. the map $Y : X^3 \rightarrow X$ induces a map $H \setminus X^3 \rightarrow H \setminus X$. Indeed, for $h \in H, x, y, z \in X$, we obtain

$$Y(hx, hy, hz) = \begin{cases} hY(x, y, z) & \text{if } |\{\theta(x), \theta(y), \theta(z)\}| \in \{1, 2\} \\ Y(x, y, z) = b_1 & \text{if } |\{\theta(x), \theta(y), \theta(z)\}| = 3 \end{cases}$$

Consequently, the necessary and sufficient condition for the median operation $Y$ to be compatible with the action of $H$ on $X$, i.e. $hY(x, y, z) = Y(hx, hy, hz)$ for all $h \in H, x, y, z \in X$, is that either $H = 1$ or $H \cong \mathbb{Z}/2$.

2.2 The group $\hat{H}$ and its underlying tree

We denote by $F$ the free group with base $I'$, and by $\hat{H} := H \ast F$ the free product of the groups $H$ and $F$. The group $H$ is canonically identified with a subgroup of $\hat{H}$, while the injective map $i : X \rightarrow \hat{H}, hb_i \mapsto hi$, identifies the $H$-set $X \cong H \times I$ with the disjoint union $H \sqcup (\sqcup_{i \in I'} Hi) \subseteq \hat{H}$ on which $H$ acts freely by left multiplication.

Using the natural tree structure of the free group $F$, we extend as follows the underlying tree of the $H$-set $X$ as defined in 2.1. to a simplicial tree on the underlying set of the free product $\hat{H} = H \ast F$. 

Let \( l : \hat{H} \to \mathbb{N} \) denote the length function associated to the system of generators \( J = J^{-1} := (H \setminus \{1\}) \sqcup I^{\pm 1} \), so \( l(w) \) is the minimum length of any expression \( w = w_1 \cdots w_n \) with \( w_i \in J \). In particular, \( l(w) = 0 \iff w = 1 \), \( l(w^{-1}) = l(w) \) for all \( w \in \hat{H} \), and \( l(wv) \leq l(u) + l(v) \) for all \( u, v \in \hat{H} \). Since \( \hat{H} = H \ast F \) and \( F \) is free with base \( I' \), it follows that the expression of minimal length above is unique for any \( w \in \hat{H} \); call it the \textit{reduced normal form} of \( w \), and set \( o(w) := w_1 \), \( t(w) := w_n \) provided \( l(w) = n \geq 1 \). For \( u, v \in \hat{H} \), put \( u \preceq v \iff l(v) = l(u) + l(u^{-1}v) \), and write \( v = u \bullet (u^{-1}v) \) provided \( u \preceq v \). The binary relation \( \preceq \) is a partial order extending the partial order \( \leq \) on \( X \) as defined in 2.1. Moreover the partial order \( \leq \) makes \( \hat{H} \) a \textit{rooted order-tree} with 1 as distinguished base point, the \textit{root}, while the corresponding meet-semilattice operation \( \land \) and locally linear median operation \( \∧ \) on \( X \) are extensions of the operations \( \land \) and \( Y \) on \( X \).

For all \( u, v \in \hat{H} \), the cell \( [u, v] := \{ Y(u, v, w) \mid w \in \hat{H} \} \) is the union of the closed intervals \([u \land v, u]\) and \([u \land v, v]\). Since the cell \([u, v]\) has finitely many elements for all \( u, v \in \hat{H} \), \( \hat{H} \) is a \( \mathbb{Z} \)-tree with the distance function \( d : \hat{H} \times \hat{H} \to \mathbb{Z} \) defined by \( d(u, v) := |[u, v]| - 1 = l(u^{-1}v) + l(v^{-1}w) \), where \( w = u \land v \). Thus \( d(u, v) = l(u^{-1}v) \) provided \( u \preceq v \), in particular, \( d(u, 1) = l(u) \) for all \( u \in \hat{H} \), and hence \( d(u, v) = d(u, u \land v) + d(v, u \land v) \geq l(u^{-1}v) \) for all \( u, v \in \hat{H} \). Consequently, \( d(u, v) = l(u^{-1}v) \iff u^{-1}v = (u^{-1}(u \land v)) \bullet (u \land v)^{-1}v) \), while \( d(u, v) = l(u^{-1}v) + 1 \) otherwise. The latter situation holds whenever \( u \neq u \land v \neq v \) and \( o((u \land v)^{-1}u) = o((u \land v)^{-1}v) \in H \setminus \{1\} \). In graph theoretic terms, the underlying tree of \( \hat{H} \) has the elements of \( \hat{H} \) as vertices, and the ordered pairs \((u, v)\), with \( u \preceq v \), \( l(u^{-1}v) = 1 \), as oriented edges.

\( X \) is a retractible convex subset of the median set \((\hat{H}, Y)\), with the canonical retract \( \varphi : \hat{H} \to X \) defined by \( \varphi(w) := \) the greatest element \( x \in X \) for which \( x \preceq w \), i.e. \( w = x \bullet (x^{-1}w) \). Thus \( \varphi(w) = h \in H \iff w = h \lor h^{-1} \preceq w \) for some \( i \in I' \), while \( \varphi(w) = hi \) with \( h \in H, i \in I' \iff hi \preceq h \). In particular, \( H = Hb_1 \) is a retractible convex subset of the median set \((\hat{H}, Y)\) with the retract \( \hat{\vartheta} := \vartheta \circ \varphi : \hat{H} \to H \). Thus \( \hat{\vartheta}(w) = 1 \iff \) either \( w = 1 \) or \( o(w) \in I^{\pm 1} \), and \( \hat{\vartheta}(w) = h \in H \setminus \{1\} \iff o(w) = h \).

**Remark 2.2.** (1) The maps \( \varphi \) and \( \hat{\vartheta} \) are \( H \)-equivariant.

(2) Let \( u, v \in \hat{H} \) be such that \( u^{-1} \land v = 1 \). Then the following assertions are equivalent.

(i) \( \varphi(\alpha) = \varphi(u) \).

(ii) Either \( u \notin H \) or \( \varphi(v) = 1 \).

(iii) \( \varphi(ux) = \varphi(u) \) for all \( u \in \hat{H} \setminus H, x \in X \).

The next lemma collects some basic properties which describe the relation between the group \( \hat{H} \) and its underlying tree.

**Lemma 2.3.** (1) \( u \preceq v \) and \( v \preceq w \implies w^{-1}v \preceq w^{-1}u \).

(2) For \( u, v \in \hat{H} \), let \( a := u^{-1} \land v, u' := ua, v' := a^{-1}v, u'' := u' \hat{\vartheta}(u'^{-1}), v'' := \hat{\vartheta}(v'^{-1}v', h := \hat{\vartheta}(u'^{-1})^{-1} \hat{\vartheta}(v') \in H \), with \( h = 1 \iff \hat{\vartheta}(u^{-1}) = \hat{\vartheta}(v') = 1 \). Then \( uv = u''h''v'' = u'' \bullet h \bullet v'' \), i.e. \( l(uv) = l(u'') + l(h) + l(v'') \).

In particular, \( u \preceq v \iff u^{-1} \land (u^{-1}v) = 1 \) and either \( \hat{\vartheta}(u^{-1}) = 1 \) or \( \hat{\vartheta}(u^{-1}v) = 1 \).
(3) The necessary and sufficient condition for \( \hat{H} \) together with the median operation \( Y \) to be a median group is that either \( H = 1 \) or \( H \cong \mathbb{Z}/2 \).

(4) For all \( s, u, v \in \hat{H}, su \land sv \leq sY(u, v, s^{-1}), \) with \( (su \land sv)^{-1} sY(u, v, s^{-1}) \in H \).

(5) For all \( u, v, w \in \hat{H}, Y(t^{-1}u, t^{-1}v, t^{-1}w) = 1, \) where \( t := Y(u, v, w) \).

Proof. The proof of the assertions (1) and (2) is straightforward.

(3). It follows by Proposition 1.11. that the necessary and sufficient condition for \( (\hat{H}, Y) \) to be a median group is that \( u^{-1}(u \land v) \leq u^{-1}v \) for all \( u, v \in \hat{H} \). According to (2), the latter condition holds if and only if for all \( u, v \in \hat{H} \), either \( \hat{\theta}((u \land v)^{-1}u) = 1 \) or \( \hat{\theta}((u \land v)^{-1}v) = 1 \). One checks easily that the last sentence is equivalent with \( |H| \leq 2 \).

(4). Let \( s, u, v \in \hat{H} \). Setting \( a := u \land v \land s^{-1}, b := Y(u, v, s^{-1}), \) we have to show that \( sb = (su \land sv) \land p \) with \( p \in H \). We distinguish the following three cases:

(4.1.) \( a = u \land s^{-1} = v \land s^{-1} \leq b = u \land v \): We may assume without loss that \( a = 1 \) since \( s = s' \land a^{-1}, u = a \land u', v = a \land v' \) with \( a' := u' \land s'^{-1} = v' \land s'^{-1} = 1 \), therefore \( su = s'u', sv = s'v', \) and

\[
sY(u, v, s^{-1}) = (s \land u) = s'(u' \land v') = s'Y(u', v', s'^{-1}),
\]

so we may replace the elements \( u, v, s \) by \( u', v', s' \) respectively. As \( u \land s^{-1} = 1 \), it follows that either \( su = s \land u \) or \( su = (s' \land g)(h \land u') = s' \land (g \land u') \) where \( g, h \in H \setminus \{1\}, gh \neq 1 \). A similar alternative holds for the pair \( (s, v) \). Thus we have the following possible situations:

(4.1.1.) \( su = s \land u, sv = s \land v \): Then \( su \land sv = s \land b, so \ p = 1 \).

(4.1.2.) \( su \neq s \land u, sv = s \land v \): Then \( su = s' \land g, u = h \land u' \) with \( g, h \in H \setminus \{1\}, gh \neq 1 \), therefore \( su = s' \land (gh) \land u', \) and either \( v = 1 \) or \( \theta(v) \in I'^{\pm 1} \). Consequently, \( b = 1, su \land sv = s', sb = s \land p \) with \( p = g \in H \setminus \{1\} \).

(4.1.3.) \( su = s \land u, sv \neq s \land v \): We proceed as in case (4.1.2).

(4.1.4.) \( su \neq s \land u, sv \neq s \land v \): Then \( su = s' \land g, u = h_1 \land u', v = h_2 \land v' \) with \( g, h_j \in H \setminus \{1\}, gh_j \neq 1, j = 1, 2 \). We have the alternative: either \( h := h_1 = h_2 \) or \( h_1 \neq h_2 \). In the first case we obtain \( b = h \land (u' \land v'), sb = su \land svg = s' \land (gh) \land (u' \land v'), \) so \( p = 1 \), while in the second case we get \( b = 1, su \land sv = s', sb = s \land p \) with \( p = g \in H \setminus \{1\} \) as desired.

(4.2.) \( a = u \land s^{-1} = u \land v < b = v \land s^{-1} \): As in case (4.1.), we may assume that \( a = 1 \). We get \( s = s' \land b^{-1}, v = b \land v' \) with \( u \land b = v' \land s'^{-1} = 1 \). We have to show that \( s' = (s'b^{-1} \land s'v') \land p \) with \( p \in H \).

We have the following possible situations:

(4.2.1.) \( b^{-1}u = b^{-1} \land u, s'v' = s' \land v' \): Then \( s'b^{-1}u \land s'v' = s' \), so \( p = 1 \).

(4.2.2.) \( b^{-1}u \neq b^{-1} \land u, s'v' \neq s' \land v' \): Then \( s' = s' \land g, v' = h \land v'' \) with \( g, h \in H \setminus \{1\}, gh \neq 1 \). The desired result follows with \( p = g \in H \setminus \{1\} \).

(4.2.3.) \( b^{-1}u \neq b^{-1} \land u, s'v' = s' \land v' \): Then \( b = g \land b', u = h \land u' \) with \( g, h \in H \setminus \{1\}, gh \neq 1 \). First let us assume that \( b' \neq 1 \). Since \( s = s' \land b^{-1} \), it follows that \( s'b^{-1}u = s' \land b^{-1} \land (g^{-1}h) \land u' \). As \( v = b \land v' = g \land b' \land v' \), we deduce that \( v' \land b'^{-1} = 1 \). Since \( s'v' = s' \land v' \) by assumption, the required result follows with \( p = 1 \).
Next let us assume that \( b' = 1 \), i.e. \( b = g \in H \setminus \{1\} \). Then \( b^{-1}u = (g^{-1}h) \cdot u', s = s' \cdot b^{-1} = s' \cdot g^{-1} \), therefore either \( s' = 1 \) or \( t(s') \in I^{1+} \). Consequently, \( s'b^{-1}u = s' \cdot (g^{-1}h) \cdot u' \). On the other hand, since \( v = b \cdot v' = g^{-1} \cdot v' \), it follows that either \( v' = 1 \) or \( o(v') \in I^{1+} \), and hence \( v' \land (g^{-1}h) = 1 \). As \( s'v' = s' \cdot v' \), we get as above the desired result with \( p = 1 \).

\[ (4.2.4.) \quad b^{-1}u \neq b^{-1} \cdot u, s'v' \neq s' \cdot v' \] According to \((4.2.3.)\) we get \( s' \leq s'b^{-1}u \).

On the other hand, it follows by assumption that \( s' = s'' \cdot g', v' = h' \cdot v'' \) with \( g', h' \in H \setminus \{1\}, g'h' \neq 1 \). Thus \( s'v' \land s' = (s' \cdot (g'h') \cdot v'') \land (s'' \cdot g') = s'' < s' \), and hence the required result with \( p = g' \in H \setminus \{1\} \).

\[ (4.3) \quad a = v \land s^{-1} = u \land v < b = u \land s^{-1} \] We proceed as in case \((4.2.)\).

\( (5) \) Let \( u, v, w \in \widehat{H}, t := Y(u, v, w) \). Since \( Y(u, v, t) = t \), it follows by \((4)\) that \( t^{-1}u \land t^{-1}v \leq t^{-1}Y(u, v, t) = 1 \), therefore \( t^{-1}u \land t^{-1}v = 1 \), and similarly, \( t^{-1}v \land t^{-1}w = t^{-1}w \land t^{-1}u = 1 \), and hence \( Y(t^{-1}u, t^{-1}v, t^{-1}w) = 1 \) as desired.

3 The deformation of the underlying tree of \( \widehat{H} \) into median group operations

Let \( H \) be a group acting freely on a nonempty set \( X \). As shown in Section 2, the free action \( H \times X \to X \) is extended through the \( H \)-equivariant retract \( \varphi : \widehat{H} \to X \), to the transitive and free action of the group \( \widehat{H} = H \ast F \) on itself given by left multiplication. Thus the conditions \((1)\) and \((2)\) of Theorem 1 (see Introduction) are obviously satisfied.

We denote by \( \mathcal{M}(X) \) the set of all median operations \( m \) on \( X \) which are compatible with the action of \( H \), while by \( \mathcal{M}(\widehat{H}, \varphi) \) we denote the set of those median group operations \( \widehat{m} \) on \( \widehat{H} \) for which the retract \( \varphi \) is a folding identifying \( X \) with a retractable convex subset of the median set \( (\widehat{H}, \widehat{m}) \). We denote by \( \mathcal{M}_t(X), \mathcal{M}_t(\widehat{H}, \varphi) \) \((\mathcal{M}_s(X), \mathcal{M}_s(\widehat{H}, \varphi))\) the subsets of \( \mathcal{M}(X) \) and \( \mathcal{M}(\widehat{H}, \varphi) \) respectively consisting of those median operations which are locally linear (simplicial). According to Lemma 1.2.4., the restriction map \( \text{res} : \mathcal{M}(\widehat{H}, \varphi) \to \mathcal{M}(X) \) is injective, whence the induced maps \( \text{res}_t : \mathcal{M}_t(\widehat{H}, \varphi) \to \mathcal{M}_t(X) \) and \( \text{res}_s : \mathcal{M}_s(\widehat{H}, \varphi) \to \mathcal{M}_s(X) \) are injective too.

The present section is devoted to the proof of a more explicit version of Theorem 1. With the notation above we obtain

**Theorem 3.1.** The map \( \text{res} : \mathcal{M}(\widehat{H}, \varphi) \to \mathcal{M}(X) \) is bijective. Let \( m \in \mathcal{M}(X) \). Then the following assertions hold.

\((1)\) The unique median group operation \( \widehat{m} \in \mathcal{M}(\widehat{H}, \varphi) \) lying over \( m \) is a deformation of the underlying simplicial tree of \( \widehat{H} \) induced by the median operation \( m \) and the retract \( \varphi \), defined by

\[ \widehat{m}(u, v, w) = t m(\varphi(t^{-1}u), \varphi(t^{-1}v), \varphi(t^{-1}w)) \]

for \( u, v, w \in \widehat{H} \), where \( t = Y(u, v, w) \).
(2) The induced meet-semilattice operation \( u \cap v := \hat{m}(u, 1, v) \) is a deformation of the meet-semilattice operation \( \land \), defined by

\[
u \cap v = (u \land v)m(\varphi((u \land v)^{-1}u), \varphi((u \land v)^{-1}), \varphi((u \land v)^{-1})v)\]

for \( u, v \in \hat{H} \).

(3) The induced partial order \( \subseteq \) is defined by

\[
u \subseteq v \iff u \subseteq (u \land v)^{-1}u \subseteq [\varphi((u \land v)^{-1}), \varphi((u \land v)^{-1})] \subseteq X.
\]

In particular, \( u \subseteq v \) provided \( u \subseteq v \) and \( 1 \subseteq [\varphi(u^{-1}), \varphi(u^{-1})] \).

Proof. Let \( m \in M(X) \). We have to define a median group operation \( \hat{m} \in M(\hat{H}, \varphi) \) such that \( \hat{m}(x, y, z) = m(x, y, z) \) for all \( x, y, z \in X \). Since \( m \) is compatible with the action of \( H \), the group \( H \) acts from the right on \( Spec(X, m) \) according to the rule \( p^h := h^{-1}p = \{h^{-1}x \mid x \in p\} \) for \( p \in Spec(X, m), h \in H \).

On the other hand, we consider the natural action from the right of the group \( \hat{H} \) on the power set \( P(\hat{H}), (P, u) \mapsto Pu := u^{-1}P = \{u^{-1}v \mid v \in P\} \). Let

\[
S := \{\varphi^{-1}(p)^u = u^{-1}\varphi^{-1}(p) \mid p \in Spec(X, m), u \in \hat{H}\}
\]

be the \( \hat{H} \)-orbit of the subset \( \varphi^{-1}(Spec(X, m)) \).

The set \( S \) is closed under the involution \( P \mapsto \hat{H} \setminus P \) which is compatible with the action of \( \hat{H} \), i.e. \( \hat{H} \setminus (P^u) = (\hat{H} \setminus P)^u \) for all \( P \in S, u \in \hat{H} \).

Let \( P = \varphi^{-1}(p)^u \in S \setminus \{\varnothing, \hat{H}\} \), whence \( p \neq \varnothing, X \). Then \( P \cap X = \{x \in X \mid \varphi(ux) \in p\} \). We distinguish the following three cases.

(i) \( u \in H \). Then \( P \cap X = p^u \in Spec(X, m) \setminus \{\varnothing, X\} \) and \( P = \varphi^{-1}(p^u) \in \varphi^{-1}(Spec(X, m) \setminus \{\varnothing, X\}) \).

(ii) \( u \notin H \) and \( \varphi(u) \notin p \). Then \( \varphi(ux) = \varphi(u) \in p \) for all \( x \in X \), by Remark 2.2.(3), whence \( X \subseteq P \).

(iii) \( u \notin H \) and \( \varphi(u) \notin X \setminus p \). Then \( X \subseteq \hat{H} \setminus P \) by (ii), and hence \( P \cap X = \varnothing \).

Consequently, the \( H \)-equivariant retract \( \varphi : \hat{H} \to X \) of the \( H \)-equivariant embedding \( X \to \hat{H} \) induces a \( H \)-equivariant embedding \( Spec(X, m) \to \hat{S}, p \mapsto \varphi^{-1}(p) \) with the \( H \)-equivariant retract \( \hat{S} \to Spec(X, m), P \mapsto P \cap X \), and \( \varphi^{-1}(Spec(X, m)) = \{\varnothing, \hat{H}\} \cup \{P \in S \mid P \cap X \notin \{\varnothing, X\}\} \).

\( \hat{H} \) acts canonically on the power set \( P(S) \) according to the rule

\[
uU := \{P^{-u^{-1}} = uP \mid P \in U\} \text{ for } u \in \hat{H}, \hat{U} \subseteq S.
\]

Define the negation operator on \( P(S), U \mapsto \neg U := \{P \in S \mid \hat{H} \setminus P \notin \hat{U}\} \). It follows that \( \neg U \subseteq \neg V \iff V \subseteq \hat{U}, \neg(\hat{U} \cup V) = (\neg \hat{U}) \cap (\neg V), \neg(\hat{U} \cap V) = (\neg \hat{U}) \cup (\neg V), \) and \( \neg(\neg \hat{U}) = \hat{U} \) for \( \hat{U}, \hat{V} \subseteq \hat{S} \). In addition, the operator \( \neg \) is compatible with the action of \( \hat{H} \), i.e. \( \neg(uU) = u(\neg U) \) for all \( u \in \hat{H}, \hat{U} \subseteq S \).

The group \( \hat{H} \) and the power set \( P(S) \) are also related through the map

\[
\hat{H} \to P(S), u \mapsto U(u) := \{P \in S \mid u \notin P\}.
\]

\textsuperscript{6)} See [11, Theorem 3.1.] for an alternative more technical proof.
Notice that \( -U(u) = U(u) \) and \( uU(v) = U(uv) \) for \( u, v \in \hat{H} \), so \( \hat{H} \) acts transitively on the \( \neg \)-invariant set \( \{U(u) \mid u \in \hat{H}\} \). To show that the action is free, let \( u \in \hat{H} \setminus \{1\} \). It suffices to show that \( U(u) \not\subseteq U(1) \). We distinguish the following two cases.

(i) \( \varphi(u) \neq 1 \). Then, by Theorem 1.6.(1), there is \( p \in \text{Spec}(X,m) \) such that \( 1 \in p, \varphi(u) \notin p \), and hence \( \varphi^{-1}(p) \in U(u) \setminus U(1) \).

(ii) \( \varphi(u) = 1 \). Then, since \( u \neq 1 \), it follows that \( u = i^{-1} \circ v \) for some \( i \in I', v \in \hat{H} \) with \( \varphi(v) \neq i \). Consequently, by Theorem 1.6.(1) again, there is \( p \in \text{Spec}(X,m) \) such that \( i \in p, \varphi(v) \notin p \), therefore \( \varphi^{-1}(p)^\dagger \in U(u) \setminus U(1) \) as required.

To obtain the desired median group operation \( \hat{m} \) on \( \hat{H} \), identified through the injective map \( u \mapsto U(u) \) with a \( \hat{H} \)-subset of \( \mathcal{P}(S) \), we have to show that the subset \( \{U(u) \mid u \in \hat{H}\} \) is closed under the canonical median operation \( m \) on \( \mathcal{P}(S) \)

\[
m(U, V, W) := (U \cap V) \cup (V \cap W) \cup (W \cap U) = (U \cup V) \cap (V \cup W) \cap (W \cup U),
\]

which is compatible with the action of \( \hat{H} \), i.e. \( u m(U, V, W) = m(uU, uV, uW) \) for \( u \in \hat{H}, U, V, W \subseteq S \).

Taking into account the invariance of the \( U(u) \)'s under the negation operator \( \neg \), it suffices to show that for arbitrary \( u, v, w \in \hat{H} \), \( m(U(u), U(v), U(w)) \subseteq U(x) \), where \( t := Y(u,v,w), x := m(\varphi(t^{-1}u), \varphi(t^{-1}v), \varphi(t^{-1}w)) \). Using the compatibility of the median operation \( m \) with the action of \( \hat{H} \) and the fact that \( Y(t^{-1}u, t^{-1}v, t^{-1}w) = 1 \) by Lemma 2.3.(5), it remains to show that \( m(U(u), U(v), U(w)) \subseteq U(x) \), where \( x := m(\varphi(u), \varphi(v), \varphi(w)) \), for \( u, v, w \in \hat{H} \) satisfying \( Y(u, v, w) = 1 \). Consequently, it suffices to show that \( U(u) \cap U(v) \subseteq U(x) \) provided \( u \wedge v = 1 \) and \( x \) belongs to the cell \( [\varphi(u), \varphi(v)] \) of the median set \( (X, m) \)\(^7\). Assuming the contrary, let \( P \in \mathcal{S} \) be such that \( x \in P, u, v \notin P \), in particular, \( P \neq \hat{H} \) and \( P \cap X \neq \emptyset \). We distinguish the following two cases.

- (i) \( p := P \cap X \neq X \), whence \( P = \varphi^{-1}(p) \). As \( x \in [\varphi(u), \varphi(v)] \cap p \), it follows that either \( \varphi(u) \in p \) or \( \varphi(v) \in p \), whence either \( u \in P \) or \( v \in P \), and hence a contradiction.
- (ii) \( X \subseteq P \), whence \( P = \varphi^{-1}(q) \)\(^8\) for some \( q \in \text{Spec}(X,m) \setminus \{\emptyset, X\}, s \in \hat{H} \setminus H \) with \( \varphi(s) \in q \). Since \( u \wedge v = 1 \) by assumption, it follows that either \( s^{-1} \wedge u = 1 \) or \( s^{-1} \wedge v = 1 \), therefore \( \varphi(su) = \varphi(s) \in q \) or \( \varphi(sv) = \varphi(s) \in q \) according to Remark 2.2.(2). Consequently, either \( u \in P \) or \( v \in P \), again a contradiction.

Thus we have obtained the desired median group operation \( \hat{m} : \hat{H}^3 \to \hat{H} \), inducing the meet-semilattice operation \( \cap \) and the partial order \( \subset \) as defined in the statements (2) and (3) of the theorem. One checks easily that \( \text{res}(\hat{m}) = m \) and \( \varphi \) is a folding of the median set \( (\hat{H}, \hat{m}) \) as required. According to Lemma 1.22., \( \hat{m} \) is unique with the properties above, and \( \text{Spec}(\hat{H}, \hat{m}) = \mathcal{S} \). This completes the proof.

\(\square\)

The next lemma provides equivalent descriptions for the partial order \( \subset \).

**Lemma 3.2.** Let \( m \in \mathcal{M}(X) \) and \( \subset \) be the partial order induced by the unique median group operation \( \hat{m} \in \mathcal{M}(\hat{H}, \varphi) \) lying over \( m \). Then the following assertions are equivalent for \( u, v \in \hat{H} \).

---

\(^7\) For \( x, y \in X \), the cell \([x, y]\) of the median set \((X, m)\) must not be confused with the cell \([x, y]\) of the median set \((X, Y)\) as defined in 2.1.

\(^8\) For other descriptions of the partial order \( \subset \) see [\[\] Lemma 3.5.]
(1) $u \subset v$.

(2) $U(1) \cap U(v) \subseteq U(u)$, where $U(w) := \{P \in S \mid w \notin P\}$ for $w \in \tilde{H}$, $S := \text{Spec}(\tilde{H}, \tilde{m})$.

(3) There is $w \in \tilde{H}$ such that $w \leq v$ and $w^{-1}u \in [\varphi(w^{-1}), \varphi(w^{-1}v)] \subseteq X$.

(4) Either $u = v = 1$ or there is $w \in \tilde{H}$ such that

$$w \leq v, \varphi(w^{-1}) \in I, \varphi(w) = 1 \Longrightarrow \varphi(w^{-1}v) \neq 1, w^{-1}u \in [\varphi(w^{-1}), \varphi(w^{-1}v)] \subseteq X,$$

whence $w\varphi(w^{-1}) \subset u \subset w\varphi(w^{-1}v) \subset v$, while $w\varphi(w^{-1}) < w \cdot \varphi(w^{-1}v) \leq v$.

Proof. (1) $\iff$ (2) follows by Theorem 1.6.(1), while (4) $\implies$ (3) is obvious.

(1) $\implies$ (4). Let $u, v \in \tilde{H}$ be such that $u \subset v$. If $v = 1$ then $u = 1$, so let us assume that $v \neq 1$. Setting $a := u \land v, u = a \cdot b, v = a \cdot c$ with $b \land c = 1$, we have by assumption $b \in [\varphi(a^{-1}), \varphi(c)]$. We distinguish the following three cases.

(i) $\varphi(a^{-1}) \in I$, with $\varphi(c) \neq 1$ provided $\varphi(a^{-1}) = 1$. Then $w := a$ satisfies the requirements.

(ii) $\varphi(a^{-1}) = \varphi(c) = 1$. Then $b = 1, u = a \leq v = u \cdot c$. As $v \neq 1$ it follows that either $u \neq 1$ or $c \neq 1$.

First assume that $u \neq 1$, whence $u = u' \cdot i$ with $i \in I'$ since $\varphi(u^{-1}) = 1, u \neq 1$ by assumption. Then $w := u'$ satisfies the required conditions provided $\varphi(u^{-1}) \in I$. Assuming that $\varphi(u^{-1}) \notin I$, we obtain $u = u'' \cdot h \cdot i$ with $h \in H \setminus \{1\}, \varphi(u''^{-1}) \in I$, therefore $w := u''$ satisfies the requirements.

Next assume that $c \neq 1$, whence $c = i^{-1} \cdot c'$ with $i \in I'$ since $\varphi(c) = 1, c \neq 1$. Then $w := u \cdot i^{-1}$ satisfies the required conditions.

(iii) $\varphi(a^{-1}) \notin I$, whence $a = w \cdot h$ with $h \in H \setminus \{1\}, \varphi(w^{-1}) \notin I$. Then $\varphi(w^{-1}v) = \varphi(h \cdot c) = h \cdot \varphi(c) \neq 1$, and $w^{-1}u = h \cdot b \in h[\varphi(a^{-1}), \varphi(c)] = [\varphi(w^{-1}), \varphi(w^{-1}v)]$ as desired.

One checks easily that in all the cases above, $w\varphi(w^{-1}) < w\varphi(w^{-1}v) \leq v$ and $w\varphi(w^{-1}) \subset u \subset w\varphi(w^{-1}v) \subset v$.

(3) $\implies$ (2). Let $u, v \in \tilde{H}$ be such that $w^{-1}u \in [\varphi(w^{-1}), \varphi(w^{-1}v)] \subseteq X$ for some $w \leq v$. Assuming that $U(1) \cap U(v) \subseteq U(u)$, let $P \in S$ be such that $1, v \notin P, u \in P$, whence $w^{-1}, w^{-1}v \notin Q, w^{-1}u \in Q$, where $Q := P^w$. As $w^{-1}u \in X$ by assumption, it follows that $Q \cap X \neq \emptyset$, and hence there are the following two possibilities.

(i) $q := Q \cap X \neq X$, whence $Q = \varphi^{-1}(q)$. As $w^{-1}, w^{-1}v \notin Q$, we obtain $\varphi(w^{-1}), \varphi(w^{-1}v) \in X \setminus q$, therefore, by Theorem 1.6.(1), $q \cap [\varphi(w^{-1}), \varphi(w^{-1}v)] = \emptyset$, contrary to the assumption that $w^{-1}u \in q \cap [\varphi(w^{-1}), \varphi(w^{-1}v)]$.

(ii) $X \subseteq Q$, whence $Q = \varphi^{-1}(q)^s$ for some $q \in \text{Spec}(X, m) \setminus \{\emptyset, X\}, s \in \tilde{H} \setminus H$ with $\varphi(s) \in q$. As $w^{-1}, w^{-1}v \notin Q$, we obtain $\varphi(sw^{-1}), \varphi(sw^{-1}v) \in X \setminus q$. On the other hand, since $w \leq v$, it follows that $w^{-1} \land w^{-1}v = 1$, and hence either $s^{-1} \land w^{-1} = 1$ or $s^{-1} \land w^{-1}v = 1$. Consequently, by Remark 2.2.(2), we deduce that either $\varphi(sw^{-1}) = \varphi(s) \in q$ or $\varphi(sw^{-1}v) = \varphi(s) \in q$, i.e. a contradiction. This finishes the proof. □

To any $v \in \tilde{H} \setminus \{1\}$ we associate the following two sets

$$C_v := \{w \in \tilde{H} \mid w \leq v, \varphi(w^{-1}) \in I, \varphi(w^{-1}) = 1 \implies \varphi(w^{-1}v) \neq 1\}$$
and
\[ O_v := \{ w \varphi(w^{-1}) \mid w \in C \}, \]

together with the map \( \zeta : C_v \rightarrow O_v \) defined by \( \zeta(w) = w \varphi(w^{-1}) \), whence \( \zeta(w) \leq w \) for \( w \in C_v \). \( C_v \) and \( O_v \) are nonempty finite sets, totally ordered with respect to \( \leq \), and the map \( \zeta \) is an isomorphism of totally ordered sets. Setting \( C_v = \{ w_i \mid i = 1, n \} \) with \( n \geq 1, w_i < w_{i+1}, \) it follows that \( \zeta(w_1) = 1, w_i \leq \zeta(w_{i+1}) = w_i \varphi(w_i^{-1}v) \) for \( i < n \), and \( \zeta(w_n) < v = w_n \varphi(w_n^{-1}v) \). Thus the totally ordered finite set \( \{1, v\} \) is the union of \( n \) adjacent proper closed intervals \( J_i := [\zeta(w_i), \zeta(w_{i+1})], i = 1, n - 1, J_n := [\zeta(w_n), v] \) with \( w_i \in J_i, i = 1, n \). Call this decomposition in adjacent closed intervals the combinatorial configuration associated to the element \( v \in \hat{H} \setminus \{1\} \).

For instance, taking \( v = i^{-2}h^{-3}g \) with \( h, g \in H \setminus \{1\}, i, j \in I', l(v) = 7 \), we obtain
\[ C_v = \{ i^{-1}, i^{-2}, i^{-2}hj, i^{-2}hj^2, i^{-2}hj^3 \}, O_v = \{ 1, i^{-1}, i^{-2}hj, i^{-2}hj^2, i^{-2}hj^3 \} \]
of cardinality \( n = 5 \), and the adjacent closed intervals
\[ J_1 = [1, i^{-1}], J_2 = [i^{-1}, i^{-2}hj], J_3 = [i^{-2}hj, i^{-2}hj^2], J_4 = [i^{-2}hj^2, i^{-2}hj^3], J_5 = [i^{-2}hj^3, v] \]
of cardinality \( 2, 4, 2, 2, 2 \) respectively.

As a consequence of Lemma 3.2. and Corollaries 1.19., 1.20., we obtain

**Corollary 3.3.** Let \( m \in M(X) \) and \( \subset \) be the partial order induced by the unique median group operation \( \hat{m} \in M(\hat{H}, \varphi) \) lying over \( m \). Then, for any \( v \in \hat{H} \setminus \{1\} \), the cell \( \{1, v\} \) of the median group \( (\hat{H}, \hat{m}) \), a bounded distributive lattice with respect to the partial order \( \subset \), is a deformation, induced by the median operation \( m \) on \( X \), of the combinatorial configuration associated to the element \( v \), in the following sense. Let \( C_v = \{ w_i \mid i = 1, n \}, O_v = \{ \zeta(w_i) \mid i = 1, n \} \), and the adjacent closed intervals \( J_i, i = 1, n, n \geq 1 \), as defined above. Then the following assertions hold.

1. \( 1 = \zeta(w_1) \subset \zeta(w_2) \subset \cdots \subset \zeta(w_n) \subset v. \)

2. The cell \( \{1, v\} \) of the median group \( (\hat{H}, \hat{m}) \) is the union of the adjacent cells \( J_i := [\zeta(w_i), \zeta(w_{i+1})] = w_i[\varphi(w_i^{-1})], \varphi(w_i^{-1}v)] \subseteq w_iX \) for \( i < n \) and \( J_n := [\zeta(w_n), v] = w_n[\varphi(w_n^{-1})], \varphi(w_n^{-1}v)] \subseteq w_nX \), with the partial order \( \subset \) given by \( u \subseteq u' \) for \( u \in J_i, u' \in J_k, i < k \), and \( u \subseteq u' \iff w_i^{-1}u \in [\varphi(w_i^{-1})], w_i^{-1}u' ] \subseteq X \) for \( u, u' \in J_i \).

Consequently, the median group \( (\hat{H}, \hat{m}) \) is locally linear (simplicial) provided the median set \( (X, m) \) is so. Thus the restriction maps \( \text{res}_i : M_i(\hat{H}, \varphi) \rightarrow M_i(X) \) and \( \text{res}_s : M_s(\hat{H}, \varphi) \rightarrow M_s(X) \) are bijective.

Thanks to Theorem 3.1. and Corollary 3.3., we can complete Lemma 1.14. as follows.

**Corollary 3.4.** Let \( G \) be a group. Then the following assertions are equivalent.

1. \( G \) acts freely on some nonempty median set (locally linear median set, simplicial median set).
(2) $G$ is embeddable into the underlying group of some median group (locally linear median group, simplicial median group).

**Remark 3.5.** According to Lemma 1.14., the groups acting freely on median sets form a quasivariety MSFG axiomatized by very simple quasi-identities. On the other hand, the class of groups acting freely on locally linear median sets is axiomatized by the set of all universal sentences in the first-order language of groups which are true in every locally linear median group. It would be of some interest to find a more concrete axiomatization, as well as a characterization of the finitely generated members of the class above. Concerning free actions on simplicial median sets, similar questions arise: characterize the (finitely generated) groups acting freely on simplicial median sets, as well as the models of the theory in the first-order language of groups consisting of all universal sentences which are true in every simplicial median group.

In particular, taking $H = 1$ in the statements above, we obtain

**Corollary 3.6.** Let $X = (X, m)$ be a nonempty median set. Then there exist a median group $F = (F, \hat{m})$ and an embedding $\iota : X \rightarrow F$ of median sets such that $1 \in (\iota(X)$, $\iota(X) \setminus \{1\}$ freely generates the group $F$, and $\iota(X)$ is a retractable convex subset of $F$. In addition, the median group $F$ is locally linear (simplicial) provided the median set $X$ is so.

**Example 3.7.** Let $F$ be the free group of rank 3 with generators $x_i$, $i = 1, 2, 3$, and let $X = \{1, x_1, x_2, x_3\}$. Define the retract $\varphi : F \rightarrow X$ of the embedding $X \rightarrow F$ by $\varphi(w) = \begin{cases} x_i & \text{if } x_i \leq w \\ 1 & \text{if } \text{either } w = 1 \text{ or } x_i^{-1} \leq w \text{ for some } i \in \{1, 2, 3\}\end{cases}$

The set $\mathcal{M}(X)$ of median operations on $X$ has 7 elements: 4 triangles and 3 squares. If $m$ is the median operation of the triangle with vertices $x_1, x_2, x_3$, so $m(x_1, x_2, x_3) = 1$, then the unique median group operation $\hat{m} \in \mathcal{M}(F, \varphi)$ with $\text{res} (\hat{m}) = m$ is the median operation of the canonical simplicial tree on $F$ determined by the base $\{x_1, x_2, x_3\}$. If $m$ is the median operation of the triangle with vertices $1, x_1, x_2$, so $m(1, x_1, x_2) = x_1 \cap x_2 = x_3$, then its extension $\hat{m}$ is the median operation of the simplicial tree on $F$ determined by the base $\{x^{-1}_3, x^1_1, x^{-1}_1, x_3\}$. The median group operations corresponding to the other two triangles are obtained in a similar way.

On the other hand, if $m$ is the median operation of the square with the pairs $(1, x_2), (x_1, x_3)$ of opposite vertices, then the corresponding median group $(F, \hat{m})$ is simplicial, but not locally linear, with the set $\{w \in F \setminus \{1\} | [1, w] = \{1, w\}\} = \{x_1^{\pm 1}, x_3^{\pm 1}, (x^{-1}_1 x_2)^{\pm 1}, (x^{-1}_3 x_2)^{\pm 1}\}$ of cardinality 8, and the set $\{w \in F | [1, w] = \square\} = \{x_2^{\pm 1}, (x^{-1}_1 x_3)^{\pm 1}\}$ of cardinality 4. For any $v \in F \setminus \{1\}$, the cell $[1, v]$ is a finite union of adjacent segments and/or squares. For instance, taking $v = x^{-2}_1 x_2 x^2_3 x_2$, the cell $[1, v]$ is the union of the 4 adjacent segments $[1, x^{-1}_1] = x^{-1}_1 [x_1, 1], [x^{-1}_1, x^{-1}_1 x_2], [x^{-2}_1 x_2, x^{-2}_1 x_2 x^2_3] = x^{-2}_2 x_2 [1, x_3], [x^{-2}_1 x_2 x_3, x^{-2}_1 x_2 x^2_3] = x^{-2}_1 x_2 x^2_3 [1, x_3]$ and of the square $[x^{-2}_1 x_2 x^2_3, v] = x^{-2}_3 x^{-2}_2 [1, x_2]$. The cases of the other two squares on $X$, with the pairs of opposite vertices $(1, x_1), (x_2, x_3)$ and $(1, x_3), (x_1, x_2)$ respectively, are similar.
4 The relatively-transitive closure of a free action on a median set

In this section we extend a given free action on a median set to a larger one with a suitable universal property. By iterating this construction, we shall obtain in the next section the transitive closure of any given free action on a median set.

Let $H$ be a group acting freely on a median set $X = (X, m)$. Fix as in the previous sections a set $B = \{b_i \mid i \in I\}$ of representatives of the $H$-orbits, with $1 \in I, I' := I \setminus \{1\}$. Let $\tilde{H} = H \ast F$ be the free product of $H$ and the free group $F$ with base $I'$, and identify $X$ to the $H$-subset $H \cup (\bigcup_{i \in I'} Hi) \subseteq \tilde{H}$, with the $H$-equivariant retract $\varphi : \tilde{H} \twoheadrightarrow X$.

With the notation above, the main result of this section (Theorem 2 from Introduction) reads as follows.

**Theorem 4.1.** There exist a median set $\hat{X} = (\hat{X}, \hat{m})$ and a free action of $\tilde{H}$ on $\hat{X}$ such that, identifying $\tilde{H}$ with the $\tilde{H}$-orbit of a base point of $\hat{X}$, the composition of the maps $X \rightarrow \tilde{H}, \tilde{H} \rightarrow \hat{X}$ is a $H$-equivariant embedding of median sets $X \rightarrow \hat{X}$ satisfying the following universal property.

(RTUP) For every group $H$ acting freely on a median set $\tilde{X} = (\tilde{X}, \tilde{m})$, every morphism $(\psi_0, \psi) : (H, \tilde{X}) \rightarrow (\tilde{H}, \hat{X})$ in the category FAMS of free actions on median sets, satisfying $\psi(X) \subseteq H\psi(1)$, extends uniquely to a morphism $(\hat{\psi}_0, \hat{\psi}) : (H, \hat{X}) \rightarrow (\tilde{H}, \hat{X})$ in FAMS.

In particular, the free action $(\tilde{H}, \hat{X})$ satisfying (RTUP), called the relatively-transitive closure of the free action $(H, X)$, is unique up to a unique isomorphism.

**Proof.** To construct the median set $\hat{X}$, we consider the natural action from the right of $\tilde{H}$ on the power set $\mathcal{P}(\tilde{H})$, $P^u := u^{-1}P = \{u^{-1}v \mid v \in P\}$ for $u \in \tilde{H}, P \subseteq \tilde{H}$, and let

$$\mathcal{S} := \{P \subseteq \tilde{H} \mid \forall u \in \tilde{H}, P^u \cap X \in \text{Spec} X\}.$$

The set $\mathcal{S}$ is stable under the action of $\tilde{H}$, is closed under the involution $P \mapsto \tilde{H} \setminus P$, and contains the $\tilde{H}$-set $S := \{\varphi^{-1}(p)^u \mid p \in \text{Spec} X, u \in \tilde{H}\}$. Recall that, according to Theorem 3.1., $S = \text{Spec}(\tilde{H}, \tilde{m})$, where $\tilde{m} : H^3 \rightarrow \tilde{H}$ is the unique median group operation for which $X = (X, m)$ is a retractible convex median subset of $(\tilde{H}, \tilde{m})$ with associated folding $\varphi$. Thus we obtain the $H$-equivariant embedding $\text{Spec} X \rightarrow \mathcal{S}, p \mapsto \varphi^{-1}(p)$ with the $H$-equivariant retract $\mathcal{S} \rightarrow \text{Spec} X, P \mapsto P \cap X$.

$\tilde{H}$ acts canonically on the power set $\mathcal{P}(\mathcal{S}) : u \mathfrak{M} := \{P^{u^{-1}} = uP \mid P \in \mathfrak{M}\}$ for $u \in \tilde{H}, \mathfrak{M} \subseteq \mathcal{S}$, and the action is compatible with the negation operator $\mathfrak{M} \mapsto -\mathfrak{M} := \{P \in \mathcal{S} \mid \tilde{H} \setminus P \notin \mathfrak{M}\}$. Consider the map $\tilde{H} \rightarrow \mathcal{P}(\mathcal{S}), u \mapsto \mathfrak{U}(u) := \{P \in \mathcal{S} \mid u \notin P\}$ which maps $\tilde{H}$ onto the $\tilde{H}$-orbit of $\mathfrak{U}(1)$. Composing the map above with the restriction map $\mathcal{P}(\mathcal{S}) \rightarrow \mathcal{P}(S), \mathfrak{M} \mapsto \mathfrak{M} \cap S$, we obtain the injective map $\tilde{H} \rightarrow \mathcal{P}(S)$ (see the proof of Theorem 3.1.) Consequently, the map $\tilde{H} \rightarrow \mathcal{P}(\mathcal{S})$ is injective too, whence the transitive action of $\tilde{H}$ on the set $\{\mathfrak{U}(u) \mid u \in \tilde{H}\}$ is free. Notice also that $-\mathfrak{U}(u) = \mathfrak{U}(u)$ for all $u \in \tilde{H}$.

Let us now consider the sublattice $\mathfrak{L}$ of the boolean algebra $\mathcal{P}(\mathcal{S})$ generated by the subsets $\mathfrak{U}(u) = u\mathfrak{U}(1), u \in \tilde{H}$. As $\mathfrak{S} \in \mathfrak{U}(u), \tilde{H} \notin \mathfrak{U}(u)$ for all $u \in \tilde{H}$, it follows that
\[ \mathcal{L} \subseteq \mathcal{P}(\mathcal{S}) \setminus \{\varnothing, \mathcal{S}\}. \] More precisely, any element of \( \mathcal{L} \) has the form \( \bigcup_{i=1}^{n} \mathcal{U}(F_i) \), \( n \geq 1 \), where the \( F_i \)'s are nonempty finite subsets of \( \hat{H} \), and

\[
\mathcal{U}(F_i) := \bigcap_{u \in F_i} \mathcal{U}(u) = \{ P \in \mathcal{S} | P \cap F_i = \varnothing \}, i = 1, \ldots, n.
\]

Consequently, \( \mathcal{L} \) is closed under the negation operator \( \neg \), so \( \mathcal{L} \) is an unbounded distributive lattice with negation on which \( \hat{H} \) acts canonically. Moreover the subset \( \hat{X} := \{ \mathcal{M} \in \mathcal{L} \mid \mathcal{M} = \mathcal{M} \} \) of the elements of \( \mathcal{L} \), fixed by the negation operator \( \neg \), is closed under the underlying median operation on the distributive lattice \( \mathcal{L} \)

\[
m(\mathcal{M}_1, \mathcal{M}_2, \mathcal{M}_3) = (\mathcal{M}_1 \cap \mathcal{M}_2) \cup (\mathcal{M}_2 \cap \mathcal{M}_3) \cup (\mathcal{M}_3 \cap \mathcal{M}_1) = (\mathcal{M}_1 \cup \mathcal{M}_2) \cap (\mathcal{M}_2 \cup \mathcal{M}_3) \cap (\mathcal{M}_3 \cup \mathcal{M}_1),
\]

and the action of \( \hat{H} \) on \( \mathcal{L} \) induces an action on the median set \( \hat{X} = (\hat{X}, m) \).

The injective map \( X \to \hat{X}, x \mapsto \mathcal{U}(x) \) identifies the median set \( \mathcal{X} = (X, m) \) with a median (not necessarily convex) subset of \( \hat{X} = (\hat{X}, m) \), i.e. \( m(\mathcal{U}(x), \mathcal{U}(y), \mathcal{U}(z)) = \mathcal{U}(m(x, y, z)) \) for \( x, y, z \in X \).

According to Theorem 1.6., the restriction map \( \text{Spec} \mathcal{L} \to \text{Spec} \hat{X}, \mathcal{P} \to \mathcal{P} \cap \hat{H} \) maps homeomorphically the spectral space \( \text{Spec} \mathcal{L} \) of prime ideals of the distributive lattice with negation \( \mathcal{L} \) onto the spectral space \( \text{Spec} \hat{X} \), the dual of the median set \( \hat{X} \). On the other hand, let us consider the \( \hat{H} \)-equivariant restriction map

\[
\text{Spec} \mathcal{L} \to \mathcal{P}(\hat{H}), \mathcal{P} \to \mathcal{P} \cap \hat{H} := \{ u \in \hat{H} | \mathcal{U}(u) \in \mathcal{P} \}.
\]

First let us show that for all \( \mathcal{P} \in \text{Spec} \mathcal{L} \), \( P := \mathcal{P} \cap \hat{H} \in \mathcal{S} \), i.e. the map above takes values in \( \mathcal{S} \). We have to show that for all \( u \in \hat{H} \), \( q := \mathcal{P}^u \cap X \in \text{Spec} \mathcal{X} \). Let \( x, y \in q \), i.e. \( x, y \in X, x \cup y \in \mathcal{P} \), so \( \mathcal{U}(x), \mathcal{U}(y) \in \mathcal{P}^u := \{ u^{-1} \mathcal{M} | \mathcal{M} \in \mathcal{P} \} \in \text{Spec} \mathcal{L} \). Since \( \mathcal{U}(z) \subseteq \mathcal{U}(x) \cup \mathcal{U}(y) \) for every element \( z \) contained in the cell \([x, y]_\mathcal{X}\) of the median set \( \mathcal{X} \), and \( \mathcal{P}^u \) is an ideal of \( \mathcal{L} \), we deduce that \( \mathcal{U}(z) \in \mathcal{P}^u \) for all \( z \in [x, y]_\mathcal{X} \), whence \([x, y]_\mathcal{X} \subseteq q \) for all \( x, y \in q \). On the other hand, let \( x, y \in X \setminus q \), whence \( \mathcal{U}(x), \mathcal{U}(y) \notin \mathcal{P}^u \). Assuming that \( z \in [x, y]_\mathcal{X} \cap q \), we obtain \( \mathcal{U}(x) \cap \mathcal{U}(y) \subseteq \mathcal{U}(z) \in \mathcal{P}^u \). As \( \mathcal{P}^u \) is a prime ideal of \( \mathcal{L} \), it follows that either \( \mathcal{U}(x) \in \mathcal{P}^u \) or \( \mathcal{U}(y) \in \mathcal{P}^u \), i.e. a contradiction.

Next let us show that the well defined restriction map \( \text{Spec} \mathcal{L} \to \mathcal{S} \) is bijective. For any \( P \in \mathcal{S} \), we denote by \( \text{Id}(P) \) the ideal of \( \mathcal{L} \) generated by the subset \( \{ \mathcal{U}(u) | u \in P \} \). Let us show that \( \text{Id}(P) \) is prime. Let \( \mathcal{M}_1, \mathcal{M}_2 \in \mathcal{L} \) be such that \( \mathcal{M}_1 \cap \mathcal{M}_2 \in \text{Id}(P) \), i.e. \( \mathcal{M}_1 \cap \mathcal{M}_2 \subseteq \bigcup_{i=1}^{n} \mathcal{U}(u_i) \) for some \( u_i \in P, i = 1, \ldots, n \). Obviously, \( P \notin \mathcal{M}_1 \cap \mathcal{M}_2 \), say \( P \notin \mathcal{M}_1 \). As an element of \( \mathcal{L} \), \( \mathcal{M}_1 = \bigcup_{j=1}^{m} \mathcal{U}(F_j) \) for some nonempty finite subsets \( F_j \subseteq \hat{H}, j = 1, m \), with \( m \geq 1 \). Consequently, there exist \( v_j \in F_j \cap P, j = 1, m \), therefore \( \mathcal{M}_1 \subseteq \bigcup_{j=1}^{m} \mathcal{U}(v_j) \in \text{Id}(P) \), whence \( \mathcal{M}_1 \in \text{Id}(P) \), i.e. \( \text{Id}(P) \) is prime as desired.

To conclude that the map \( \text{Spec} \mathcal{L} \to \mathcal{S} \) is bijective, it remains to show that \( P = \)}
Id(\(P\) ∩ \(\hat{H}\)) for \(P \in \mathfrak{S}\), and Id(\(\mathfrak{P} \cap \hat{H}\)) = \(\mathfrak{P}\) for \(\mathfrak{P} \in \text{Spec} \mathfrak{L}\). The inclusions \(\subseteq\) are obvious, while the opposite inclusions follow by straightforward verifications.

The bijection above identifies \(\mathfrak{S}\) with \(\text{Spec} \, \hat{X} \cong \text{Spec} \, \mathfrak{L}\), the dual of the median set \(\hat{X}\), generated (as median set) by its subset \(\{\{u\} \mid u \in \hat{H}\}\), the \(\tilde{H}\)-orbit of \(\tilde{u}\). The \(\tilde{H}\)-equivariant embedding \(S = \text{Spec}(\hat{H}, \tilde{m}) \to \mathfrak{S} \cong \text{Spec} \, \hat{X}\) induces a \(\tilde{H}\)-equivariant surjective morphism of median sets \(\pi : \hat{X} = (\hat{X}, \tilde{m}) \to (\hat{H}, \tilde{m}), \) with \(\pi|_X = 1_X\). In particular, it follows that the action of \(\hat{H}\) on the median set \(\hat{X}\) is free. Notice also that we obtain a canonical \(H\)-equivariant surjective morphism of median sets \(p : \hat{X} \to X\), a retract of the \(H\)-equivariant embedding \(X \to \hat{X}\), by composing \(\pi : \hat{X} \to \hat{H}\) with the folding \(\varphi : \hat{H} \to X\).

Finally, it remains to show that the free action \((\hat{H}, \hat{X})\) extending \((H, X)\) satisfies the universal property (RTUP). Let \((\psi_0, \psi) : (H, X) \to (\hat{H}, \hat{X})\) be a morphism in FAMS such that \(\psi(X) \subseteq \hat{H}\psi(1)\), so we can identify \(\hat{H}\) with the \(\hat{H}\)-orbit \(\hat{H}\psi(1) \subseteq \hat{X}\) and \(\psi(1) \in \hat{X}\) with the neutral element of the group \(\hat{H}\), whence the map \(\psi : X \to \hat{X}\) factors through \(\hat{H}\) and \(\psi_0 = \psi|_H\). As \(X \subseteq \hat{H}\) is stable under the left multiplication with elements of \(H\) and \(\hat{H} = H \ast F\) is the free product of \(H \subseteq X\) and the free group \(F\) with base \(I' \subseteq X\), the map \(\psi\) extends uniquely to the group morphism \(\hat{\psi}_0 : \hat{H} \to \hat{H}\) defined by \(\hat{\psi}_0(h) = \psi(h)\) for \(h \in H\), \(\hat{\psi}_0(i) = \psi(i)\) for \(i \in I'\). To extend the group morphism \(\hat{\psi}_0 : \hat{H} \to \hat{H}\) to the desired morphism \((\psi_0, \hat{\psi}) : (H, \hat{X}) \to (\hat{H}, \hat{X})\) in FAMS it suffices, by duality cf. Theorem 1.6., to define the morphism \(\text{Spec}(\hat{\psi}) : \text{Spec} \, \hat{X} \to \text{Spec} \, X\) over \(\text{Spec} \, X\) in the unique possible way : \(\tilde{P} \in \text{Spec} \, \hat{X} \mapsto \hat{\psi}_0^{-1}(\tilde{P} \cap \tilde{H})\). The latter map is well defined, i.e. \(\hat{\psi}_0^{-1}(\tilde{P} \cap \tilde{H})u \cap \hat{X} = \psi^{-1}(\tilde{P}\hat{\psi}_0(u)) = \psi^{-1}(\hat{\psi}_0(u)^{-1}\tilde{P}) \in \text{Spec} \, X\) for \(u \in \hat{H}, \tilde{P} \in \text{Spec} \, \hat{X}\), since for all \(x \in X\), \(u \in \hat{H}, \tilde{P} \in \text{Spec} \, \hat{X}\), we obtain

\[
x \in \hat{\psi}_0^{-1}(\tilde{P} \cap \tilde{H})u \iff \hat{\psi}_0(ux) = \hat{\psi}_0(u)\psi(x) \in \tilde{P} \iff \\
\psi(x) \in \tilde{P}\hat{\psi}_0(u) \in \text{Spec} \, \hat{X} \iff x \in \psi^{-1}(\tilde{P}\hat{\psi}_0(u)) \in \text{Spec} \, X.
\]

Notice also that the map \(\text{Spec}(\hat{\psi}) : \text{Spec} \, \hat{X} \to \text{Spec} \, \mathfrak{X}\) above is coherent, as required, since for every finite subset \(F \subseteq \hat{H}\), the inverse image of the basic quasicompact open set \(U(F) = \{P \in \mathfrak{S} \mid P \cap F = \emptyset\}\) of the spectral space \(\mathfrak{S} \cong \text{Spec} \, \mathfrak{X}\) is the quasicompact open set \(\{P \in \text{Spec} \, \hat{X} \mid \tilde{P} \cap \tilde{H}(F) = \emptyset\}\) of \(\text{Spec} \, \hat{X}\). This finishes the proof.

One checks easily that the correspondence \((H, X) \mapsto (\hat{H}, \hat{X})\) provided by the statement above extends to an endofunctor \(\text{RTC} : \text{FAMS} \to \text{FAMS}\) (the relatively-transitive closure), together with a natural monomorphism \(\text{rtc} : 1_{\text{FAMS}} \to \text{RTC}\).

5 The transitive closure of a free action on a median set

We are now in position to prove Theorem 3 and its median group theoretic version Theorem 3’ (see the Introduction).

Starting from the endofunctor \(\text{RTC} : \text{FAMS} \to \text{FAMS}\) (the relatively-transitive closure) and the natural monomorphism \(\text{rtc} : 1_{\text{FAMS}} \to \text{RTC}\) as defined in Section 4, we consider the direct system \(\text{RTC} := (\text{RTC}_n)_{n \in \mathbb{N}}\) of endofunctors of FAMS, defined inductively by \(\text{RTC}_0 = 1_{\text{FAMS}}, \text{RTC}_{n+1} = \text{RTC} \circ \text{RTC}_n\), with the connecting natural monomorphisms \(\text{rtc}_n : \text{RTC}_n \to \text{RTC}_{n+1}\), defined by \(\text{rtc}_n = \text{RTC}_n \cdot \text{rtc}\) for \(n \in \mathbb{N}\).
Theorem 5.1. The category \( \text{FTAMS} \) of free and transitive actions on median sets is a reflective full subcategory of \( \text{FAMS} \), i.e. the embedding \( \iota : \text{FTAMS} \to \text{FAMS} \) has a left adjoint \( \text{TC} : \text{FAMS} \to \text{FTAMS} \) (the transitive closure). More precisely, the following assertions hold.

1. The endofunctor \( \iota \circ \text{TC} \) of \( \text{FAMS} \) is the direct limit of the direct system \( \text{RTC} \) of endofunctors of \( \text{FAMS} \).

2. The natural transformation \( \text{TC} \circ \iota \to \text{id}_{\text{FTAMS}} \), the counit of the adjunction, is a natural isomorphism.

3. The natural transformation \( \text{tc} : \text{id}_{\text{FAMS}} \to \iota \circ \text{TC} \), the unit of the adjunction, is a natural monomorphism.

Proof. Let \((H, X)\) be an object of \( \text{FAMS} \), so we may identify \( H \) with the \( H \)-orbit of a base point of the median set \( X \) and the latter with the neutral element 1 of \( H \). Applying step by step the endofunctor \( \text{RTC} : \text{FAMS} \to \text{FAMS} \), we obtain a chain of suitable embeddings

\[
H_0 \to X_0 \to \cdots \to H_n \to X_n \to H_{n+1} \to X_{n+1} \to \cdots,
\]

with \((H_0, X_0) = (H, X), (H_{n+1}, X_{n+1}) = \text{RTC}(H_n, X_n)\) for \( n \in \mathbb{N} \). It follows easily that the union \( \text{TC}(H, X) := \bigcup_{n \in \mathbb{N}} H_n = \bigcup_{n \in \mathbb{N}} X_n \) becomes a median group, and hence an object of \( \text{FTAMS} \) extending \((H, X)\) with the desired universal property (TUP) cf. Theorem 3 from Introduction. The rest of assertions concerning the adjunction between the categories \( \text{FAMS} \) and \( \text{FTAMS} \) follow by straightforward verifications. \qedsymbol

The next example illustrates the complexity of the functorial construction above in the simplest nontrivial case of the free median group with one generator.

Example 5.2. Let \( G = (G, m) \) be a nontrivial median group, and let \( g \in G \setminus \{1\} \).

The median subgroup \( \widehat{G} \) of \( G \) generated by the element \( g \) is the union of the ascending chain \( (G_n)_{n \in \mathbb{N}} \) of subgroups of \( G \), as well as the union of the ascending chain \( (X_n)_{n \in \mathbb{N}} \) of median subsets of \((G, m)\), defined inductively by \( G_0 = 1, X_0 = \{1, g\} \), \( G_{n+1} \) is the subgroup generated by \( X_n \subseteq G \), while \( X_n \) is the median subset generated by \( G_n \subseteq G \) for \( n \geq 1 \). In other words, the free and transitive action of the at most countable group \( G \) on its underlying median set is the transitive closure of the trivial action of \( G_0 = 1 \) on \( X_0 = \{1, g\} \) inside the free and transitive action of \( G \) on its underlying median set.

If \( G = \widehat{G} \) is the free median group with one generator \( g \), i.e. \( G \cong \text{TC}(1, X_0) \), then \( G_1 \cong \mathbb{Z} \), \( G_n \) is a proper factor group of the free group \( G_{n+1} \) for \( n \geq 1 \), so \( G \) is a free group of countable rank, and \( X_{n+1} \) is the median set freely generated by \( G_{n+1} \subseteq X_{n+1} \) over the median set \( X_n \subseteq G_{n+1} \), for \( n \in \mathbb{N} \), in particular, \( X_1 = \text{fms}(\mathbb{Z}) \) is the free median set of countable rank.
