LOGARITHMIC SINGULARITIES OF SCHWARTZ KERNELS
AND LOCAL INVARIANTS OF CONFORMAL AND CR
STRUCTURES

RAPHAÈL PONGE

Abstract. This paper consists of two parts. In the first part we show that in odd dimension, as well as in even dimension below the critical weight (i.e. half the dimension), the logarithmic singularities of Schwartz kernels and Green kernels of conformal invariant pseudodifferential operators are linear combinations of Weyl conformal invariants, i.e., of local conformal invariants arising from complete tensorial contractions of the covariant derivatives of the Lorentz ambient metric of Fefferman-Graham. In even dimension and above the critical weight exceptional local conformal invariants may further come into play. As a consequence, this allows us to get invariant expressions for the logarithmic singularities of the Green kernels of the GJMS operators (including the Yamabe and Paneitz operators). In the second part, we prove analogues of these results in CR geometry. Namely, we prove that the logarithmic singularities of Schwartz kernels and Green kernels of CR invariant Heisenberg pseudodifferential operators give rise to local CR invariants, and below the critical weight are linear combinations of complete tensorial contractions of the covariant derivatives of Fefferman’s Kähler-Lorentz ambient metric. As a consequence, we can obtain invariant descriptions of the logarithmic singularities of the Green kernels of the CR GJMS operators of Gover-Graham (including the CR Yamabe operator of Jerison-Lee).

Introduction

Motivated by the analysis of the singularity of the Bergman kernel of a strictly pseudoconvex domain $D \subset \mathbb{C}^{n+1}$ Fefferman [Fe2] launched the program of determining all local invariants of a strictly pseudoconvex CR structure. This program was subsequently extended to deal with local invariants of other parabolic geometries, including conformal geometry (see [FGH]). Since Fefferman’s seminal paper further progress has been made, especially recently (see, e.g., [Al2], [BEG], [GH], [Hi1], [Hi2]). In addition, there is a very recent upsurge of new conformally invariant Riemannian differential operators (see [Al2], [Ju]).

In this paper we turn to the analysis of the logarithmic singularities of the Schwartz kernels and Green kernels of general invariant pseudodifferential operators in conformal and CR geometry. This connects nicely with results of Hirachi ([Hi1], [Hi2]) on the logarithmic singularities of the Bergman and Szegö kernels on boundaries of strictly pseudoconvex domains.

The main result in the conformal case (Theorem 4.5) asserts that in odd dimension, as well as in even dimension below the critical weight (i.e. half of the dimension), the logarithmic singularities of Schwartz kernels and Green kernels of conformally invariant Riemannian ΨDOs are linear combinations of Weyl conformal invariants, that is, of local conformal invariants arising from tensorial contractions of covariant derivatives of the ambient Lorentz metric of Fefferman-Graham ([FG1], [FG2]). Above the critical weight the description in even dimension involve the ambiguity independent Weyl conformal invariants recently defined by Graham-Hirachi [GH], as well as the exceptional local conformal invariants of Bailey-Gover [BG]. In particular, by specializing this result to the GJMS operators of [GJMS], including the Yamabe and Paneitz operators, we obtain invariant expressions for the logarithmic singularities of the Green kernels of these operators (see Theorem 4.6).

In the CR setting the relevant class of pseudodifferential operators is the class of ΨHDOs introduced by Beals-Greiner [BGr] and Taylor [Tay]. In this context the main result (Theorem 8.6) asserts that the logarithmic singularities of Schwartz kernels and Green kernels of CR invariant ΨHDOs are local CR invariants, and below the critical weight are linear combinations of complete tensorial contractions of covariant derivatives of the curvature of the ambient Čan-Kähler-Lorentz metric of Fefferman [Fe2]. As a consequence this allows us to get invariant expressions for the logarithmic singularities of the Green kernels of the CR GJMS operators of [GG] (see Theorem 8.7).

The proof of the main result in the conformal case is divided into three steps. In the first step we show that, given a ΨDO on a Riemannian manifold transforming conformally under a conformal change of metrics, the logarithmic singularity of its Schwartz kernel, as well as that of its Green kernel when the operator is elliptic, transform conformally under a conformal change of metrics (Proposition 2.1). This result unifies and extends several previous results of Parker-Rosenberg [PR], Gilkey [Gi] and Paycha-Rosenberg [PRo].

The second step is a Riemannian invariant version of the first step. Namely, we show that the logarithmic singularities of Schwartz kernels and Green kernels of Riemannian invariant ΨDOs are local Riemannian invariants, hence can expressed as linear combinations of complete tensorial contractions of covariant derivatives of the curvature tensor (see Proposition 3.5 for the precise statement). This result is very much reminiscent of the Riemannian invariant expression of the coefficients of the heat kernel asymptotics of Laplace-type operators (see [ABP], [Gi]).

In odd dimension, as well as in even dimension below the critical weight, an important result of Bailey-Eastwood-Graham [BEG] shows that all local conformal invariants as linear combinations of Weyl conformal invariants. Recently, in even dimension the remaining cases have been dealt with by Graham-Hirachi [GH]. Therefore, in the final third step, we can simply combine these results with the results of the first two steps to deduce our main results in the conformal case.

Notice that thanks to the Ricci flatness of the ambient metric they are much fewer Weyl conformal invariant than Weyl Riemannian invariants. Therefore, in the third step we get a more precise information on the forms of the logarithmic singularities at stake than the Riemannian invariant expressions provided by the second step.
Next, the proof of the main result in the CR setting follows a similar pattern. First, we prove that, given a $\Psi_H$DO on a contact manifold which transforms conformally under a conformal change of contact form, the logarithmic singularities of its Schwartz kernel and its Green kernel (when the operator is hypoelliptic) transform conformally under a conformal change of contact form (see Proposition [6.1]). This extends a previous result of N.K. Stanton [St].

In the second step we deal with the logarithmic singularities of pseudohermitian invariant $\Psi_H$DOs (these objects are defined in Section 7). More precisely, we show that the logarithmic singularities of the Schwartz kernels and the Green kernels of pseudohermitian invariant $\Psi_H$DOs are local pseudohermitian invariants (see Proposition [7.9]). Therefore these logarithmic singularities appear as universal linear combinations of complete tensorial contractions of covariant derivatives of the (pseudohermitian) curvature tensor and of the torsion tensor of the Tanaka-Webster connection.

Similarly to a conformally invariant Riemannian $\Psi$DO, a CR invariant $\Psi_H$DO is a pseudohermitian invariant $\Psi_H$DOs that transforms conformally under a conformal change of contact form. Furthermore, we know from Fefferman [Fe2] and Bailey-Eastwood-Graham [BEG] that any local CR invariant of weight less than or equal to the critical weight is linear combination of Weyl CR invariants. Combining this with the previous steps allows us to prove the main results in the CR case.

The first and third steps in the CR case are carried along similar lines as that of the corresponding steps in the conformal case. There are some technical issues with the second step because we need to introduce definitions of local pseudohermitian invariant and of pseudohermitian invariant $\Psi_H$DOs in such way that the former is equivalent to the usual definition of a local pseudohermitian invariant and both definitions are suitable for working with the Heisenberg calculus. In particular, it is important to take into account the tangent structure of a strictly pseudoconvex CR manifold, in which the Heisenberg group comes into play. The bulk of this step then is to prove all the properties of local pseudohermitian invariants and pseudohermitian invariant $\Psi_H$DOs that are needed in order to prove that the logarithmic singularities of the Schwartz kernels and the Green kernels of the latter do give rise to local pseudohermitian invariants. More generally, the arguments used in this step pave the way for proving that various local invariants attached to pseudohermitian invariant $\Psi_H$DOs (e.g. local zeta function invariants) give rise to local pseudohermitian invariants.

Finally, it is believed that by making use of the ambient metric construction of the GJMS operators in [GJMS] we could compute the logarithmic singularities of these operators in the conformal case, as well as in the CR case. It is conjectured that there should be related in a somewhat explicit way to the coefficients of the heat kernel asymptotics of the Laplace operator, which has been thoroughly studied (see [Gi] and the references therein). We hope to report more on this in a subsequent paper.

The paper is organized as follows.

In Section 1 we recall how the logarithmic singularity of a $\Psi$DO gives rise to a well defined density. We then explain its connection with the noncommutative residue trace of Wodzicki and Guillemin.

In Section 2 we show that the conformal invariance of the logarithmic singularities of the Schwartz kernels and Green kernels of conformally invariant $\Psi$DOs.
In Section 3 we show that the logarithmic singularities of the Schwartz kernels and Green kernels of Riemannian invariant ΨDOs are local Riemannian invariants.

In Section 4 we prove that the logarithmic singularities of the Schwartz kernels and Green kernels of conformally invariant ΨDOs are linear combinations of the local conformal invariants in the sense of Fefferman’s program. In particular, this leads us to invariant expressions for the logarithmic singularities of the Green kernels of the GJMS operators.

In Section 5 we recall some important facts about Ψ_HDOs and their logarithmic singularities.

In Section 6, we prove the contact invariance of the Schwartz kernels and Green kernels of contact invariant Ψ_HDOs.

In Section 7, we define pseudohermitian invariant Ψ_HDOs and prove that their Schwartz kernels and Green kernels give rise to local pseudohermitian invariants.

In Section 8, we prove that the Schwartz kernels and Green kernels of CR invariant Ψ_HDOs are linear combinations of Weyl CR invariants, which allows us to get invariant expressions for the Green kernels of the CR GJMS operators.

Acknowledgements. I am very grateful to Pierre Albin, Charles Fefferman, Robin Graham, Kengo Hirachi and Sidney Webster for helpful and stimulating discussions related to the subject matter of this paper. In addition, I wish to thank for their hospitality the University of Tokyo and the University of California at Berkeley where part of this paper was written.

1. Pseudodifferential Operators and the Logarithmic Singularities of their Schwartz Kernels

In this section we recall some definitions and properties about ΨDOs and the logarithmic singularities of the Schwartz kernels of ΨDOs.

First, given an open subset $U \subset \mathbb{R}^n$ the symbols on $U \times \mathbb{R}^n$ are defined as follows.

Definition 1.1. 1) $S_m(U \times \mathbb{R}^n)$, $m \in \mathbb{C}$, is the space of functions $p(x, \xi)$ contained in $C^\infty(U \times \mathbb{R}^n \setminus \emptyset)$ such that $p(x, t\xi) = t^m p(x, \xi)$ for any $t > 0$.

2) $S^m(U \times \mathbb{R}^n)$, $m \in \mathbb{C}$, consists of functions $p \in C^\infty(U \times \mathbb{R}^n)$ with an asymptotic expansion $p \sim \sum_{j \geq 0} p_{m-j}(x, \xi)$, $p_k \in S_k(U \times \mathbb{R}^n)$, in the sense that, for any integer $N$, any compact $K \subset U$ and any multi-orders $\alpha, \beta$, there exists a constant $C_{NK\alpha\beta} > 0$ such that, for any $x \in K$ and any $\xi \in \mathbb{R}^{d+1}$ so that $|\xi| \geq 1$, we have

\begin{equation}
|\partial^{\alpha}_x \partial^{\beta}_\xi (p - \sum_{j < N} p_{m-j}(x, \xi))| \leq C_{NK\alpha\beta} |\xi|^{\Re m - \langle \beta \rangle - N}.
\end{equation}

Given a symbol $p \in S^m(U \times \mathbb{R}^n)$ we let $p(x, D)$ be the continuous linear operator from $C^\infty_c(U)$ to $C^\infty(U)$ such that

\begin{equation}
p(x, D)u(x) = (2\pi)^{-n} \int e^{ix \cdot \xi} p(x, \xi) \hat{u}(\xi) d\xi \quad \forall u \in C^\infty_c(U).
\end{equation}

Let $M^n$ be a manifold and let $\mathcal{E}$ be a vector bundle over $M$. We define ΨDOs on $M$ acting on the sections of $\mathcal{E}$ as follows.

Definition 1.2. $\Psi^m(M, \mathcal{E})$, $m \in \mathbb{C}$, consists of continuous operators $P$ from $C^\infty_c(M, \mathcal{E})$ to $C^\infty(M, \mathcal{E})$ such that:

(i) The Schwartz kernel of $P$ is smooth off the diagonal;
(ii) In any trivializing local coordinates the operator $P$ can be written as

$$P = p(x, D) + R,$$

where $p$ is a symbol of order $m$ and $R$ is a smoothing operator.

We can give a precise description of the singularity of the Schwartz kernel of a $\Psi DOs$ near the diagonal and, in fact, the general form of these singularities can be used to characterize $\Psi DOs$ (see, e.g., [Hö2], [Mc], [BG3]). In particular, if $P : C^\infty_c(M, \mathcal{E}) \to C^\infty(M, \mathcal{E})$ if a $\Psi DO$ of integer order $m \geq -n$, then in local coordinates its Schwartz kernel $k_P(x, y)$ has a behavior near the diagonal $y = x$ of the form

$$k_P(x, y) = \sum_{-(m+n) \leq j \leq -1} a_j(x, x - y) - c_P(x) \log |x - y| + O(1),$$

where $a_j(x, y) \in C^\infty(U \times (\mathbb{R}^n \setminus 0))$ is homogeneous of degree $j$ in $y$ and we have

$$c_P(x) = \frac{1}{(2\pi)^n} \int_{S^{n-1}} p_{-n}(x, \xi) d^{n-1}\xi,$$

where $p_{-n}(x, \xi)$ is the symbol of degree $-n$ of $P$.

It seems to have been first observed by Connes-Moscovici [CMo] (see [GVF], [Po4]) for detailed proofs) that the coefficient $c_P(x)$ makes sense globally on $M$ as a 1-density with values in $\text{End} \mathcal{E}$, i.e., it defines an element of $C^\infty(M, |\Lambda|(M) \otimes \text{End} \mathcal{E})$ where $|\Lambda|(M)$ is the bundle of 1-densities on $M$.

In the sequel we refer to the density $c_P(x)$ as the logarithmic singularity of the Schwartz kernel of $P$.

If $P$ is elliptic, then we shall call Green kernel for $P$ the Schwartz kernel of a parametrix $Q \in \Psi^{-m}(M, \mathcal{E})$ for $P$. Such a parametrix is uniquely defined only modulo smoothing operators, but the singularity near the diagonal of the Schwartz kernel of $Q$, including the logarithmic singularity $c_Q(x)$, does not depend on the choice of $Q$.

**Definition 1.3.** If $P \in \Psi^m(M, \mathcal{E})$, $m \in \mathbb{Z}$, is elliptic, then the Green kernel logarithmic singularity of $P$ is the density

$$\gamma_P(x) := c_Q(x),$$

where $Q \in \Psi^{-m}(M, \mathcal{E})$ is any given parametrix for $P$.

Next, because of (1.3), the density $c_P(x)$ is related to the noncommutative residue trace of Wodzicki ([Wo1], [Wo3]) and Guillemin ([Gu1]) as follows.

Let $\Psi^{\text{int}}(M, \mathcal{E}) = \cup_{m < -n} \Psi^m(M, \mathcal{E})$ denote the class of $\Psi DOs$ whose symbols are integrable with respect to the $\xi$-variable. If $P$ is a $\Psi DO$ in this class then the restriction to the diagonal of its Schwartz kernel $k_P(x, x)$ defines a smooth $\text{End} \mathcal{E}$-valued density $k_p(x, x)$. Therefore, if $M$ is compact then $P$ is trace-class on $L^2(M, \mathcal{E})$ and we have

$$\text{Trace } P = \int_M k_P(x, x).$$

In fact, the map $P \to k_P(x, x)$ admits an analytic continuation $P \to t_P(x)$ to the class $\Psi^{\text{hol}}(M, \mathcal{E})$ of non-integer $\Psi DOs$, where analyticity is meant with respect to holomorphic families of $\Psi DOs$ as in [Gu2] and [KV]. Furthermore, if $P \in \Psi^{\text{hol}}(M, \mathcal{E})$ and if $(P(z))_{z \in \mathbb{C}}$ is a holomorphic family of $\Psi DOs$ such that $\text{ord} P(z) = \text{ord } P + z$
and \( P(0) = P \). Then the map \( z \to t_{P(z)}(x) \) has at worst a simple pole singularity at \( z = 0 \) in such way that

\[
(1.8) \quad \text{Res}_{z=0} t_{P(z)}(x) = -c_P(x).
\]

Suppose now that \( M \) is compact. Then the noncommutative residue is the linear functional on \( \Psi^\mathbb{Z}(M, \mathcal{E}) \) defined by

\[
(1.9) \quad \text{Res} P := \int_M \text{tr}_\mathcal{E} c_P(x) \quad \forall P \in \Psi^{\mathbb{C}\mathbb{Z}}(M, \mathcal{E}).
\]

Thanks to (1.5) this definition agrees with the usual definition of the noncommutative residue. Moreover, by using (1.8) we see that if \((P(z))_{z \in \mathbb{C}}\) is a holomorphic family of \( \Psi \)-DOs such that \( \text{ord} P(z) = \text{ord} P + z \) and \( P(0) = P \), then the map \( z \to \text{Trace} P(z) \) has an analytic extension to \( \mathbb{C} \setminus \mathbb{Z} \) with at worst a simple pole near \( z = 0 \) in such way that

\[
(1.10) \quad \text{Res} P = -\text{Res}_{z=0} \text{TR} P(z).
\]

Using this it is not difficult to see that the noncommutative residue is a trace on \( \Psi^\mathbb{Z}(M, \mathcal{E}) \). Wodzicki [Wo2] even proved that this is the unique trace up to constant multiple when \( M \) is connected.

Finally, let \( P : C^\infty(M, \mathcal{E}) \to C^\infty(M, \mathcal{E}) \) be a \( \Psi \)-DO of integer order \( m \geq 0 \) with a positive principal symbol. For \( t > 0 \) we let \( k_t(x, y) \) denote the Schwartz kernel of \( e^{-tP} \). Then \( k_t(x, y) \) is a smooth kernel and as \( t \to 0^+ \) we have

\[
(1.11) \quad k_t(x, x) \sim t^{-\frac{n}{2}} \sum_{j \geq 0} t^{\frac{m}{2}} a_j(P)(x) + \log t \sum_{j \geq 0} t^{j} b_j(P)(x),
\]

where we further have \( a_{j+1}(P)(x) = b_j(P)(x) = 0 \) for any \( j = 0, 1, \ldots \) when \( P \) is a differential operator (see, e.g., [Gi], [Gr]).

By making use of the Mellin Formula we can explicitly relate the coefficients of the above heat kernel asymptotics to the singularities of the local zeta function \( t_{P-\sigma}(x) \) (see, e.g., [Wo2] 3.23). In particular, if for \( j = 0, \ldots, n-1 \) we set \( \sigma_j = \frac{m-j}{m} \) then we have

\[
(1.12) \quad mc_{P-\sigma_j}(x) = \Gamma(\sigma_j)^{-1} a_j(P)(x).
\]

The above equalities provide us with an immediate connection between the Green kernel logarithmic singularity of \( P \) and the heat kernel asymptotics (1.11). Indeed, as the partial inverse \( P^{-1} \) is a parametrix for \( P \) in \( \Psi^{-m}(M, \mathcal{E}) \), setting \( j = n - m \) in (1.12) gives

\[
(1.13) \quad a_{n-m}(P)(x) = mc_{P-1}(x) = m \gamma_P(x).
\]

2. Conformal Invariance of Logarithmic Singularities of \( \Psi \)-DOs

In this section we will prove that the logarithmic singularities of conformally invariant \( \Psi \)-DOs on a given Riemannian manifold \((M^n, g)\) transform conformally under conformal changes of metric.

Throughout this section we let \((M^n, g)\) be a Riemannian manifold. The first historic instances of conformally invariant operator were the Dirac and Yamabe operators.
Proof. Let $\mathcal{E}$ denote a vector bundle over $M$ and we let $\mathcal{G}$ be the class of Riemannian metrics on $M$ that are conformal multiples of $g$.

Let $(P_g)_{g \in \mathcal{G}} \subset \Psi^m(M, \mathcal{E})$ be a family of ΨDOs of integer order $m$ so that there are real numbers $w$ and $w'$ in such way that, for any $f \in C^\infty(M, \mathbb{R})$, we have

$$P_{e^{w}f} = e^{w'} P_{g} e^{-w} \mod \Psi^{-\infty}(M, \mathcal{E}).$$

**Proposition 2.1.** 1) If $m \geq -n$, then

$$c_{P_{e^{w}f}}(x) = e^{-(w-w')f(x)}c_{P_{g}}(x) \quad \forall f \in C^\infty(M, \mathbb{R}).$$

2) Assume that $P_g$ is elliptic and we have $0 \leq m \leq n$, then

$$\gamma_{P_{e^{w}f}}(x) = e^{-(w'-w)f(x)}\gamma_{P_{g}}(x) \quad \forall f \in C^\infty(M, \mathbb{R}).$$

**Proof.** Let $f \in C^\infty(M, \mathbb{R})$, set $\tilde{g} = e^{f}g$ and let $k_{P_{g}}(x,y)$ and $k_{P_{g}}(x,y)$ denote the respective Schwartz kernels of $P_{g}$ and $P_{g}$. It follows from (2.6) that near the diagonal $y = x$ we have

$$k_{P_{g}}(x,y) = e^{w'f(x)}k_{P_{g}}(x,y)e^{-w'f(y)} + O(1).$$
Let $U \subset \mathbb{R}^n$ be an open of local coordinates. By (1.4) the kernel $k_{P_g}(x, y)$ has a behavior near the diagonal of the form
\begin{equation}
(2.10) \quad k_{P_g}(x, y) = \sum_{-m \leq n \leq j \leq -1} a_j(x, y) - c_{P_g}(x) \log |x - y| + O(1),
\end{equation}
where $a_j(x, y) \in C^\infty(U \times (\mathbb{R}^n \setminus 0))$ is homogeneous of degree $j$ with respect to $y$. Combining this with (2.9) then gives
\begin{equation}
(2.11) \quad k_{P_g}(x, y) = \sum_{-m \leq n \leq j \leq -1} b(x, y) a_j(x, y) - c_{P_g}(x) b(x, y) \log |x - y| + O(1),
\end{equation}
where we have set $b(x, y) = e^{-wf(y)+w'f(x)}$.

The Taylor expansion of $b(x, y)$ near $y = x$ is of the form
\begin{equation}
(2.12) \quad b(x, y) = \sum_{|\alpha| < m} (y - x)^\alpha b_\alpha(x) + \sum_{|\alpha| = m} (y - x)^\alpha r_\alpha(x, y),
\end{equation}
where we have set $b_\alpha(x) = \frac{1}{\alpha!} \partial^\alpha_b b(x, x)$, and the functions $r_\alpha(x, y)$ are smooth near $y = x$. Using this we obtain
\begin{equation}
(2.13) \quad b(x, y) a_j(x, y) = \sum_{|\alpha| + j \leq -1} b_\alpha(x)(y - x)^\alpha a_j(x, y) + O(1),
\end{equation}
where each term $b_\alpha(x)(y - x)^\alpha a_j(x, y)$ is homogeneous in $y$ of degree $|\alpha| + j \leq -1$.

Moreover, as we have $(x - y)^\alpha \log |x - y| = O(1)$ for any multi-order $\alpha \neq 0$, from (2.12) we also get
\begin{equation}
(2.14) \quad b(x, y) \log |x - y| = b(x, x) \log |x - y| + O(1) = e^{-(w-w')f(x)} \log |x - y| + O(1).
\end{equation}

Combining (2.11) with (2.13) and (2.14) shows that $k_{P_g}(x, y)$ has a behavior near the diagonal of the form
\begin{equation}
(2.15) \quad k_{P_g}(x, y) = \sum_{-(m+n) \leq |\alpha| + j \leq -1} b_\alpha(x)(y - x)^\alpha a_j(x, y) - c_{P_g}(x) e^{-(w-w')f(x)} \log |x - y| + O(1).
\end{equation}
Comparing this to (1.4) yields the equality $c_{P_g}(x) = e^{-(w-w')f(x)} c_{P_g}(x)$.

Now, assume that $P_g$ is elliptic and we have $m \leq n$. Let $Q_g$ (resp. $Q_\delta$) be a parametrix in $\Psi^{m}(M, \mathcal{E})$. Let $Q_g$ (resp. $P_g$) be parametrix in $\Psi^{m}(M, \mathcal{E})$. Thanks to (2.3) we have
\begin{equation}
(2.16) \quad P_g e^{w'f} Q_g e^{-w'f} = e^{w'f} P_g e^{-w'f} = 1 \quad \text{mod } \Psi^{-\infty}(M, \mathcal{E}).
\end{equation}
Multiplying the right-hand and left-hand sides by $Q_\delta$ gives
\begin{equation}
(2.17) \quad Q_\delta P_g e^{w'f} Q_\delta e^{-w'f} = e^{w'f} Q_\delta e^{-w'f} \quad \text{mod } \Psi^{-\infty}(M, \mathcal{E}).
\end{equation}
We then can apply the first part of the proof to get $c_{Q_\delta}(x) = e^{-(w-w')f(x)} c_{P_g}(x)$. The proof is now complete.

The above result unifies and extend several previous results of conformal invariance of densities associated to conformally invariant operators.

First, in [PR] Parker-Rosenberg proved the conformal invariance on a compact manifold of the Green kernel of the Yamabe operator $\Box_g$ (i.e. the Schwartz kernel of $\Box_g^{-1}$). In this setting the singularity near the diagonal of the Green kernel is derived from the knowledge of the off-diagonal small time asymptotics for the heat kernel of $\Box_g$. Moreover, the logarithmic singularity is described in the form $-c(x) \log d(x, y)$,
where \( d(x, y) \) is the Riemannian distance. Since in local coordinates \( \log \frac{d(x, y)}{|x-y|} \) is bounded near \( y = x \) this description of the logarithmic singularity is the same as that provided by (1.4). Therefore, we see that Proposition 2.1 allows us to recover Parker-Rosenberg’s result.

In fact, in [PR] the coefficient \( c(x) \) in the logarithmic singularity \(-c(x) \log d(x, y)\) was identified with the coefficient \( a_{n-2}(\square_g)(x) \) of \( t^{-1} \) in the heat kernel asymptotics (1.11) for \( \square_g \). This allowed Parker-Rosenberg to prove the conformal invariance of \( a_{n-2}(\square_g)(x) \). Subsequently, Gilkey [Gi, Thm. 1.9.4] proved the conformal invariance of the coefficient \( a_{n-m}(P_g)(x) \) of \( t^{-1} \) in the heat kernel asymptotics for a conformally invariant selfadjoint elliptic differential operator \( P_g \) of order \( m \) with positive principal symbol on a compact Riemannian manifold. Thanks to (1.13) we have \( a_{n-m}(P_g)(x) = m\gamma P_{\mu}(x) \), so Proposition 2.1 also allows us to recover Gilkey’s result.

Recently Paycha-Rosenberg [PRo] extended Gilkey’s result to \( \PsiDOs \) and proved the conformal invariance of noncommutative residue densities of conformally invariant \( \PsiDOs \). The arguments were based on variational formulas for zeta functions of elliptic \( \PsiDOs \), so the result was stated for compact manifold and for an elliptic conformally invariant \( \PsiDOs \). For instance, let \( n \geq 3 \), datum on any Riemannian manifold \((M^n, g)\) of a function \( T_g \in C^\infty(M) \) such that:

\[ L_{x,y} Q_{\mu}^{(k)}(x) = e^{2\gamma - 2\omega'} f \mu \cdot Q_{\mu}^{(k)}(x) \forall f \in C^\infty(M, R). \]

Furthermore, if we choose \( L_g \) to be non-elliptic, then \( L_g Q_{\mu}^{(k)}(x) \) is not elliptic and we really need to use Proposition 2.1 to prove that:

\[ c_{L_{x,y} Q_{\mu}^{(k)}}(x) = e^{2\gamma - 2\omega'} f c_{L_{x,y} Q_{\mu}^{(k)}}(x) \forall f \in C^\infty(M, R). \]

### 3. Logarithmic Singularities of Riemannian Invariant \( \PsiDOs \)

In this section we shall prove that the logarithmic singularities of Riemannian invariant \( \PsiDOs \) are local Riemannian invariants.

Let \( M_+(R) \) denote the open subset of \( M_+(R) \) consisting of positive definite matrices. Following [ABP] we call scalar local Riemannian invariant of weight \( w \), \( w \in Z \), datum on any Riemannian manifold \((M^n, g)\) of a function \( T_g \in C^\infty(M) \) such that:
- There exist finitely many functions \( a_{\alpha\beta} \in C^\infty(M_n(\mathbb{R}_+)) \) such that in any local coordinates we can write \( \mathcal{I}_g(x) = \sum a_{\alpha\beta}(g(x))(\partial^\alpha g(x))\beta \).

- We have \( \mathcal{I}_{tg}(x) = t^{-w} \mathcal{I}_g(x) \) for any \( t > 0 \).

It follows from the invariant theory developed by Atiyah-Bott-Patodi [ABP] (see also [FG]) that any local Riemannian invariant is a linear combination of complete contractions of the covariant derivatives of the curvature tensor.

Notice also that the above definition continue to make sense for manifolds equipped with a nondegenerate metric of nonpositive signature, provided we replace \( M_+(\mathbb{R})_+ \) by the subset of nondegenerate selfadjoint matrix of the corresponding signature. Following the convention of [FG1] we shall continue to call local Riemannian invariants such invariants.

Let \( R_{ijkl} = (R(\partial_i, \partial_j)\partial_k, \partial_l) \) denote the components of the curvature tensor of \((M, g)\). We will use the metric \( g = (g_{ij}) \) and its inverse \( g^{-1} = (g^{ij}) \) to lower and raise indices. For instance, the Ricci tensor is \( \rho_{jk} := R_{ij}k^i = g^{il}R_{ijkl} \) and the scalar curvature is \( \kappa_g := \rho_{ij}^j = g^{ij}\rho_{ij}^i \).

All the scalar local Riemannian invariants of weight 1 are constant multiples of \( \kappa_g \), and those of weight 2 are linear combinations of the following invariants:

\[
|R|^2_g := R_{ijkl}R_{ijkl}, \quad |\rho|^2_g := \rho_{ij}\rho_{jk}, \quad |\kappa_g|^2, \quad \Delta_g \kappa_g.
\]

Next, for \( m \in \mathbb{C} \) we let \( S_m(M_n(\mathbb{R}_+ \times \mathbb{R}^2) \) denote the space of functions \( a(g, \xi) \) in \( C^\infty(M_n(\mathbb{R}_+ \times (\mathbb{R}^n \setminus 0)) \) such that we have \( a(g, t\xi) = t^m a(g, \xi) \) for any \( t > 0 \).

**Definition 3.1.** A Riemannian invariant \( \Psi DO \) of order \( m \) and weight \( w \) is the datum on any Riemannian manifold \((M^n, g)\) of an operator \( P_g \in \Psi^m(M) \) so that:

(i) For \( j = 0, 1, \ldots \) there exist finitely many symbols \( a_{j\alpha\beta} \in S_{m-j}(M_n(\mathbb{R}_+ \times \mathbb{R}^2) \) such that in any local coordinates \( P_g \) has symbol \( p_g(x, \xi) \sim \sum_{j \geq 0} p_g_{m-j}(x, \xi) \), where

\[
p_{g,m-j}(x, \xi) = \sum_{\alpha,\beta} (\partial^\alpha g(x))\beta a_{j\alpha\beta}(g(x), \xi);
\]

(ii) For any \( t > 0 \) we have \( P_{tg} = t^{-w} P_g \) modulo \( \Psi^{-\infty}(M) \).

In addition, we say that \( P \) is admissible if in (3.2) we can take \( a_{0\alpha\beta} \) to be zero for \( (\alpha, \beta) \neq 0 \).

**Remark 3.2.** In (ii) we require to have \( P_{tg} = t^{-w} P_g \) modulo smoothing operators, rather than to have an actual equality, so that if we replace \( P_g \) by a properly supported \( \Psi DO \) that agrees with \( P_g \) modulo a smoothing operator, then we get a Riemannian invariant \( \Psi DO \) with same symbol. This way we can compose Riemannian invariant \( \Psi DOs \). This is totally innocuous when we consider differential operators, because two differential operators that differ by a smoothing operator agree.

**Proposition 3.3.** Let \( P_g \) be a Riemannian invariant \( \Psi DO \) of order \( m \) and weight \( w \), let \( Q_g \) be a Riemannian \( \Psi DO \) of order \( m' \) and weight \( w' \), and suppose that \( P_g \) or \( Q_g \) is properly supported. Then \( P_g Q_g \) is a Riemannian invariant \( \Psi DO \) of order \( m + m' \) and weight \( w + w' \).

**Proof.** First, the operator \( P_g Q_g \) is a \( \Psi DO \) of order \( m + m' \) and for any \( t > 0 \) we have \( P_{tg} Q_g = t^{-(w+w')} P_g Q_g \) modulo \( \Psi^{-\infty}(M) \).

Next, let \( p_g(x, \xi) \sim \sum p_{g,m-j}(x, \xi) \) and let \( q_g(x, \xi) \sim \sum q_{g,m'-j}(x, \xi) \) be the respective symbols of \( P_g \) and \( Q_g \) in local coordinates. Then it is well-known (see,
e.g., [H62]) that the symbol \( r_g(x, \xi) \sim \sum r_{g,m'-j}(x, \xi) \) of \( P_g Q_g \) is such that we have \( r_g(x, \xi) \sim \sum \frac{1}{\alpha!} \partial_{\xi}^\alpha p_g(x, \xi) D_x^\alpha q_g(x, \xi) \). Thus,

\[
(3.3) \quad r_{g,m+m'-j}(x, \xi) = \sum_{|\alpha|+k+l=j} \frac{1}{\alpha!} \partial_{\xi}^\alpha p_g m-k(x, \xi) D_x^\alpha q_{g,m-l}(x, \xi).
\]

By assumption \( p_g(x, \xi) \) and \( q_g(x, \xi) \) satisfy the condition (i) of Definition [3.1]. Therefore, using (3.3) it is not difficult to check that so does \( r_g(x, \xi) \). Hence \( P_g Q_g \) is a Riemannian invariant \( \Psi DO \) of weight \( w+w' \).

\[ \text{□} \]

**Proposition 3.4.** Let \( P_g \) be Riemannian invariant \( \Psi DO \) of order \( m \) and weight \( w \) which is elliptic and is admissible in the sense of Definition [3.1]. For each Riemannian manifold \((M^n, g)\) let \( Q_g \in \Psi^{-m}(M, \xi) \) be a parametrix for \( P \). Then \( Q_g \) is a Riemannian invariant \( \Psi DO \) of weight \(-w\).

**Proof.** First, without any loss of generality we may assume \( Q_g \) to be properly supported. Let \( t > 0 \). As \( P_g = t^{-w} P_g \) modulo \( \Psi^{-\infty}(M) \) we see that \( t^w Q_g \) is a parametrix for \( P_g \), hence it agrees with \( Q_{tg} \) modulo \( \Psi^{-\infty}(M) \).

Next, since \( P_g \) is admissible there exists \( a_m \in S_m(M_n(\mathbb{R}^n) \times \mathbb{R}^n) \) such that in any given local coordinates the principal symbol of \( P_g \) is \( p_m(x, \xi) = a_m(g(x), \xi) \). The fact that \( P_g \) is elliptic then implies that, for any Riemannian manifold \((M^n, g)\) and for \( x \) in the range of the given local coordinates, we have \( a_m(g(x), \xi) \neq 0 \) for any \( \xi \neq 0 \). Since any matrix \( g \in M_n(\mathbb{R}^n) \) defines a Riemannian metric on \( \mathbb{R}^n \), we see that \( a_m(g, \xi) \) is an invertible symbol in \( S_m(M_n(\mathbb{R}^n) \times \mathbb{R}^n) \).

Now, let \( p \sim \sum p_{g,m-j}(x, \xi) \) and \( q(x, \xi) \sim \sum q_{g,m-j}(x, \xi) \) be the respective symbols of \( P_g \) and \( Q_g \) in local coordinates. As we have \( Q_g P_g = 1 \) modulo \( \Psi^{-\infty}(M) \), using (3.3) we get

\[
(3.4) \quad q_{m} p_{g,m} = 1, \quad \sum_{|\alpha|+k+l=j} \frac{1}{\alpha!} \partial_{\xi}^\alpha q_{m-k} D_x^\alpha p_{g,m-l} = 0 \quad j \geq 1.
\]

Therefore, we obtain

\[
(3.5) \quad q_{m}(x, \xi) = p_{g,m}(x, \xi)^{-1} = a_m(g(x), \xi)^{-1},
\]

\[
(3.6) \quad q_{m-j}(x, \xi) = a_m(g(x), \xi)^{-1} \sum_{|\alpha|+k+l=j} \frac{1}{\alpha!} \partial_{\xi}^\alpha q_{m-k}(x, \xi) D_x^\alpha p_{m-l}(x, \xi) \quad j \geq 1.
\]

By induction we then can show that for \( j = 0, 1, \ldots \) the symbol \( q_{m-j}(x, \xi) \) can be expressed as a universal expression of the form (3.2). This completes the proof that \( Q_g \) is a Riemannian invariant \( \Psi DO \) of weight \(-w\). \[ \text{□} \]

In the sequel for any top-degree form \( \eta \) on \( M \) we let \( |\eta| \) denote the corresponding 1-density (or measure) defined by \( \eta \). For instance, if \( v_g(x) := \sqrt{g(x)} dx^1 \wedge \cdots \wedge dx^n \) is the Riemannian volume form, then the Riemannian density is \( |v_g(x)| \). In local coordinates we have \( |v_g(x)| = \sqrt{g(x)} dx \), where \( dx = \sqrt{g(x)} dx^0 \wedge \cdots \wedge dx^n \) is the Lebesgue measure of \( \mathbb{R}^n \).

**Proposition 3.5.** Let \( P_g \) be a Riemannian invariant \( \Psi DO \) of order \( m \) and weight \( w \).

1) The logarithmic singularity \( c_{P_g}(x) \) is of the form

\[
(3.7) \quad c_{P_g}(x) = \mathcal{I}_{P_g}(x)|v_g(x)|,
\]

where \( \mathcal{I}_{P_g}(x) \) is a local Riemannian invariant of weight \( \frac{w}{2} + w \).
2) Assume that $P_g$ is elliptic and is admissible in the sense of Definition 3.4. Then the Green kernel logarithmic singularity of $P$ takes the form

$$\gamma_{P_g}(x) = I_{P_g}(x)|v_g(x)|,$$

where $I_{P_g}(x)$ is a local Riemannian invariant of weight $\frac{w}{2} - w$.

Proof. Let us write $c_{P_g}(x) = I_g(x)|v_g(x)|$. Let $t > 0$. Since $P_g$ and $t^{-w}P_g$ agree up to a smoothing operator we have $t^{-w}c_{P_g}(x) = c_{P_{tg}}(x)$. As $dv_{tg}(x) = t^{\frac{w}{2}}|v_g(x)|$ we see that $I_{P_{tg}}(x) = t^{-\left(\frac{w}{2} + w\right)}I_{P_g}(x)$.

On the other hand, since $P_g$ is a Riemannian invariant $\Psi$DO there exist finitely many symbols $a_{\alpha\beta} \in S_{m-3}(M_n(\mathbb{R})_+ \times \mathbb{R}^n)$ such that in any local coordinates the symbol of degree $-n$ of $P_g$ is $p_{-n}(x,\xi) = \sum (\partial^n g(x))^\beta a_{\alpha\beta}(g(x),\xi)$. By (3.13) in local coordinates we have $c_{P_g}(x) = I_g(x)\sqrt{g(x)}dx = (2\pi)^{-n}(\int_{S^{n-1}} p_{-n}(x,\xi) d^{n-1}\xi)dx$.

Thus,

$$I_g(x) = \frac{1}{\sqrt{g(x)}} \sum (\partial^n g(x))^\beta A_{\alpha\beta}(g(x)),$$

where $A_{\alpha\beta}$ is the smooth function on $M_n(\mathbb{R})_+$ defined by

$$A_{\alpha\beta}(g) := (2\pi)^{-n}\int_{S^{n-1}} a_{\alpha\beta}(g,\xi) d^{n-1}\xi \quad \forall g \in M_n(\mathbb{R})_+.$$

Since the expression (3.9) of $I_g(x)$ holds in any local coordinates this proves that $I_g(x)$ is a local Riemannian invariant.

Finally, suppose that $P_g$ is elliptic and is admissible. For each Riemannian manifold $(M^n, g)$ let $Q_g \in \Psi^{-m}(M)$ be a parametrix for $P_g$. Then the Green kernel logarithmic singularity $\gamma_{Q_g}(x)$ agrees with $c_{Q_g}(x)$ and Proposition 3.4 tells us that $Q_g$ is a Riemannian invariant $\Psi$DO of weight $-w$. Therefore, it follows from the first part of the proposition that $\gamma_{P_g}(x)$ is of the form $\gamma_{P_g}(x) = I_{P_g}(x)|v_g(x)|$, where $I_{P_g}(x)$ is a local Riemannian invariant of weight $\frac{w}{2} - w$. \qed

4. Logarithmic Singularities and Local Conformal Invariants

In this section we shall make use of the program of Fefferman in conformal geometry to give a precise form of the logarithmic singularities of conformally invariant Riemannian $\Psi$DOs.

4.1. Conformal invariants and Fefferman’s program. Motivated by the analysis of the singularity of the Bergman kernel of a strictly pseudoconvex domain $D \subset \mathbb{C}^{n+1}$, Fefferman [F12] launched the program of determining all local invariants of strictly pseudoconvex CR structure. This was subsequently extended to conformal geometry and to more general parabolic geometries (see, e.g., [FCL]).

A scalar local conformal invariant of weight $w$ is a scalar local Riemannian invariant $I_g(x)$ such that

$$I_{c^{w}f}(x) = e^{-w f(x)}I_g(x) \quad \forall f \in C^\infty(M, \mathbb{R}).$$

The most important conformally invariant tensor is the Weyl curvature,

$$W_{ijkl} = R_{ijkl} - (P_{jk}g_{il} + P_{il}g_{jk} - P_{jl}g_{ik} - P_{ik}g_{jl}),$$

where $P_{jk} = \frac{1}{n-2}(\rho_{jk} - \frac{n-2}{2(n-1)}g_{jk})$ denotes the Schouten tensor. The Weyl tensor is conformally invariant of weight 1, so we get scalar conformal invariants by taking

$$I_{c^{w}f}(x) = e^{-w f(x)}I_g(x) \quad \forall f \in C^\infty(M, \mathbb{R}).$$
complete tensorial contractions. For instance as invariant of weight 2 we get

\[(4.3) \quad |W|^2 = W^{ijkl} W_{ijkl},\]

and as invariants of weight 3 we have

\[(4.4) \quad W^{ijkl} W_{ijkl} \quad \text{and} \quad W^{ijkl} W_{ijkl} \quad \text{and} \quad W^{ijkl} W_{ijkl}.\]

The aim of the program of Fefferman in conformal geometry is to exhibit a basis of local conformal invariants. It was initially conjectured that such a basis should involve the Weyl conformal invariants defined in terms of the Lorentz ambient metric of Fefferman-Graham ([FG1], [FG2]) as follows.

Let \( G \) be the \( \mathbb{R}_+ \)-bundle of metrics defined by the conformal class of \( g \). We identify \( G \) with the hypersurface \( G_0 = G \times \{0\} \) in \( \tilde{G} = G \times (-1,1) \). The ambient metric then is a Ricci-flat Lorentzian metric \( \tilde{g} \) on \( \tilde{G} \) defined formally near \( G_0 \).

In odd dimension the jets of the ambient metric are defined at any order near \( G_0 \), but in even dimension there is an obstruction for defining them at order \( \geq n^2 \). In any case, the local Riemannian invariants of \( \tilde{g} \) on \( \tilde{G} \) push down to conformal invariants of \( g \) on \( M \). The latter are the Weyl conformal invariants.

For instance the Weyl curvature corresponds to the ambient curvature tensor \( \tilde{R} \).

Moreover, the Ricci flatness of \( \tilde{g} \) and the Bianchi identities imply that complete tensorial contractions covariant derivatives of \( \tilde{R} \) involving internal traces must vanish. For instance, there is no scalar Weyl conformal invariant of weight 1 (in fact there is no scalar conformal invariant of weight 1 at all) and the only non-zero scalar Weyl conformal invariant of weight 2 is \( |W|^2 \), which arises from the ambient invariant \( |\tilde{R}|^2 \) (all the other invariants (3.1) associated to the ambient metric are zero).

In addition, the scalar Weyl conformal invariants of weight 3 consist of the invariants \((4.4)\) together with the invariant \( \Phi_g \) exhibited by Fefferman-Graham ([FG1], [FG2]). The latter is the conformal invariant arising from the ambient invariant \( |\nabla \tilde{R}|^2 \) and is explicitly given by the formulas:

\[(4.5) \quad \Phi_g = |V|^2 + 16(W, U) + 16|C|^2,\]

where \( C_{ijkl} = \nabla_i A_{jk} - \nabla_k A_{ij} \) is the Cotton tensor and \( V \) and \( U \) are the tensors

\[(4.6) \quad V_{sijkl} = \nabla_s W_{ijkl} - g_{is} C_{jkl} + g_{js} C_{ikl} - g_{ks} C_{ijl} + g_{ls} C_{ikj},\]

\[(4.7) \quad U_{sijkl} = \nabla_s C_{jkl} + g^{pq} A_{sp} W_{qijkl}.\]

Next, a very important result is:

**Proposition 4.1** ([BEG Thm. 11.1]). 1) In odd dimension every scalar local conformal invariant is a linear combination of Weyl conformal invariants.

2) In even dimension every scalar local conformal invariant for weight \( w \leq \frac{n}{2} - 1 \) is a linear combination of Weyl conformal invariants.

In even dimension a description of the scalar local conformal invariants of weight \( w \geq \frac{n}{2} + 1 \) was recently presented by Graham-Hirachi [GH]. More precisely, they modified the construction of the ambient metric in such way to obtain a metric on the ambient space \( \tilde{G} \) which is smooth at any order near \( G_0 \). There is an ambiguity on the choice of a smooth ambient metric, but such a metric agrees with the ambient metric of Fefferman-Graham up to order \( < \frac{n}{2} \) near \( G_0 \).

Using a smooth ambient metric we can construct Weyl conformal invariants in the same way as we do by using the ambient metric of Fefferman-Graham.
such an invariant does not depend on the choice of the smooth ambient metric we then say that it is a ambiguity-independent Weyl conformal invariant. Not every conformal invariant arises this way, since in dimension $n = 4m$ this construction does not encapsulate the exceptional local conformal invariants of \cite{BG}. However, we have:

**Proposition 4.2 (\cite{GH}).** Let $w$ be an integer $\geq \frac{n}{2}$.

1) If $n \equiv 2 \mod 4$, and if $n \equiv 0 \mod 4$ and $w$ is odd, then every scalar local conformal of weight $w$ is a linear combination of ambiguity-independent Weyl conformal invariants.

2) If $n \equiv 0 \mod 4$ and $w$ is odd, then every scalar local conformal of weight $w$ is a linear combination of ambiguity-independent Weyl conformal invariants and of exceptional conformal invariants.

4.2. Logarithmic singularities of conformally invariant Riemannian $\Psi$DOs.

Let us now look at the logarithmic singularities of conformally invariant Riemannian $\Psi$DOs. The latter are defined as follows.

**Definition 4.3.** A conformally invariant Riemannian $\Psi$DO of order $m$ and biweight $(w, w')$ is a Riemannian invariant $m$'th order $\Psi$DO $P_g$ such that, for any $f \in C^\infty(M, \mathbb{R})$, we have

$$P_{e^f} g = e^{w'f} P_g e^{-w'f} \mod \Psi^{-\infty}(M).$$

**Remark 4.4.** It follows from (4.8) that a conformally invariant Riemannian $\Psi$DO of biweight $(w, w')$ is a Riemannian invariant $\Psi$DO of weight $w' - w$.

The main result of this section is:

**Theorem 4.5.** Let $P_g$ be a conformally invariant Riemannian $\Psi$DO of integer order $m$ and biweight $(w, w')$. Then in odd dimension, as well as in even dimension when $w' > w$, the logarithmic singularity $c_{P_g}(x)$ is of the form

$$(4.9) \quad c_{P_g}(x) = \mathcal{I}_{P_g}(x)|v_g(x)|,$$

where $\mathcal{I}_{P_g}(x)$ is a universal linear combination of Weyl conformal invariants of weight $\frac{n}{2} + w - w'$. If $n$ is even and we have $w' \leq w$, then $c_{P_g}(x)$ is of a similar form, but in this case $\mathcal{I}_{P_g}(x)$ is a local conformal invariant of weight $\frac{n}{2} + w - w'$ of the type described in Proposition 4.2.

2) Suppose that $P_g$ is elliptic and is admissible in the sense of Definition 3.1. Then in odd dimension, as well as in even dimension when $w' < w$, the Green kernel logarithmic singularity of $P$ takes the form

$$(4.10) \quad \gamma_{P_g}(x) = \mathcal{J}_{P_g}(x)|v_g(x)|,$$

where $\mathcal{J}_{P_g}(x)$ is a universal linear combination of Weyl conformal invariants of weight $\frac{n}{2} - w + w'$. If $n$ is even and we have $w' \geq w$, then $\gamma_{P_g}(x)$ is of a similar form, but in this case $\mathcal{J}_{P_g}(x)$ is a local conformal invariant of weight $\frac{n}{2} - w + w'$ of the form described in Proposition 4.2.

**Proof.** First, since $P_g$ is a Riemannian invariant $\Psi$DO of weight $w - w'$ we see from Proposition 4.5 that $c_{P_g}(x)$ is of the form $c_{P_g}(x) = \mathcal{I}_{P_g}(x)|v_g(x)|$, where $\mathcal{I}_{P_g}(x)$ is a local Riemannian invariant of weight $w - w'$. 
Let \( f \in C^\infty(M, \mathbb{R}) \). As \( P_g \) is conformally invariant of biweight \( (w, w') \), it follows from Proposition 2.1 that \( c_{P_g}(f) = e^{-(w-w')f}c_{P_g}(x) \). Since \( |v_{\gamma}(x)| = e^{\frac{x}{2}f(x)}|v_{\gamma}(x)| \) we see that \( \mathcal{I}_{P_g}(x) = e^{-(\frac{x}{2}+w'w)f(x)}\mathcal{I}_{P_g}(x) \). Thus \( \mathcal{I}_{P_g}(x) \) is a local conformal invariant of weight \( \frac{x}{2} + w - w' \). It then follows from Proposition 4.1 that in odd dimension, and in even dimension when \( w < w' \), the invariant \( \mathcal{I}_{P_g}(x) \) is a linear combination of Weyl conformal invariants of weight \( \frac{x}{2} + w - w' \). When \( n \) is even and we have \( w' \leq w \) the invariant \( \mathcal{I}_{P_g}(x) \) is of the form described in Proposition 4.2.

Suppose now that \( P_g \) is elliptic and is admissible. In the same way as above, it follows from Proposition 2.1 and Proposition 3.3 that \( \gamma_{P_g}(x) \) takes the form \( \gamma_{P_g}(x) = \mathcal{I}_{P_g}(x)|v_{\gamma}(x)| \), where \( \mathcal{I}_{P_g}(x) \) is a local conformal invariant of weight \( \frac{x}{2} - \frac{n}{2} - w + w' \). We then can apply Proposition 4.1 to deduce that in odd dimension, as well as in even dimension when \( w \geq w' \), the invariant \( \mathcal{J}_{P_g}(x) \) is a linear combination of Weyl conformal invariants of weight \( \frac{x}{2} - \frac{n}{2} + w + w' \). When \( n \) is even and we have \( w' \geq w \) the invariant \( \mathcal{J}_{P_g}(x) \) is of the form described in Proposition 4.2. □

We shall now make use of Theorem 4.5 to get a precise geometric description of the Green kernel logarithmic singularities of the GJMS operators \( \Box_g^{(k)} \).

**Theorem 4.6.** 1) In odd dimension the Green kernel logarithmic singularity \( \gamma_{\Box_g^{(k)}}(x) \) is always zero.

2) In even dimension and for \( k = 1, \ldots, \frac{n}{2} \) we have

\[
\gamma_{\Box_g^{(k)}}(x) = c_g^{(k)}(x)dv_g(x),
\]

where \( c_g^{(k)}(x) \) is a linear combination of Weyl conformal invariants of weight \( \frac{x}{2} - k \). In particular, we have

\[
c_g^{(\frac{x}{2})}(x) = (4\pi)^{-\frac{n}{2}}\frac{n}{(n/2)!}, \quad c_g^{(\frac{x}{2} - 1)}(x) = 0, \quad c_g^{(\frac{x}{2} - 2)}(x) = \alpha_n|W(x)|^2_g,
\]

\[
c_g^{(\frac{x}{2} - 3)}(x) = \beta_n W_{ij}^k W_{kq}^p W_{pq}^i j + \gamma_n W_i^j W_i^k W_k^l q^j + \delta_n \Phi_g,
\]

where \( W \) is the Weyl curvature tensor, \( \Phi_g \) is the Fefferman-Graham invariant (4.3) and \( \alpha_n, \beta_n, \gamma_n \) and \( \delta_n \) are universal constants depending only on \( n \).

**Proof.** Let \( Q_g^{(k)} \in \mathcal{P}^{-2k}(M) \) be a parametrix for \( \Box_g^{(k)} \). Since \( \Box_g^{(k)} \) is a differential operator, using (3.1) - (3.5) one can check that if \( q^{(k)} \sim \sum q^{(k)}_{-2k-j} \) denotes the symbol of \( Q_g^{(k)} \) in local coordinates then we have \( q^{(k)}_{-2k-j}(x, -\xi) = (-1)^{-2k-j}q^{(k)}_{-2k-j}(x, \xi) \) for all \( j \geq 0 \). Combining this with (4.3) then gives

\[
c_{Q_g^{(k)}}(x) = (2\pi)^{-n} \int_{S^{n-1}} q^{(k)}_{-n}(x, -\xi)d^{n-1}\xi = (-1)^n c_{Q_g^{(k)}}(x).
\]

Hence \( c_{Q_g^{(k)}}(x) \) must vanish when \( n \) is odd. Since by definition \( \gamma_{\Box_g^{(k)}}(x) = c_{Q_g^{(k)}}(x) \) this shows that \( \gamma_{\Box_g^{(k)}}(x) \) is always zero in odd dimension.

Next, suppose that \( n \) is even and \( k \) is between 1 and \( \frac{n}{2} \). It follows from the construction in GJMS that \( \Box_g^{(k)} \) is a Riemannian invariant operator, so by combining this with (2.3) we see that \( \Box_g^{(k)} \) is a conformally invariant Riemannian operator of biweight \( (\frac{x}{2} - \frac{n}{2} - k) \). Furthermore, by (2.4) the principal symbol of \( \Box_g^{(k)} \) agrees with that of \( \Delta_g^{(k)} \), so \( \Box_g^{(k)} \) is admissible in the sense of Definition 3.1. We then can
apply Theorem 4.3 to deduce that \( \gamma_{\Box_g}^{(k)}(x) \) is of the form \( \gamma_{\Box_g}^{(k)}(x) = c_g^{(k)}(x) |v_g(x)| \), where \( c_g^{(k)}(x) \) is a linear combination of Weyl conformal invariants of weight \( \frac{n}{2} - k \) of \( \Box_g \).

As mentioned earlier there are no scalar Weyl conformal invariants of weight 1, the only invariant of weight 2 is \( |W|^2 \), and the only Weyl invariants of weight 3 are \( W_{ij} k l W_{lk} \rho q W_{pq} ij \) and \( W_{i} j k W_{i} \rho l W_{pq} \rho q \) and the invariant \( \Phi_g \). From this we get the formulas (4.12) and (4.13) for \( c_g^{(k)}(x) \) when \( k = 1, 2, 3 \).

The formula for \( c_\gamma^{(n)}(x) \) follows from a direct computation. More precisely, as \( Q_\gamma^{(2)} \) has order \(-n\) its symbol of degree \(-n\) agrees with its principal symbol, which is the inverse of that of \( \Box_g^{(2)} \). By (2.4) the latter agrees with the principal symbol of \( \Delta_\gamma^{(2)} \). Therefore, in local coordinates the principal symbol of \( \Box_g^{(2)} \) is \( p_n(\frac{\gamma}{\Box_g})(x, \xi) = |\xi|^{2n} \), where \( |\xi|^2 := g^{ij}(x)\xi_i \xi_j \), and that of \( Q_\gamma^{(2)} \) is \( q_n^{(2)}(x, \xi) = |\xi|^{-n} \).

As \( c_g^{(2)} \right \sqrt{g(x)} dx = \gamma_{\Box_g}^{(2)}(x) = c_g^{(2)}(x) \right (4.13 \right ) \) using (1.5) we see that \( c_g^{(2)}(x) \right \) is equal to \( (2\pi)^{n-1} \int_{S^{n-1}} |\xi|^{-n} d^{n-1} \xi = (2\pi)^{-n} \int_{S^{n-1}} |\xi|^{-n} d^{n-1} \xi = (2\pi)^{-n} |S^{n-1}|. \)

Since \( |S^{n-1}| = \frac{2\pi^{\frac{n}{2}}}{\Gamma(n/2)} = \frac{n\pi^{\frac{n}{2}}}{(n/2)!} \) it follows that \( c_g^{(2)}(x) = \frac{n(4\pi)^{\frac{n}{2}}}{(n/2)!} \) as desired.

Finally, we can get an explicit expression for \( c_g^{(1)}(x) \) in dimension 6 and 8 by making use the explicit computations by Parker-Rosenberg [PR] in these dimensions of the coefficient \( a_{n-2}(\Box_g)(x) \right \) of \( t^{-1} \) in the heat kernel asymptotics (1.11) for the Yamabe operator.

Assume first that \( M \) compact. Then by (1.13) we have \( 2\gamma_{\Box_g}(x) = a_{n-2}(\Box_g)(x) \), so by using [PR] Prop. 4.2 we see that in dimension 6 we have

\[
(4.16) \quad c_g^{(1)}(x) = \frac{1}{360} |W(x)|^2,
\]

while in dimension 8 we get

\[
(4.17) \quad c_g^{(1)}(x) = \frac{1}{90720} (81\Phi_g + 352 W_{ij} k l W_{lk} \rho q W_{pq} ij + 64 W_{i} j k W_{i} \rho l W_{pq} \rho q W_{pq} \rho q).
\]

In fact, as \( c_g^{(1)}(x) \) is a local Riemannian invariant its expression in local coordinates is independent of whether \( M \) is compact or not. Therefore, the above formulas continue to hold when \( M \) is not compact.

5. Heisenberg calculus and noncommutative residue

The relevant pseudodifferential calculus to study the main geometric operators on a CR manifold is the Heisenberg calculus of Beals-Greiner [BG] and Taylor [Tay]. In this section we recall the main definitions and properties of this calculus.

5.1. Heisenberg manifolds. The Heisenberg calculus holds in full generality on Heisenberg manifolds. Such a manifold consists of a pair \((M, H)\) where \( M \) is a manifold and \( H \) is a distinguished hyperplane bundle of \( TM \). This definition covers many examples: Heisenberg group, CR manifolds, contact manifolds, as well as (codimension 1) foliations. In addition, given another Heisenberg manifold \((M', H')\) we say that a diffeomorphism \( \phi : M \rightarrow M' \) is a Heisenberg diffeomorphism when \( \phi_* H = H' \).
The terminology Heisenberg manifold stems from the fact that the relevant tangent structure in this setting is that of a bundle \( GM \) of graded nilpotent Lie groups (see, e.g., [BG], [EMM], [Gro], [Po1], [Ro]). This tangent Lie group bundle can be described as follows.

First, there is an intrinsic Levi form as the 2-form \( \mathcal{L} : H \times H \to TM/H \) such that, for any point \( a \in M \) and any sections \( X \) and \( Y \) of \( H \) near \( a \), we have

\[
\mathcal{L}_a(X(a),Y(a)) = [X,Y](a) \quad \text{mod} \ H_a.
\]

In other words the class of \( [X,Y](a) \) modulo \( H_a \) depends only on \( X(a) \) and \( Y(a) \), not on the germs of \( X \) and \( Y \) near \( a \) (see [Po1]).

We define the tangent Lie algebra bundle \( \mathfrak{g}M \) as the graded Lie algebra bundle consisting of \( (TM/H) \oplus H \) together with the fields of Lie bracket and dilations such that, for sections \( X_0, Y_0 \) of \( TM/H \) and \( X', Y' \) of \( H \) and for \( t \in \mathbb{R} \), we have

\[
\begin{align*}
[X_0 + X', Y_0 + Y'] &= \mathcal{L}(X', Y'), \quad t.(X_0 + X') = t^2X_0 + tX'.
\end{align*}
\]

Each fiber \( \mathfrak{g}_aM \) is a two-step nilpotent Lie algebra so, by requiring the exponential map to be the identity, the associated tangent Lie group bundle \( GM \) appears as \( (TM/H) \oplus H \) together with the grading above and the product law such that, for sections \( X_0, Y_0 \) of \( TM/H \) and \( X', Y' \) of \( H \), we have

\[
(X_0 + X').(Y_0 + Y') = X_0 + Y_0 + \frac{1}{2}\mathcal{L}(X',Y') + X' + Y'.
\]

Moreover, if \( \phi \) is a Heisenberg diffeomorphism from \( (M, H) \) onto a Heisenberg manifold \( (M', H') \) then, as we have \( \phi_*H = H' \), we get linear isomorphisms from \( TM/H \) onto \( TM'/H' \) and from \( H \) onto \( H' \), which can be combined together to give rise to a linear isomorphism \( \phi^*_{H} : (TM/H) \oplus H \to (TM'/H') \oplus H' \). In fact \( \phi^*_{H} \) is a graded Lie group isomorphism from \( GM \) onto \( GM' \) (see [Po1]).

### 5.2. Heisenberg calculus

The initial idea in the Heisenberg calculus, which goes back to Stein, is to construct a class of operators on a Heisenberg manifold \( (M^{d+1}, H) \), called \( \Psi_H \) DOs, which at any point \( a \in M \) are modeled on homogeneous left-invariant convolution operators on the tangent group \( G_aM \).

Locally the \( \Psi_H \) DOs can be described as follows. Let \( U \subset \mathbb{R}^{d+1} \) be an open of local coordinates together with a frame \( X_0, \ldots, X_d \) of \( TU \) such that \( X_1, \ldots, X_d \) span \( H \). Such a frame is called a \( H \)-frame. Moreover, on \( \mathbb{R}^{d+1} \) we introduce the dilations and the pseudonorm,

\[
\begin{align*}
t.\xi &= (t^2 \xi_0, t\xi_1, \ldots, t\xi_d), \quad t > 0, \\
\|\xi\| &= (\xi_0^2 + \xi_1^4 + \ldots + \xi_d^4)^{1/4}.
\end{align*}
\]

In addition, for any multi-order \( \alpha \in \mathbb{N}^{d+1} \) we set \( \langle \beta \rangle = 2\beta_0 + \beta_1 + \ldots + \beta_d \).

The Heisenberg symbols are defined as follows.

**Definition 5.1.** 1) \( S_m(U \times \mathbb{R}^{d+1}), \ m \in \mathbb{C}, \) is the space of functions \( p(x,\xi) \) in \( C^\infty(U \times \mathbb{R}^{d+1} \setminus \{0\}) \) such that \( p(x, t\xi) = t^m p(x, \xi) \) for any \( t > 0 \).

2) \( S^m(U \times \mathbb{R}^{d+1}), \ m \in \mathbb{C}, \) consists of functions \( p \in C^\infty(U \times \mathbb{R}^{d+1}) \) with an asymptotic expansion \( p \sim \sum_{j \geq 0} p_{m-j}, \ p_k \in S_k(U \times \mathbb{R}^{d+1}), \) in the sense that, for any integer \( N \), any compact \( K \subset U \) and any multi-orders \( \alpha, \beta \), there exists a
constant $C_{NK\alpha\beta} > 0$ such that, for any $x \in K$ and any $\xi \in \mathbb{R}^{d+1}$ so that $\|\xi\| \geq 1$, we have
\begin{equation}
|\partial_x^\alpha \partial_\xi^\beta (p - \sum_{j<N} p_{m-j})(x, \xi)| \leq C_{NK\alpha\beta} \|\xi\|^{\|R_{m-\delta}-N\|}.
\end{equation}

Next, for $j = 0, \ldots, d$ let $\sigma_j(x, \xi)$ denote the symbol (in the classical sense) of the vector field $\frac{1}{i} X_j$ and set $\sigma = (\sigma_0, \ldots, \sigma_d)$. Then for $p \in S^m(U \times \mathbb{R}^{d+1})$ we let $p(x, -iX)$ be the continuous linear operator from $C^\infty_c(U)$ to $C^\infty(U)$ such that
\begin{equation}
p(x, -iX)u(x) = (2\pi)^{-(d+1)} \int e^{ix \cdot \xi} p(x, \sigma(x, \xi)) \hat{u}(\xi) d\xi \quad \forall u \in C^\infty_c(U).
\end{equation}

Let $(M^{d+1}, H)$ be a Heisenberg manifold and let $\mathcal{E}$ be a vector bundle over $M$. We define $\Psi_H DOs$ on $M$ acting on the sections of $\mathcal{E}$ as follows.

**Definition 5.2.** $\Psi^m_H(M, \mathcal{E})$, $m \in \mathbb{C}$, consists of continuous operators $P$ from $C^\infty_c(M, \mathcal{E})$ to $C^\infty(M, \mathcal{E})$ such that:

(i) The Schwartz kernel of $P$ is smooth off the diagonal;

(ii) In any trivializing local coordinates equipped with a $H$-frame $X_0, \ldots, X_d$ the operator $P$ can be written as
\begin{equation}
P = p(x, -iX) + R,
\end{equation}
where $p(x, \xi)$ is a Heisenberg symbol of order $m$ and $R$ is a smoothing operator.

Let $\mathfrak{g}^* M$ denote the (linear) dual of the Lie algebra bundle $\mathfrak{g} M$ of $GM$ with canonical projection $pr : \mathfrak{g}^* M \rightarrow M$. As shown in [Po2] (see also [EM]) the principal symbol of $P \in \Psi^m_H(M, \mathcal{E})$ can be intrinsically defined as a symbol $\sigma_m(P)$ of the class below.

**Definition 5.3.** $S_m(\mathfrak{g}^* M, \mathcal{E})$, $m \in \mathbb{C}$, consists of sections $p \in C^\infty(\mathfrak{g}^* M \setminus 0, \text{End} pr^* \mathcal{E})$ which are homogeneous of degree $m$ with respect to the dilations in (5.3), i.e., we have $p(x, \lambda \xi) = \lambda^m p(x, \xi)$ for any $\lambda > 0$.

For any $a \in M$ the convolution on $G_a M$ gives rise under the (linear) Fourier transform to a bilinear product for homogeneous symbols,
\begin{equation}
*^a : S_{m_1}(\mathfrak{g}^* M, \mathcal{E}_a) \times S_{m_2}(\mathfrak{g}^* M, \mathcal{E}_a) \rightarrow S_{m_1+m_2}(\mathfrak{g}^* M, \mathcal{E}_a),
\end{equation}
This product depends smoothly on $a$ as much so it gives rise to the product,
\begin{equation}
* : S_{m_1}(\mathfrak{g}^* M, \mathcal{E}) \times S_{m_2}(\mathfrak{g}^* M, \mathcal{E}) \rightarrow S_{m_1+m_2}(\mathfrak{g}^* M, \mathcal{E}),
\end{equation}
\begin{equation}
p_{m_1} * p_{m_2}(a, \xi) = [p_{m_1}(a, \cdot) *^a p_{m_2}(a, \cdot)](\xi).
\end{equation}
This provides us with the right composition for principal symbols, since for any operators $P_1 \in \Psi^m_H(M, \mathcal{E})$ and $P_2 \in \Psi^{m_2}_H(M, \mathcal{E})$ such that $P_1$ or $P_2$ is properly supported we have
\begin{equation}
\sigma_{m_1+m_2}(P_1 P_2) = \sigma_{m_1}(P_1) * \sigma_{m_2}(P_2).
\end{equation}

Notice that when $G_a M$ is not commutative, i.e., when $\mathcal{E}_a \neq 0$, the product $*^a$ is not anymore the pointwise product of symbols and, in particular, it is not commutative. As a consequence, unless when $H$ is integrable, the product for Heisenberg symbols, while local, is not microlocal (see [BGr]).

When the principal symbol of $P \in \Psi^m_H(M, \mathcal{E})$ is invertible with respect to the product $*$, the symbolic calculus of [BGr] allows us to construct a parametrix for
$P$ in $\Psi_H^{-m}(M, \mathcal{E})$. In particular, although not elliptic, $P$ is hypoelliptic with a controlled loss/gain of derivatives (see [BGr]).

In general, it may be difficult to determine whether the principal symbol of a given operator $P \in \Psi_H^{-m}(M, \mathcal{E})$ is invertible with respect to the product $\ast$, but this can be completely determined in terms of a representation theoretic criterion on each tangent group $G_a M$, the so-called Rockland condition (see [Po2], Thm. 3.3.19). In particular, if $\sigma_m(P)(a,.)$ is pointwise invertible with respect to the product $\ast^a$ for any $a \in M$ then $\sigma_m(P)$ is globally invertible with respect to $\ast$.

5.3. Logarithmic singularity and noncommutative residue. It is possible to characterize the $\Psi_H$DOs in terms of their Schwartz kernels (see [BGr]). As a consequence we get the following description of the singularity near the diagonal of the Schwartz kernel of a $\Psi_H$DO.

In the sequel, given an open of local coordinates $U \subset \mathbb{R}^{d+1}$ equipped with a $H$-frame $X_0, \ldots, X_d$ of $TU$, for any $a \in U$ we let $\psi_a$ denote the unique affine change of variables such that $\psi_a(a) = 0$ and $(\psi_a, X_j)(0) = \frac{\partial}{\partial x_j}$ for $j = 0, 1, \ldots, d + 1$.

Definition 5.4. The local coordinates provided by $\psi_a$ are called privileged coordinates centered at $a$.

Throughout the rest of the paper the notion of homogeneity refers to homogeneity with respect to the anisotropic dilations (5.4).

Proposition 5.5 ([Po3] Prop. 3.11]). Let $\Psi_H^m(M, \mathcal{E})$, $m \in \mathbb{Z}$.

1) In local coordinates equipped with a $H$-frame the kernel $k_P(x,y)$ has a behavior near the diagonal $y = x$ of the form

$$k_P(x,y) = \sum_{-(m+d+2) \leq j \leq -1} a_j(x,-\psi_x(y)) - c_P(x) \log \|\psi_x(y)\| + O(1),$$

where $a_j(x,y) \in C^\infty(U \times (\mathbb{R}^n \setminus 0))$ is homogeneous of degree $j$ in $y$, and we have

$$c_P(x) = (2\pi)^{-(d+1)} \int_{\|\xi\|=1} p_{-(d+2)}(x,\xi) \nu_E d\xi,$$

where $p_{-(d+2)}(x,\xi)$ is the symbol of degree $-(d+2)$ of $P$ and $E$ denotes the anisotropic radial vector $2x^0 \partial_x^0 + x^1 \partial_x^1 + \ldots + x^d \partial_x^d$.

2) The coefficient $c_P(x)$ makes sense globally on $M$ as an END $\mathcal{E}$-valued density.

Let $P \in \Psi_H^{-m}(M, \mathcal{E})$ be such that its principal symbol is invertible in the Heisenberg calculus sense and let $Q \in \Psi_H^{-m}(M, \mathcal{E})$ be a parametrix for $P$. Then $Q$ is uniquely defined modulo smoothing operators, so the logarithmic singularity $c_Q(x)$ does not depend on the particular choice of $Q$.

Definition 5.6. If $P \in \Psi_H^{-m}(M, \mathcal{E})$, $m \in \mathbb{Z}$, has an invertible principal symbol, then its Green kernel logarithmic singularity is the density

$$\gamma_P(x) := c_Q(x),$$

where $Q \in \Psi_H^{-m}(M, \mathcal{E})$ is any given parametrix for $P$.

In the same way as for classical PDOs the logarithmic singularity densities are related to the construction of the noncommutative residue trace for the Heisenberg calculus (see [Po3]).
Let \( \Psi^\int_H(M, \mathcal{E}) = \cup_{m < -(d+2)} \Psi^m(M, \mathcal{E}) \) be the class of \( \Psi_H \)DOs whose symbols are integrable with respect to the \( \xi \)-variable. If \( P \) is an operator in this class, then the restriction of its Schwartz kernel \( k_P(x, y) \) to the diagonal defines a smooth \( \text{End} \mathcal{E} \)-valued density \( k_P(x, x) \). In particular, if \( M \) is compact, then \( P \) is trace-class and its trace is given by (1.7).

The map \( P \to k_P(x, x) \) admits an analytic continuation \( P \to t_P(x) \) to the class \( \Psi^\infty_H(M, \mathcal{E}) \) of non-integer order \( \Psi_H \)DOs, where is analyticity is meant with respect to holomorphic families of \( \Psi_H \)DOs as defined in [Po2]. Moreover, if \( P \in \Psi^\infty_H(M, \mathcal{E}) \) and if \( (P(z))_{z \in \mathbb{C}} \) is a holomorphic family of \( \Psi_H \)DOs such that \( \text{ord}P(z) = \text{ord}P + z \) and \( P(0) = P \), then the map \( z \to t_P(z)(x) \) has at worst a simple pole singularity at \( z = 0 \) in such way that

\[
\text{Res}_{z=0} t_P(z)(x) = -c_P(x).
\]

Assume now that \( M \) is compact. Then the noncommutative residue for the Heisenberg calculus is the linear functional \( \text{Res} \) on \( \Psi^\infty_H(M, \mathcal{E}) \) defined by

\[
\text{Res} P := \int_M \text{tr}_\mathcal{E} c_P(x) \quad \forall P \in \Psi^\infty_H(M, \mathcal{E}).
\]

It follows from (5.16) that if \( (P(z))_{z \in \mathbb{C}} \) is a holomorphic family of \( \Psi_H \)DOs such that \( \text{ord}P(z) = \text{ord}P + z \) and \( P(0) = P \), then the map \( z \to \text{Trace}(P(z)) \) has an analytic extension to \( \mathbb{C} \setminus \mathbb{Z} \) with at worst a simple at \( z = 0 \) in such way that

\[
\text{Res}_{z=0} \text{Trace}(P(z)) = - \text{Res} P.
\]

Using this it is not difficult to check that the above noncommutative residue is a trace on \( \Psi^\infty_H(M, \mathcal{E}) \). This is even the unique trace up to constant multiple when \( M \) is connected (see [Po3]).

Finally, suppose that \( M \) is endowed with a positive density and \( \mathcal{E} \) is endowed with a Hermitian metric. Let \( P : C^\infty(M, \mathcal{E}) \to C^\infty(M, \mathcal{E}) \) be a selfadjoint \( \Psi_H \)DO of integer order \( m \geq 1 \) such that the union set \( \theta(P) \) of the principal cuts of its principal symbol agrees with \( \mathbb{C} \setminus [0, \infty) \) (see [Po5] for the precise definition of a principal cut). This implies that the principal symbol of \( P \) is invertible in the Heisenberg calculus sense. This also implies that \( P \) is bounded from below, hence gives rise to a heat semigroup \( e^{-tP} \), \( t \geq 0 \).

For any \( t > 0 \) the operator \( e^{-tP} \) has a smooth Schwartz kernel \( k_t(x, y) \) in \( C^\infty(M, \mathcal{E}) \otimes C^\infty(M, \mathcal{E}^* \otimes |\Lambda|(M)) \), and as \( t \to 0^+ \) we have the heat kernel asymptotics,

\[
k_t(x, x) \sim t^{-\frac{d+2}{m}} \sum_{j \geq 0} t^{j \sigma_j} a_j(P)(x) + \log t \sum_{k \geq 0} t^{k \sigma_k} b_k(P)(x),
\]

where the asymptotics takes place in \( C^\infty(M, \text{End} \mathcal{E} \otimes |\Lambda|(M)) \), and when \( P \) is a differential operator we have \( a_{2j-1}(P)(x) = b_j(P)(x) = 0 \) for all \( j \in \mathbb{N} \) (see [BGS], [Po2], [Po5]).

As in (1.12) if for \( j = 0, \ldots, n - 1 \) we set \( \sigma_j = \frac{d+2-2j}{m} \), then we have

\[
m \gamma_{P^{-\sigma_j}}(x) = \text{Res}_{s=\gamma_j} t_{P^{-\sigma_j}}(x) = \Gamma(\sigma_j)^{-1} a_{2j}(P)(x).
\]

In particular, we get

\[
m \gamma_{P}(x) = a_{d+2-m}(P)(x).
\]
6. Logarithmic singularities of contact invariant operators

The aim of this section is to prove an analogue of Proposition 2.1 in the setting of contact geometry.

Let \((M^{2n+1}, H)\) be an orientable contact manifold. This means that \((M, H)\) is an orientable Heisenberg manifold such that \(H\) can be represented as the annihilator of a globally defined contact form, that is, a 1-form \(\theta\) on \(M\) such that \(H = \ker \theta\) and \(d\theta|_H\) is non-degenerate. We further assume that \(\theta\) is chosen in such a way that the top-degree form \(d\theta^n \wedge \theta\) is in the orientation class of \(M\). This uniquely determines the contact form \(\theta\) up to a conformal factor.

As we will recall in Section 8, the CR GJMS of Gover-Graham \([GG]\) on a pseudo-hermitian manifold transform covariantly under a conformal change of contact form. These operators include the CR Yamabe operator of Jerison-Lee \([JL1]\), for which N.K. Stanton \([St\), p. 276] determined the behavior of the logarithmic singularity of the Green kernel under a conformal change of contact form.

More generally, let \(\Theta\) be the class of contact forms on \(M\) that are conformal multiples of \(\theta\), and let \((P_\theta)_{\theta \in \Theta} \subset \Psi^m_H(M, \mathcal{E})\) be a family of \(m\)th order \(\Psi_H\) DOs in such a way that there exist real numbers \(w\) and \(w'\) so that, for any \(f \in C^\infty(M, \mathbb{R})\), we have

\[
P_{e^{f\theta}} = e^{w'f}P_\theta e^{-wf} \quad \text{mod} \; \Psi^{-\infty}_H(M, \mathcal{E}).
\]

Then the following holds.

**Proposition 6.1.** 1) We have

\[
c_{P_{e^{f\theta}}}(x) = e^{-(w-w')f(x)}c_{P_\theta}(x) \quad \forall f \in C^\infty(M, \mathbb{R}).
\]

2) Suppose that the principal symbol of \(P_\theta\) is invertible in the sense of the Heisenberg calculus. Then we have

\[
\gamma_{P_{e^{f\theta}}}(x) = e^{-(w'-w)f(x)}\gamma_{P_\theta}(x) \quad \forall f \in C^\infty(M, \mathbb{R}).
\]

3) Suppose that, for any \(\bar{\theta} \in \Theta\), the operator is \(P_{\bar{\theta}}\) is selfadjoint with respect to some density on \(M\) and some Hermitian metric on \(\mathcal{E}\), and the union-set of the principal cuts of the principal symbol of \(P_{\bar{\theta}}\) is \(\mathbb{C} \setminus [0, \infty)\). Then we have

\[
a_{2n+2-m}(P_{e^{f\theta}})(x) = e^{-(w'-w)f(x)} a_{2n+2-m}(P_\theta)(x) \quad \forall f \in C^\infty(M, \mathbb{R}),
\]

where \(a_{2n+2-m}(P_{\bar{\theta}})(x)\) is the coefficient of \(t^{-1}\) in the heat kernel asymptotics \([5.19]\) for \(P_{\bar{\theta}}\).

**Proof.** The proof is similar to that of Proposition 2.1. Let \(f \in C^\infty(M, \mathbb{R})\), set \(\bar{\theta} = e^{f\theta}\) and let \(k_{P_\theta}(x, y)\) and \(k_{P_{\bar{\theta}}}(x, y)\) denote the respective Schwartz kernels of \(P_\theta\) and \(P_{\bar{\theta}}\). Then it follows from (6.2) that we have

\[
k_{P_{\bar{\theta}}}(x, y) = e^{w'f(x)}k_{P_\theta}(x, y)e^{-wf(y)} + O(1).
\]

Next, let \(U \subset \mathbb{R}^{2n+1}\) be an open of local coordinates equipped with a \(H\)-frame \(X_0, \ldots, X_d\). By Proposition 5.5, the kernel \(k_{P_\theta}(x, y)\) has a behavior near the diagonal of the form

\[
k_{P_\theta}(x, y) = \sum_{-(m+2n+2) \leq j \leq -1} a_j(x, \psi(y)) - c_{P_\theta}(x) \log \|\psi_\epsilon(y)\| + O(1),
\]
where \( a_j(x, y) \in C^\infty(U \times (\mathbb{R}^n \setminus 0)) \) is homogeneous of degree \( j \) with respect to \( y \).

Combining this with (6.5) then gives

\[
(6.7) \quad k_{P_\theta}(x, y) = \sum_{-(m+2n+2) \leq \alpha + j \leq -1} \frac{1}{\alpha!} \partial_y^\alpha b(x, 0) y^\alpha a_j(x, y) + O(1),
\]

where we have set \( b(x, y) = e^{-w f(x)} \),

The Taylor expansion of \( b(x, y) \) near \( y = 0 \) can be written in the form

\[
(6.8) \quad b(x, y) = \sum_{\alpha < m} \frac{1}{\alpha!} \partial_y^\alpha b(x, 0) y^\alpha + \sum_{\alpha = m} y^\alpha r_\alpha(x, y),
\]

where the functions \( r_\alpha(x, y) \) are smooth near \( y = x \). By arguing as in the proof of Proposition 2.1 we can show that

\[
(6.9) \quad b(x, y) a_j(x, y) = \sum_{\alpha + j \leq -1} \frac{1}{\alpha!} \partial_y^\alpha b(x, 0) y^\alpha a_j(x, y) + O(1),
\]

\[
(6.10) \quad b(x, y) \log \|y\| = b(x, 0) \log \|y\| + O(1) = e^{-(w-w')f(x)} \log \|y\| + O(1).
\]

Combining this with (6.7) then shows that

\[
(6.11) \quad k_{P_\theta}(x, y) = \sum_{-(m+2n+2) \leq \alpha + j \leq -1} \frac{1}{\alpha!} \partial_y^\alpha b(x, 0) \psi_x(y)^\alpha a_j(x, y) - c_{P_\theta}(x) e^{-(w-w')f(x)} \log \|\psi_x(y)\| + O(1).
\]

This shows that \( c_{P_\theta}(x) = e^{-2(w-w')f(x)} c_{P_\theta}(x) \) as desired, so the 1st part of the proposition is proved.

Next, suppose that the principal symbol of \( P_\theta \) is invertible in the Heisenberg calculus sense. Because of (6.1) this implies that the principal symbol of \( P_\theta \) is invertible as well. Let \( Q_\theta \in \Psi^{-m}_H(M, \mathcal{E}) \) be a parametrix for \( P_\theta \) and, similarly, let \( Q_\hat{\theta} \in \Psi^{-m}_H(M, \mathcal{E}) \) be a parametrix for \( P_\hat{\theta} \). By arguing as in the proof of Proposition 2.1 we can show that

\[
(6.12) \quad Q_\hat{\theta} = e^{w f} Q_\theta e^{-w' f} \mod \Psi^{-\infty}(M, \mathcal{E}).
\]

Therefore, it follows from the first part of the proof that

\[
(6.13) \quad \gamma_{P_\theta}(x) = c_{Q_\theta}(x) = e^{-(w'-w)f(x)} c_{Q_\theta}(x) = e^{-(w'-w)f(x)} \gamma_{P_\theta}(x).
\]

The 2nd part of the proposition is thus proved.

Finally, thanks to (6.21) the third part of the proposition is an immediate consequence of the second one. \( \square \)

**Remark 6.2.** The third part of Proposition 6.1 has also been obtained by N.K. Stanton [SI] Thm. 3.3 in the special case of the CR Yamabe operator on a pseudohermitian manifold.
7. PSEUDOHERMITIAN INVARIANT $\Psi_H$ DOs AND THEIR LOGARITHMIC SINGULARITIES

In this section, after some preliminary work on local pseudohermitian invariants and pseudohermitian invariant $\Psi_H$ DOs, we shall prove that the logarithmic singularities of the Schwartz kernels and Green kernels of pseudohermitian invariant $\Psi_H$ DOs give rise local pseudohermitian invariants.

7.1. The geometric set-up. Let $(M^{2n+1}, H)$ be a compact orientable CR manifold. Thus $(M^{2n+1}, H)$ is a Heisenberg manifold and $H$ is equipped with a complex structure $J \in C^\infty(M, \text{End } H)$, $J^2 = -1$, in such way that $T_{1,0} := \ker(J + i) \subset T\mathbb{C} M$ is a complex rank $n$ subbundle integrable in Fröbenius’ sense (i.e. $C^\infty(M, T_{1,0})$ is closed under the Lie bracket of vector fields). In addition, we set $T_{0,1} := T_{1,0} = \ker(J - i)$.

Since $M$ is orientable and $H$ is orientable by means of its complex structure, there exists a global non-vanishing real 1-form $\theta$ such that $H = \ker \theta$. Associated to $\theta$ is its Levi form, i.e., the Hermitian form on $T_{1,0}$ such that

$$(7.1) \quad L_\theta(Z, W) = -i \theta(Z, \overline{W}) = i \theta([Z, W]) \quad \forall Z, W \in C^\infty(M, T_{1,0}).$$

We further assume that $M$ is strictly pseudoconvex, that is, we can choose $\theta$ so that $L_\theta$ is positive definite at every point. In particular $\theta$ is a contact form on $M$. In the terminology of [We] the datum of such a contact form defines a pseudohermitian structure on $M$.

Since $\theta$ is a contact form there exists a unique vector field $X_0$ on $M$, called the Reeb field, such that $i_{X_0} \theta = 1$ and $i_{X_0} d\theta = 0$. Let $N \subset T\mathbb{C} M$ be the complex line bundle spanned by $X_0$. We then have the splitting

$$(7.2) \quad T\mathbb{C} M = N \oplus T_{1,0} \oplus T_{0,1}.$$ 

The Levi metric $h_\theta$ is the unique Hermitian metric on $T\mathbb{C} M$ such that:

- The splitting (7.2) is orthogonal with respect to $h_\theta$;
- $h_\theta$ commutes with complex conjugation;
- We have $h(X_0, X_0) = 1$ and $h_\theta$ agrees with $L_\theta$ on $T_{1,0}$.

Notice that the volume form of $h_\theta$ is $\frac{1}{n!} d\theta^n \wedge \theta$.

As proved by Tanaka [Ta] and Webster [We] the datum of the pseudohermitian contact form $\theta$ uniquely defines a connection, the Tanaka-Webster connection, which preserves the pseudohermitian structure of $M$, i.e., such that $\nabla \theta = 0$ and $\nabla J = 0$. It can be defined as follows.

Let $\{Z_j\}$ be a frame of $T_{1,0}$. We set $Z_j = \overline{Z_j}$. Then $\{X_0, Z_j, Z_j\}$ forms a frame of $T\mathbb{C} M$. In the sequel such a frame will be called an admissible frame of $T\mathbb{C} M$. Let $\{\theta, \theta^j, \theta^k\}$ be the coframe of $T^*_\mathbb{C} M$ dual to $\{X_0, Z_j, Z_j\}$. With respect to this coframe we can write $d\theta = \iota h_{jk} \theta^j \wedge \theta^k$.

Using the matrix $(h_{jk})$ and its inverse $(h^{jk})$ to lower and raise indices, the connection 1-form $\omega = (\omega^k)$ and the torsion form $\tau_j = A_{jk} \theta^k$ of the Tanaka-Webster connection are uniquely determined by the relations

$$(7.3) \quad d\theta^k = \theta^j \wedge \omega^k_j + \theta \wedge \tau^k, \quad \omega^k_j + \omega^k_j = dh^{jk}, \quad A_{jk} = A_{kj}.$$ 

In addition, we have the structure equations

$$(7.4) \quad d\omega^k_j - \omega^l_j \wedge \omega^k_l = R^k_{lm} \theta^l \wedge \theta^m + W^k_{ji} \theta^j \wedge \theta - W^k_{lj} \theta^j \wedge \theta + i \theta_j \wedge \tau^k - i \tau_j \wedge \theta^k.$$
The pseudohermitian curvature tensor of the Tanaka-Webster connection is the tensor with components \( R_{jklm} \); its Ricci tensor is \( \rho_{jk} := R_{i jk}^{\; i} \) and its scalar curvature is \( \kappa_0 := \rho_{jk}^{\; j} \).

### 7.2. Local pseudohermitian invariants

Let us now define local pseudohermitian invariants. The definition is a bit more complicated than that of a local Riemannian invariants, because:

- The components of the Tanaka-Webster connections and its curvature and torsion tensors are defined with respect to the datum of a local frame \( Z_1, \ldots, Z_n \);
- In order to get local pseudohermitian invariants from pseudohermitian invariant \( \Psi_H \) it is important to take into the tangent group bundle of a CR manifold, in which the Heisenberg group comes into play.

This being said, in order to define local pseudohermitian invariants some notation need to be introduced.

Let \( U \subset \mathbb{R}^n \) be an open of local coordinates equipped with a frame \( Z_1, \ldots, Z_n \) of \( T_{1,0} \). We set \( Z_j = X_j - i X_{n+j} \), where \( X_j \) and \( X_{n+j} \) are real vector fields. Then \( X_0, \ldots, X_{2n} \) is a local \( H \)-frame of \( TM \). We shall call this frame the \( H \)-frame associated to \( Z_1, \ldots, Z_n \).

Let \( \eta^1, \ldots, \eta^{2n} \) be the coframe of \( T^*M \) dual to \( X_0, \ldots, X_{2n} \) (so that \( \eta^0 = \theta \)). We set \( X_j = X_j^k \partial_x^k \) and \( \eta^i = \eta^i_k dx^k \). We also set \( Z_j = Z_j^k \partial_x^k \). It will be convenient to identify \( X_0(x) \) with the vector \( (X_0^k(x)) \in \mathbb{R}^{2n+1} \) and \( Z(x) := (Z_1(x), \ldots, Z_n(x)) \) with the matrix \( (Z_j^k(x)) \) in \( M_{n,2n+1}(\mathbb{C}) \), where the latter denotes the open subset of \( M_{n,2n+1}(\mathbb{C}) \) consisting of regular matrices.

For \( j, k = 1, \ldots, n \) we set \( h_{jk} = h_\theta(Z_j, Z_k) = i \theta([Z_j, Z_k]) \), and for \( j, k = 1, \ldots, 2n \) we set \( L_{jk} = \theta([X_j, X_k]) \). Let \( M_n(\mathbb{C})_+ \) denote the open cone of positive definite Hermitian \( n \times n \) matrices. In the sequel it will also be convenient to identify \( h_\theta \) with the matrix \( h_\theta(x) := (h_{jk}(x)) \in M_n(\mathbb{C})_+ \).

Thanks to the integrability of \( T_{1,0} \) we have \( \theta([Z_j, Z_k]) = 0 \). As we have \( [Z_j, Z_k] = [X_j, X_k] - [X_{n+j}, X_{n+k}] - i([X_{n+j}, X_k] + [X_j, X_{n+k}]) \) we see that

\[
L_{n+j, n+k} = L_{j,k} \quad \text{and} \quad L_{j,n+k} = -L_{n+j,k}.
\]

Since \( [Z_j, Z_k] = [X_j, X_k] + [X_{n+j}, X_{n+k}] + i([X_{n+j}, X_k] - [X_j, X_{n+k}]) \) we get

\[
L_{jk} = \theta([Z_j, Z_k]) = 2i L_{jk} + 2 L_{n+j,k}.
\]

In other words, we have

\[
(L_{jk}) = \frac{1}{2} \begin{pmatrix}
3h & -\bar{\rho}h \\
\bar{\rho}h & 3h
\end{pmatrix}.
\]

For any \( a \in U \) we let \( \psi_a \) be the affine change of variables to the privileged coordinates centered at \( a \) (cf. Definition 5.4). One checks that \( \psi_a(x)^j = \eta^j_k(x^k - a^k) \), so we have

\[
\psi_a X_j = X_j^k(\psi_a(x)) \eta^j_k(a) \partial_k.
\]

Given a vector field \( X \) defined near \( x = 0 \) let us denote \( X(0), \) the vector field obtained as the part in the Taylor expansion at \( x = 0 \) of \( X \) which is homogeneous of
degree \(l\) with respect to the Heisenberg dilations \([5.7]\). Then the Taylor expansions at \(x = 0\) of the vector fields \(\psi_a, X_0, \ldots, \psi_a X_{2n}\) take the form

\[
\begin{align*}
X_0 &= X_0^{(a)} + X_0(0)(-1) + \ldots, \\
X_j &= X_j^{(a)} + X_j(0)(0) + \ldots, \quad 1 \leq j \leq 2n,
\end{align*}
\]

with

\[
X_0^{(a)} = \partial x^a, \quad X_j^{(a)} = \partial x_j + b_{jk}(a)x^k \partial x^\alpha, \quad 1 \leq j \leq 2n,
\]

where we have set \(b_{jk}(a) := \partial [X_j^I(\psi_a(x))]_{x=0} \eta^I(a)\). Notice that \(X_0^{(a)}\) is homogeneous of degree \(-2\), while \(X_1^{(a)}, \ldots, X_{2n}^{(a)}\) are homogeneous of degree \(-1\).

The linear span of the vector fields \(X_0^{(a)}, \ldots, X_{2n}^{(a)}\) is a 2-step nilpotent Lie algebra under the Lie bracket of vector fields. Therefore, this is the Lie algebra of left-invariant vector fields on a 2-step nilpotent Lie group \(G^{(a)}\). The latter can be realized as \(\mathbb{R}^{2n+1}\) equipped with the product,

\[
x, y = (x^0 + y^0 + b_{jk}(a)x^j y^k, x^1 + y^1, \ldots, x^{2n} + y^{2n}).
\]

Notice that \([X^{(a)}, X^{(b)}] = (b_{jk}(a) - b_{jk}(b))X_0^{(a)}\). In addition, we can check that

\[
[\psi_a X_j, \psi_a X_k](0) = [b_{jk}(a) - b_{jk}(b)] \partial x^\alpha \text{ mod } H_0.
\]

Thus,

\[
L_{jk}(a) = \theta(X_j, X_k)(a) = \psi_a \theta([\psi_a X_j, \psi_a X_k](0)) = (\partial x^\alpha, [\psi_a X_j, \psi_a X_k](0)) = b_{jk}(a) - b_{jk}(b).
\]

This shows that \(G^{(a)}\) has the same constant structures as the tangent group \(G, M\), hence is isomorphic to it (see \([5.1]\)). This also implies that \((-\frac{1}{2}L_{jk}(a))\) is the skew-symmetric part of \((b_{jk}(a))\). For \(j, k = 1, \ldots, 2n\) set \(\mu_{jk}(a) = b_{jk}(a) + \frac{1}{2}L_{jk}(a)\). The matrix \((\mu_{jk}(a))\) is the symmetric part of \((b_{jk}(a))\), so it belongs to the space \(S_{2n}(\mathbb{R})\) of symmetric \(2n \times 2n\) matrices with real coefficients.

In the sequel we set

\[
\Omega = M_n(\mathbb{C})_+ \times \mathbb{R}^{2n+1} \times M_{2n, 2n+1}(\mathbb{C})^\times \times S_{2n}(\mathbb{R}).
\]

This is a manifold, and for any \(x \in U\) the quadruple \((h(x), X_0(x), Z(x), \mu(x))\) is an element of \(\Omega\) depending smoothly on \(x\).

In addition, we let \(\mathcal{P}\) be the set of monomials in the undetermined variables \(\partial^\alpha X_0^k, \partial^\alpha Z_j^k\) and \(\partial^\alpha \overline{Z}_j^k\), where the integer \(j\) ranges over \(\{1, \ldots, n\}\), the integer \(k\) ranges over \(\{0, \ldots, 2n\}\), and \(\alpha\) ranges over all multi-orders in \(\mathbb{N}^n_{\geq 0}\). Given the Reeb field \(X_0\) and a local frame \(Z_0, \ldots, Z_n\) of \(T_{1,0}\) by plugging \(\partial^\alpha X_0^k(x), \partial^\alpha Z_j^k(x)\) and \(\partial^\alpha \overline{Z}_j^k(x)\) into a monomial \(p \in \mathcal{P}\) we get a function which we shall denote \(p(X_0, Z, \overline{Z})(x)\).

Bearing all this mind we define local pseudohermitian invariants as follows.

**Definition 7.1.** A local pseudohermitian invariant of weight \(w\) is the datum on each pseudohermitian manifold \((M^{2n+1}, \theta)\) of a function \(I_\theta \in C^\infty(M)\) such that:

1. There exists a finite family \((a_p)_{p \in \mathcal{P}} \subset C^\infty(\Omega)\) such that, in any local coordinates equipped with a frame \(Z_1, \ldots, Z_n\) of \(T_{1,0}\), we have

\[
I_\theta(x) = \sum_{p \in \mathcal{P}} a_p(h(x), X_0(x), Z(x), \mu(x))p(X_0, Z, \overline{Z})(x).
\]

(i) We have \(I_{t\theta}(x) = t^{-w}I_\theta(x)\) for any \(t > 0\).
Any local Riemannian invariant of \( h_\theta \) is a local pseudohermitian invariant. However, the above notion of weight for pseudohermitian invariant is anisotropic with respect to \( h_\theta \). For instance if we replace \( \theta \) by \( t\theta \) then \( h_\theta \) is rescaled by \( t \) on \( T_{1,0} \oplus T_{0,1} \) and by \( t^2 \) on the vertical line bundle \( \mathcal{N} \otimes \mathbb{C} \).

On the other hand, as shown in [JL2 Prop. 2.3] by means of parallel translation along parabolic geodesics any orthonormal frame \( Z_1(a), \ldots, Z_n(a) \) of \( T_{1,0} \) at a point \( a \in M \) can be extended into a local frame \( Z_1, \ldots, Z_n \) of \( T_{1,0} \) near \( a \). Such a frame is called a special orthonormal frame.

Furthermore, as also shown in [JL2 Prop. 2.3] any special orthonormal frame \( Z_1, \ldots, Z_n \) near \( a \) allows us to construct pseudohermitian normal coordinates \( x_0, z^1 = x^1 + ix^{n+1}, \ldots, z^n = x^n + ix_{2n} \) centered at \( a \) in such way that in the notation of (7.10) we have

\[
(7.16) \quad X_0(0) = \partial_{x^0}, \quad Z_j(0) = \partial_{z^j} + \frac{i}{2} z^j \partial_{x^0}, \quad \omega_{j\bar{k}}(0) = 0.
\]

Set \( Z_j = X_j - iX_{n+j} \), where \( X_j \) and \( X_{n+j} \) are real vector fields. Then we have

\[
X_j(0) = \partial_{x^j} - \frac{1}{2} x^{n+j} \partial_{x^0} \quad \text{and} \quad X_{n+j}(0) = \partial_{x^{n+j}} + \frac{1}{2} x^j \partial_{x^0}.
\]

In particular, we have \( X_j(0) = \partial_{x^j} \) for \( j = 0, \ldots, 2n \). This implies that the affine change of variables \( \psi_0 \) to the privileged coordinates at 0 is just the identity. Moreover, in the notation of (7.10) for \( j = 1, \ldots, n \) we have

\[
(7.17) \quad X_j^{(0)} = \partial_{x^j} - \frac{1}{2} x^{n+j} \partial_{x^0}, \quad X_{n+j}^{(0)} = \partial_{x^{n+j}} + \frac{1}{2} x^j \partial_{x^0}.
\]

Incidentally, this shows that the matrix \( (b_{jk}(0)) \) is skew-symmetric, so its symmetric part vanishes, i.e., we have \( \mu(0) = 0 \).

**Proposition 7.2.** Assume that on each pseudohermitian manifold \((M^{2n+1}, \theta)\) there is the datum of a function \( I_\theta \in C^\infty(M) \) such that \( I_{t\theta}(x) = t^{-w} I_\theta(x) \) for any \( t > 0 \). Then the following are equivalent:

(i) \( I_\theta(x) \) is a local pseudohermitian invariant;

(ii) There exists a finite family \( \{a_p\}_{p \in \mathcal{P}} \subset \mathbb{C} \) such that, for any pseudohermitian manifold \((M^{2n+1}, \theta)\) and any point \( a \in M \), in any pseudohermitian normal coordinates centered at \( a \) associated to any given special orthonormal frame \( Z_1, \ldots, Z_n \) of \( T_{1,0} \) near \( a \), we have

\[
(7.18) \quad I_\theta(a) = \sum_{p \in \mathcal{P}} a_p p(X_0, Z, \bar{Z})(x)|_{x=0}.
\]

(iii) \( I_\theta(x) \) is a universal linear combination of complete tensorial contractions of covariant derivatives of the pseudohermitian curvature tensor and of the torsion tensor of the Tanaka-Webster connection.

**Proof.** The proof will consist in proving the implications (iii) ⇒ (i), (i) ⇒ (ii) and (ii) ⇒ (iii). We shall prove them in this order.

First, let \( Z_1, \ldots, Z_n \) be a local frame of \( T_{1,0} \) and let \( \theta^1, \ldots, \theta^n \) be the corresponding coframe of \( T_{1,0} \). Then it follows from (7.3) and (7.4) that in local coordinates the components \( R_{j\bar{k}lm\bar{n}} \) and \( A_{j\bar{k}} \) of its curvature and torsion tensors of the Tanaka-Webster connection with respect to the frame are universal expressions of the form (7.15). Therefore, any linear combination of complete tensorial contractions of covariant derivatives of the curvature and torsion tensors yield a local pseudohermitian invariant. This proves the implication (iii) ⇒ (i).
Second, let \( \mathcal{I}_\theta(x) \) be a local pseudohermitian invariant. Then there exists a finite family \((a_p)_{p \in \mathcal{P}} \subset C^\infty(\Omega)\) such that, in any local coordinates equipped with a frame \(Z_1, \ldots, Z_n\) of \(T_{1,0}\), we have

\[
(7.19) \quad \mathcal{I}_\theta(x) = \sum_{p \in \mathcal{P}} a_p(h(x), X_0(x), Z(x), \mu(x))p(X_0, Z, \overline{Z})(x).
\]

Let \( a \in M \) and let us work in normal pseudohermitian coordinates centered at \( a \) and associated to a special orthonormal frame \( Z_1, \ldots, Z_n \) of \( T_{1,0} \). Since \( Z_1, \ldots, Z_n \) is an orthonormal frame we have \( h_{jk} = \delta_{jk} \). Moreover, by (7.16) we have \( X_0(0) = \partial_{x_0} \) and \( Z_j(0) = \partial_{z_j} \), i.e., \( X_0(0) = (\delta_0^k) \) and \( Z(0) = (\delta_j^k - i\delta_{n+j}^k) \). In addition, by (7.17) we have \( \mu(0) = 0 \). Set \( a_p = a_p((\delta_{jk}), (\delta_0^k), (\delta_j^k - i\delta_{n+j}^k), 0) \). Then by (7.19) we have

\[
(7.20) \quad \mathcal{I}_\theta(a) = \sum_{p \in \mathcal{P}} a_p p(X_0, Z, \overline{Z})(0).
\]

Since the \( a_p \)'s are universal constants this shows that \( \mathcal{I}_\theta \) satisfies (ii). The implication (i) \( \Rightarrow \) (ii) is thus proved.

It remains to prove the implication (ii) \( \Rightarrow \) (iii). To this end assume that there exists a finite family \((a_p)_{p \in \mathcal{P}} \subset \mathbb{C} \) such that, for any pseudohermitian manifold \((M^{2n+1}, \theta)\) and any point \( a \in M \), in any pseudohermitian normal coordinates centered at \( a \) and associated to any given special orthonormal frame \( Z_1, \ldots, Z_n \) of \( T_{1,0} \) near \( a \), we have

\[
(7.21) \quad \mathcal{I}_\theta(a) = \sum_{p \in \mathcal{P}} a_p p(X_0, Z, \overline{Z})(x)|_{x=0}.
\]

In the sequel by order of a differential operator we mean order in the Heisenberg calculus sense, and by polynomial in partial or covariant derivatives of components of some tensors or forms we mean a polynomial in these quantities and their complex conjugates. Bearing this in mind, by [112] Prop. 2.5 in normal pseudohermitian coordinates associated to any given special orthonormal frame \( Z_1, \ldots, Z_n \) of \( T_{1,0} \) with dual coframe \( \theta^1, \ldots, \theta^n \) the following holds:

(a) At \( x = 0 \) the partial derivatives of order \( \leq N \) of the components of the contact form \( \theta \) are universal polynomials in partial derivatives of order \( \leq N \) of the components of the forms \( \theta^j \):

(b) At \( x = 0 \) the partial derivatives of order \( \leq N \) of the components of the forms \( \theta^j \) are universal polynomials in partial derivatives of order \( \leq N \) of the components \( \omega_{jk} \) and \( A_{jk} \) of the connection 1-form and torsion tensor of the Tanaka-Webster connection;

(c) At \( x = 0 \) the partial derivatives of order \( \leq N \) of the components \( \omega_{jk} \) are universal polynomials in partial derivatives of order \( \leq N \) of the components \( R_{jkiln} \) and \( A_{jk} \) of the pseudohermitian curvature tensor and torsion tensor of the Tanaka-Webster connection.

It follows from this that at \( x = 0 \) the partial derivatives of order \( \leq N \) of the components of the vector fields \( X_0, Z_1, \ldots, Z_n \) are universal polynomials in partial derivatives of order \( \leq N \) of the components \( R_{jkiln} \) and \( A_{jk} \) of the pseudohermitian curvature tensor and torsion tensor of the Tanaka-Webster connection. Therefore \( \mathcal{I}_\theta(0) \) is a universal polynomial in partial derivatives at \( x = 0 \) of these components.
Next, by definition the pseudohermitian curvature tensor $R_{jklm}$ is a section of the bundle $\mathcal{T} := \Lambda^{1,0} \otimes \Lambda^{0,1}$. Let $\nabla^T$ be the lift of $\nabla$ to $\mathcal{T}$, so that with respect to the local frame \{ $\theta^{j_1} \otimes \theta^{j_2} \otimes \theta^{j_3} \otimes \theta^{j_4}$ \} of $\mathcal{T}$ we have

\begin{equation}
\nabla^T = d + \omega^{j_1}_{k_1} \otimes 1 \otimes 1 \otimes 1 + 1 \otimes \omega^{j_2}_{k_2} \otimes 1 \otimes 1 + \ldots .
\end{equation}

For $j = 1, \ldots, n$ set $Z_j = X_j - i X_{n+j}$ where $X_j = X_j^k \frac{\partial}{\partial x^k}$ and $X_{n+j} = X_{n+j}^k \frac{\partial}{\partial x^k}$ are real-valued vector fields. An induction then shows that, for any ordered subset $I = (i_1, \ldots, i_N) \subset \{0, \ldots, 2n\}$, we have

\begin{equation}
\nabla^T_{X_{i_1}} \cdots \nabla^T_{X_{i_m}} = X_{j_1}^{j_1} \cdots X_{j_N}^{j_N} \partial_{x^{j_1}} \cdots \partial_{x^{j_N}} + \sum_{|\alpha| \leq N-1} a_{I,\alpha} \theta^{\alpha}_x,
\end{equation}

where the components of $a_{I,\alpha} = (a^{j_1}_{i_1 j_2} a^{j_2}_{i_2 j_3} \cdots a^{j_N}_{i_N})$ with respect to the frame \{ $\theta^{j_1} \otimes \theta^{j_2} \otimes \theta^{j_3} \otimes \theta^{j_4}$ \} are universal polynomials in the partial derivatives of order $\leq N-1$ of the components $X_{j_1}$ and $\omega_{j_2}(X_{i_1})$.

We know that at $x = 0$ the partial derivatives of order $\leq N-1$ of the components $X_{j_1}$ and $\omega_{j_2}(X_{i_1})$ are universal polynomials in partial derivatives of order $\leq N-1$ of the curvature and torsion components $R_{jklm}$ and $A_{jk}$. Moreover (7.16) implies that $X_{j_1}^{j_1} \cdots X_{j_N}^{j_N} \partial_{x^{j_1}} \cdots \partial_{x^{j_N}} (0) = \partial_{x^{j_1}} \cdots \partial_{x^{j_N}}$. Therefore, for any multi-order $\alpha$ in $\mathbb{N}^{2n+1}$ such that $|\alpha| = N$, we have

\begin{equation}
\partial^T_\alpha R_{jklm}(0) = (\nabla^T_{X_{j_1}})^{\alpha_1} \cdots (\nabla^T_{X_{j_N}})^{\alpha_N} R_{jklm}(0) + P_\alpha(R, \tau),
\end{equation}

where $P_\alpha(R, \tau)$ is a universal polynomial in the partial derivatives at $x = 0$ of order $\leq N-1$ of the components of the pseudohermitian curvature tensor and that of the torsion tensor.

On the other hand, as $Z_1, \ldots, Z_n$ is an orthonormal frame we have

\begin{equation}
\theta([Z_j, Z_k]) = -i d\theta(Z_j, Z_k) = -i \delta_{jk},
\end{equation}

Furthermore, from (6.3) we get

\begin{equation}
\theta^l([Z_j, Z_k^l]) = -d\theta^l(Z_j, Z_k) = -\omega^l_j(Z_k).
\end{equation}

Together (7.25) and (7.26) show that

\begin{equation}
[Z_j, Z_k] = -i \delta_{jk} X_0 - \omega^l_j(Z_k) Z_l + \omega^l_k(Z_j) Z_l.
\end{equation}

Combining this with the fact that $[Z_j, Z_j] = 2i [X_j, X_{n+j}]$ we deduce that

\begin{equation}
X_0 = \frac{1}{n} \sum_{j=1}^n \left\{ 2[X_j, X_{n+j}] + i \omega^k_j(Z_j) Z_k - i \omega^k_j(Z_j) Z_k \right\}.
\end{equation}

Thus,

\begin{equation}
\nabla^T_{X_0} = \frac{1}{n} \sum_{j=1}^n \left\{ 2 \nabla^T_{[X_j, X_{n+j}]} + i \omega^k_j(Z_j) \nabla^T_{Z_k} - i \omega^k_j(Z_j) \nabla^T_{Z_k} \right\}.
\end{equation}

Let $R^T$ be the pseudohermitian curvature of $\mathcal{T}$. Its components with respect to the orthonormal frame \{ $\theta^{j_1} \otimes \theta^{j_2} \otimes \theta^{j_3} \otimes \theta^{j_4}$ \} are

\begin{equation}
R^T_{j_1 j_2 j_3 j_4 k_1 k_2 k_3 k_4} = -R^T_{k_1 k_2 k_3 k_4 l m} \otimes 1 \otimes 1 \otimes 1 + 1 \otimes R^T_{j_1 j_2 j_3 j_4 k_1 k_2 l m} \otimes 1 \otimes 1 + \ldots.
\end{equation}
As $R^{\tau}(X_j, X_{n+j}) = \{ \nabla^{\tau}_{X_j}, \nabla^{\tau}_{X_{n+j}} \} - \nabla^{\tau}_{[X_j, X_{n+j}]}$ it follows from (7.29) that $\nabla^{\tau}_{X_0}$ is equal to

$$\frac{1}{n} \sum_{j=1}^{n} \left\{ 2[\nabla^{\tau}_{X_j}, \nabla^{\tau}_{X_{n+j}}] + i\omega^j_k(Z_j)\nabla^{\tau}_{Z_k} - i\omega^k_j(Z_j)\nabla^{\tau}_{Z_k} - 2R^{\tau}(X_j, X_{n+j}) \right\}.$$  

(7.31)

By combining this with (7.24) we then can show that, for any multi-order $\alpha$ in $\mathbb{N}_0^{2n+1}$ such that $|\alpha| = N$, we have

$$\partial^\alpha_{x} R_{jkl\bar{n}}(0) = \left( \left( \frac{2}{n} \sum_{j=1}^{n} [\nabla^{\tau}_{X_j}, \nabla^{\tau}_{X_{n+j}}] \right)^{\alpha} \nabla^{\tau}_{X_\alpha} \cdots (\nabla^{\tau}_{X_{2n}})^{\alpha_{2n}} A \right)(0) + P_{\alpha}(R, \tau),$$

where $P_{\alpha}(R, \tau)$ is a universal polynomial in the partial derivatives at $x = 0$ of order $\leq N - 1$ of the components of the pseudohermitian curvature tensor and that of the torsion tensor.

The tensor $A_{j\bar{k}}$ is a section of the bundle $\mathcal{T}' := \Lambda^{1,0} \otimes \Lambda^{1,0}$. If we let $\nabla^{\mathcal{T}'}$ denote the lift to $\mathcal{T}'$ of the Tanaka-Webster connection then, in the same way as above, we can show that, for any multi-order $\alpha \in \mathbb{N}_0^{2n+1}$ such that $|\alpha| = N$, we have

$$\partial^\alpha_{x} A_{jk}(0) = \left( \left( \frac{2}{n} \sum_{j=1}^{n} [\nabla^{\mathcal{T}'}_{X_j}, \nabla^{\mathcal{T}'}_{X_{n+j}}] \right)^{\alpha} \nabla^{\mathcal{T}'}_{X_\alpha} \cdots (\nabla^{\mathcal{T}'}_{X_{2n}})^{\alpha_{2n}} A \right)(0) + Q_{\alpha}(R, \tau),$$

where $Q_{\alpha}(R, \tau)$ is a universal polynomial in the partial derivatives at $x = 0$ of order $\leq N$ with respect to the vector fields $X_1, \ldots, X_n$.

It follows from all this that $\mathcal{I}_0(0)$ agrees with value at $x = 0$ of a universal polynomial in covariant derivatives of order $\leq N$ of the components of the pseudohermitian curvature tensor and that of the torsion tensor. We then can make use of $U(n)$-invariant theory as in [BCS, pp. 380–382] to deduce that $\mathcal{I}_0(x)$ is a linear combination of complete tensorial contractions of covariant derivatives of these tensors, i.e., $\mathcal{I}_0(x)$ satisfies (iii). This proves that (ii) implies (iii). The proof is thus achieved.  

7.3. Pseudohermitian invariants $\Psi_H$DOs. We define homogeneous symbols on $\Omega \times \mathbb{R}^{2n+1}$ as follows.

**Definition 7.3.** $S_m(\Omega \times \mathbb{R}^{2n+1})$, $m \in \mathbb{C}$, consists of be functions $a(h, X_0, Z, \xi)$ in $C^\infty(\Omega \times (\mathbb{R}^{2n+1} \setminus 0))$ such that $a(\theta, Z, t\xi) = t^m a(\theta, Z, \xi)$ for $t > 0$.

In addition, recall that if $Z_1, \ldots, Z_n$ is a local frame of $T_{1,0}$ then its associated $H$-frame is the frame $X_0, \ldots, X_{2n}$ of $TM$ such that $Z_j = X_j - iX_{n+j}$ for $j = 1, \ldots, n$.

**Definition 7.4.** A pseudohermitian invariant $\Psi_H$DO of order $m$ and weight $w$ is the datum on each pseudohermitian manifold $(M^{2n+1}, \theta)$ of an operator $P_0$ in $\Psi^w_H(M)$ such that:

(i) For $j = 0, 1, \ldots$ there exists a finite family $(\alpha_{j\bar{p}})_{\bar{p} \in \mathcal{P}} \subset S_{m-j}(\Omega \times \mathbb{R}^{2n+1})$ such that, in any local coordinates equipped with the $H$-frame associated to a frame
\[ Z_1, \ldots, Z_n \text{ of } T_{1,0}, \text{ the operator } P_\theta \text{ has symbol } p_\theta = \sum p_{\theta, m-j} \text{ with } \]
\[ p_{\theta, m-j}(x, \xi) = \sum_{p \in P} p(X_0, Z, \overline{Z})(x) a_{j,p}(h(x), X_0(x), Z(x), \mu(x), \xi). \]

(ii) For any \( t > 0 \) we have \( P_{t \theta} = t^{-w} P_\theta \text{ modulo } \Psi^{-\infty}(M). \)

In addition, we will say that \( P_\theta \) is admissible if in (7.34) we can take \( a_{0p}(h, X_0, Z, \mu, \xi) \) to be zero for \( p \neq 1 \).

Before proving the analogues in pseudohermitian geometry of Proposition 3.3 and Proposition 3.4, we need to recall some results about the symbolic calculus for \( \Psi_H \) DOs.

Given a matrix \( b = (b_{ij}) \in M_{2n}(\mathbb{R}) \) we can endow \( \mathbb{R}^{2n+1} \) with a structure of 2-step nilpotent Lie group by means of the product,
\[ x,y = (x^0 + y^0 + b_{ij} x^i y^j, x^1 + y^1, \ldots, x^{2n} + y^{2n}). \]

It follows from [BGr] that under the inverse Fourier transform the convolution for distributions with respect to this group gives rise to a product for homogeneous symbols,
\[ *^b : S_{m_1}(\mathbb{R}^{2n+1}) \times S_{m_2}(\mathbb{R}^{2n+1}) \longrightarrow S_{m_1+m_2}(\mathbb{R}^{2n+1}). \]

Furthermore, this product depends smoothly on \( b \).

Let \( U \subset \mathbb{R}^{2n+1} \) be an open of local coordinates equipped with a \( H \)-frame \( X_0, \ldots, X_d \). We let \( \eta_1^{\prime}, \ldots, \eta_2^{\prime} \) be the dual coframe and we set \( X_j = X_j^k \partial_{x^k} \) and \( \eta_j = \eta_j^k dx^k. \)

For any \( a \in U \) we let \( \psi_\alpha \) be the affine change of variables to the privileged coordinates centered \( a \), and we let \( X_0^{(a)}, \ldots, X_d^{(a)} \) be the model vector fields as defined in (7.11), that is, we have \( X_0^{(a)} = \partial_{x^0} \) and \( X_j^{(a)} = \partial_{x^j} + b_{jk}(a) x^k \partial_{x^0} \) where \( b_{jk}(a) := L_{jk}(a) + \mu_{jk}(a) \). As alluded to before the linear span of the vector fields \( X_0^{(a)}, \ldots, X_d^{(a)} \) is a 2-step nilpotent Lie algebra whose corresponding Lie group is isomorphic to the tangent group \( G_a M \) and can be realized as \( \mathbb{R}^{2n} \) equipped with the group law (7.39) with \( b_{jk} = b_{jk}(a) \). Since the product (7.36) for homogenous symbols on \( \mathbb{R}^{2n} \) depends smoothly on \( b \) and \( b(a) := (b_{jk}(a)) \) depends smoothly on \( a \), we get the following product for homogeneous symbols on \( U \times \mathbb{R}^{2n+1} \),
\[ * : S_{m_1}(U \times \mathbb{R}^{2n+1}) \times S_{m_2}(U \times \mathbb{R}^{2n+1}) \longrightarrow S_{m_1+m_2}(U \times \mathbb{R}^{2n+1}), \]

(7.38) \[ p_{m_1} * p_{m_2}(a, \xi) := [p_{m_1}(a, \cdot) \ast^{b(a)} p_{m_2}(a, \cdot)](\xi) \quad \forall p_j \in S_{m_j}(U \times \mathbb{R}^{2n+1}). \]

We also can define a product for homogeneous symbols on \( \Omega \times \mathbb{R}^{2n+1} \) as follows. For any \( (h, \mu) \) in \( M_n(\mathbb{C})_+ \times S_{2n}(\mathbb{R}) \) we let
\[ b(h, \mu) := \frac{1}{2} L + \mu, \quad L = \frac{1}{2} \begin{pmatrix} \Im h & -\Re h \\ \Re h & \Im h \end{pmatrix}. \]

As \( b(h, \mu) \) depends smoothly on \( (h, \mu) \) we obtain the bilinear product,
\[ * : S_{m_1}(\Omega \times \mathbb{R}^{2n+1}) \times S_{m_2}(\Omega \times \mathbb{R}^{2n+1}) \longrightarrow S_{m_1+m_2}(\Omega \times \mathbb{R}^{2n+1}), \]

such that, for any symbols \( p_1 \in S_{m_1}(\Omega \times \mathbb{R}^{2n+1}) \) and \( p_2 \in S_{m_2}(\Omega \times \mathbb{R}^{2n+1}) \), on \( \Omega \times \mathbb{R}^{2n+1} \) we have
\[ p_{m_1} * p_{m_2}(h, X_0, Z, \mu, \xi) = [p_{m_1}(h, X_0, Z, \mu, \cdot) \ast^{b(h,\mu)} p_{m_2}(h, X_0, Z, \mu, \cdot)](\xi). \]
Observe that it follows from (7.47) and from the very definition of \( \mu(a) \) that we have \( b(x) = \frac{1}{L(x)} + \mu(x) = b(h(x), \mu(x)) \). Therefore, we see that, for any symbols \( p_1 \in S_{m_1}(\Omega \times \mathbb{R}^{2n+1}) \) and \( p_2 \in S_{m_2}(\Omega \times \mathbb{R}^{2n+1}) \), on \( U \times \mathbb{R}^{2n+1} \) we have

\[
(7.42) \quad [p_{m_1}(h(x), X_0(x), Z(x), \mu(x), \xi)] * [p_{m_2}(h(x), X_0(x), Z(x), \mu(x), \xi)] = (p_{m_1} * p_{m_2})(h(x), X_0(x), Z(x), \mu(x), \xi),
\]

where the product * on the l.h.s. is that for homogeneous symbols on \( U \times \mathbb{R}^{2n+1} \) and the other product * is that for homogeneous symbols on \( \Omega \times \mathbb{R}^{2n+1} \).

Next, let \( \sigma_j(x, \xi) = X_j^k(x) \xi_k \) be the classical symbol of \( \frac{1}{L} X_j \). Then the symbol of \( \psi_a \ast \sigma_j(x, \xi) \) is \( \psi_a \ast \sigma_j(x, \xi) := X_j^k(\psi_a(x)) \eta_j^l(a) \xi_l \). We set \( \sigma(x, \xi) = (\sigma_0(x, \xi), \ldots, \sigma_{2n}(x, \xi)) \). Similarly, we let \( \sigma^{(a)}(x, \xi) \) be the classical symbol of \( \frac{1}{L} X_j^{(a)} \) and we set \( \sigma^{(a)}(x, \xi) = (\sigma_0(x, \xi), \ldots, \sigma_{2n}(x, \xi)) \). Notice that \( \sigma_0^{(a)}(x, \xi) = \xi_0 \), while for \( j = 1, \ldots, 2n \) we have \( \sigma_j^{(a)}(x, \xi) = \xi_j + b_{jk}(a) x^k \xi_0 \). For any multi-order \( \beta \in \mathbb{N}_0^{2n} \) we can write

\[
(7.43) \quad [\psi_a \ast \sigma(x, \xi) - \sigma^{(a)}(x, \xi)]^\beta = \sum_{|\gamma| = |\beta|} e_{\beta \gamma}(a, x) \sigma^{(a)}(x, \xi)^\gamma,
\]

where the coefficients \( e_{\beta \gamma}(a, x) \) are smooth functions on \( U \times \mathbb{R}^{2n+1} \). We then let \( h_{\alpha \beta \gamma \delta}(a) \) be the smooth function on \( U \) given by

\[
(7.44) \quad h_{\alpha \beta \gamma \delta}(a) = \frac{1}{\alpha! \beta! \gamma! \delta!} \partial_{\xi}^{\alpha} \eta_\gamma^l(a) e_{\beta \gamma}(a, x) \big|_{x = 0}.
\]

**Proposition 7.5** ([BGR Thm. 14.7]). Let \( P \in \Psi^m_H(U) \) have symbol \( p \sim \sum p_{m-j} \), let \( Q \in \Psi^m_H(U) \) have symbol \( q \sim \sum q_{m'-j} \), and assume that \( P \) or \( Q \) is properly supported. Then \( PQ \) belongs to \( \Psi^{m+m'}_H(U) \) and has symbol \( r \sim \sum r_{m+m'-j} \) with

\[
(7.45) \quad r_{m+m'-j} = \sum_{(j)} h_{\alpha \beta \gamma \delta}(D^{\delta}_{\xi} p_{m-k}) * (\xi^\gamma \partial^\alpha_{\xi} D^\beta_{\xi} q_{m'-l}),
\]

where \( \sum_{(j)} \) denotes the summation over all indices such that \( |\gamma| = |\beta| \) and \( |\beta| + |\alpha| \leq |\delta| + |\gamma| = j - k - l \).

Bearing all this in mind we are now ready to prove:

**Proposition 7.6.** Let \( P_0 \) be a pseudohermitian invariant \( \Psi_H DO \) of order \( m \) and weight \( w \), let \( Q_0 \) be a pseudohermitian invariant \( \Psi_H DO \) of order \( m' \) and weight \( w' \), and assume that \( P_0 \) or \( Q_0 \) is uniformly properly supported. Then:

1) \( P_0 Q_0 \) is a pseudohermitian invariant \( \Psi_H DO \) of order \( m + m' \) and weight \( w + w' \).

2) If \( P_0 \) and \( Q_0 \) are admissible, then \( P_0 Q_0 \) is admissible as well.

**Proof.** Since \( P_0 \) and \( Q_0 \) are pseudohermitian invariant \( \Psi_H DOs \), for \( j = 0, 1, \ldots \), there exist finite families \( (a_{jp})_{p \in P} \subset S_{m-j}(\Omega \times \mathbb{R}^{2n+1}) \) and \( (b_{jq})_{q \in P} \subset S_{m'-j}(\Omega \times \mathbb{R}^{2n+1}) \) such that, in any given local coordinates equipped with the \( H \)-frame associated to a frame \( Z_1, \ldots, Z_n \) of \( T_{1,0} \), the respective symbols of \( P_0 \) and \( Q_0 \) are \( p \sim \sum p_{\theta, m-j} \) and \( q \sim \sum q_{\theta, m'-j} \) with

\[
(7.46) \quad p_{\theta, m-j}(x, \xi) = \sum_{p \in P} p(X_0, Z, Z)(x) a_{jp}(h(x), X_0(x), Z(x), \mu(x), \xi),
\]

\[
(7.47) \quad q_{\theta, m'-j}(x, \xi) = \sum_{q \in P} q(X_0, Z, Z)(x) b_{jq}(h(x), X_0(x), Z(x), \mu(x), \xi).
\]
Therefore, by Proposition 7.3, the operator $P_0 Q_\theta$ has symbol $r \sim \sum r_{m+m'-j}(x, \xi)$ equal to

$$
(7.48) \quad \sum_{p,q \in P} \sum_j h_{\alpha\beta\gamma}(x)p(X_0, Z, \bar{Z})(x)[D^\beta_{\xi_k} a_{kp}(h(x), X_0(x), Z(x), \mu(x), \xi)]^* \nonumber
\left[\xi^\gamma D^\beta_{\xi_k} \partial_x^s (q(X_0, Z, \bar{Z}))(x) b_{lq}(h(x), X_0(x), Z(x), \mu(x), \xi)\right].
$$

Notice that, given a multi-order $\alpha \in \mathbb{N}_0^{2n+1}$, for any monomial $q \in P$ and any symbol $b \in S_m(\Omega \times \mathbb{R}^{2n+1})$ there exists a universal finite family $(C_{\alpha q}(q, b))_{\alpha \in P}$ contained in $S_m(\Omega \times \mathbb{R}^{2n+1})$ such that

$$
(7.49) \quad \partial_x^s [q(X_0, Z, \bar{Z})(x)] b(h(x), X_0(x), Z(x), \mu(x), \xi) = \sum_{\alpha \in P} \hat{q}(X_0, Z, \bar{Z})(x) C_{\alpha q}(q, b)(h(x), X_0(x), Z(x), \mu(x), \xi).
$$

In addition, it follows from the very definition of the function $h_{\alpha\beta\gamma}(x)$ that there exists a universal finite family $(h_{\alpha\beta\gamma}(x) \alpha \in P)$ in $C^\infty(\Omega)$ such that

$$
(7.50) \quad h_{\alpha\beta\gamma}(x) \equiv \sum_{\alpha \in P} h_{\alpha\beta\gamma}(h(x), X_0(x), Z(x), \mu(x)) t(X_0, Z, \bar{Z}),(x).
$$

Now, by combining (7.42), (7.49), (7.50) and (7.51) together we deduce that

$$
(7.51) \quad r_{m+m'-j}(x, \xi) = \sum_{s \in P} s(X_0, Z, \bar{Z})(x) c_{js}(h(x), X_0(x), Z(x), \mu(x), \xi),
$$

where $(c_{js})_{s \in P}$ is the finite family with values in $S_{m+m'-j}(\Omega \times \mathbb{R}^{2n+1})$ given by

$$
(7.52) \quad c_{js} = \sum_{p,q, q \in P} \sum_j h_{\alpha\beta\gamma}(x) h_{\alpha\beta\gamma} D^\beta_{\xi_k} a_{kp}^* [\xi^\gamma D^\beta_{\xi_k} C_{\alpha q}(q, b_{lq})].
$$

Since the family $(c_{js})_{s \in P}$ is independent of the choice of the local coordinates and of the local frame $Z_1, \ldots, Z_n$ this proves that $P_0 Q_\theta$ is pseudohermitian invariant. Furthermore, as for any $t > 0$ we have $P_0 Q_\theta = t^{-(w+w')} P_0 Q_\theta$ modulo $\Psi^{-\infty}(M)$, we see that $P_0 Q_\theta$ is a pseudohermitian invariant $\Psi_H$ DO of weight $w$.

Finally, assume further that $P_0$ and $Q_\theta$ are admissible, that is, there exist symbols $a_m \in S_m(\Omega \times \mathbb{R}^{2n+1})$ and $b_m' \in S_{m'}(\Omega \times \mathbb{R}^{2n+1})$ such that, in any given local coordinates equipped with the $H$-frame associated to a frame $Z_1, \ldots, Z_n$, the principal symbol of $P_0$ is $p_m(x, \xi) = a_m(h(x), X_0(x), Z(x), \mu(x), \xi)$ and the principal symbol of $Q_\theta$ is $q_{m'}(x, \xi) = b_m'(h(x), X_0(x), Z(x), \mu(x), \xi)$. It then follows from Proposition 7.5 and (7.42) that in these local coordinates the principal symbol of $P_0 Q_\theta$ is equal to

$$
p_{m'} q_{m'}(x, \xi) = [a_m(h(x), X_0(x), Z(x), \mu(x), \xi)] [b_{m'}(h(x), X_0(x), Z(x), \mu(x), \xi)] = [a_m * b_{m'}](h(x), X_0(x), Z(x), \mu(x), \xi).
$$

Since the symbol $a_m * b_{m'} \in S_{m+m'}(\Omega \times \mathbb{R}^{2n+1})$ does not depend on the choices of the local coordinates and of the local frame $Z_1, \ldots, Z_n$, this shows that $P_0 Q_\theta$ is admissible. The proof is now complete. $\square$

In order to deal with parametrices of pseudohermitian invariant $\Psi_H$ DOs we need the following lemma.
Lemma 7.7. Let \((h, X_0, Z, \mu) \in \Omega\). Then we can endow \(\mathbb{R}^{2n+1}\) with a pseudohermitian structure and a global frame \(Z_1, \ldots, Z_n\) of \(T_{1,0}\) with respect to which we have \((h(0), X_0(0), Z(0), \mu(0)) = (h, X_0, Z, \mu)\).

Proof. Let \(L = (L_{jk}) \in M_{2n}(\mathbb{R})\) be the skew-symmetric matrix given by \((7.39)\), and let us endow \(\mathbb{R}^{2n+1}\) with the group law \((7.38)\) corresponding to \(b := b(h, \mu) = \mu + \frac{1}{2} L\). Set \(X^{(0)}_0 = \partial_x\) and \(X^{(0)}_j = \partial_{x^j} + b_{jk} x^k \partial_{x^0}, j = 1, \ldots, 2n\). Let \(H^{(0)} \subset T\mathbb{R}^{2n+1}\) be the hyperplane bundle spanned by the vector fields \(X^{(0)}_1, \ldots, X^{(0)}_n\), and let us endow it with the almost complex structure \(J^{(0)} \in C^\infty(\mathbb{R}^{2n+1}, \text{End} \ H)\) such that for \(j = 1, \ldots, n\) we have \(J^{(0)} X^{(0)}_j = X^{(0)}_{n+j}\) and \(J^{(0)} X^{(0)}_{n+j} = -X^{(0)}_j\).

Observe that the subbundle \(T^{(0)}_{1,0} := \ker(J^{(0)} + i)\) is spanned by the vector fields \(Z_j := X^{(0)}_j - iX^{(0)}_{n+j}, j = 1, \ldots, n\). By \((7.13)\) we have

\[
(7.53) \quad [X^{(0)}_j, X^{(0)}_k] = (b_{kj} - b_{jk}) X^{(0)}_0 = L_{kj} X^{(0)}_0.
\]

Moreover, as the definition \((7.39)\) of \(L\) implies that it satisfies \((7.6)\), we get

\[
(7.54) \quad [Z^{(0)}_j, Z^{(0)}_k] = [(L_{jk} - L_{n+j+n+k}) - i(L_{jn+k} + L_{n+jk})] X^{(0)}_0 = 0.
\]

This implies that \(T^{(0)}_{1,0}\) is integrable in Fröbenius’ sense, so \((H^{(0)}, J^{(0)})\) defines a CR structure on \(\mathbb{R}^{2n+1}\).

Set \(\theta^{(0)} = dx^0 - b_{jk} x^k dx^j\). Then we have \(\theta^{(0)}(X_0) = 1\) and for \(j = 1, \ldots, 2n\), we have \(\theta^{(0)}(X_j) = 0\), so \(\theta^{(0)}\) is a non-vanishing 1-form annihilating \(H^{(0)}\). Moreover, it follows from \((7.39)\) and \((7.53)\) that we have

\[
(7.55) \quad \theta^{(0)}([Z^{(0)}_j, Z^{(0)}_k]) = (L_{jk} + L_{n+j+n+k}) + i(-L_{jn+k} + L_{n+jk}) = h_{jk}.
\]

Since \(h\) is positive definite this shows that the Levi form associated to \(\theta^{(0)}\) is positive definite everywhere. Therefore, the CR structure of \(\mathbb{R}^{2n+1}\) is strictly pseudoconvex and \(\theta^{(0)}\) is a pseudohermitian contact form. In addition, for \(j = 0, \ldots, 2n\) we have \([X^{(0)}_0, X^{(0)}_j] = 0\), so we have \(i X_0 \theta^{(0)}(X_j) = -\theta^{(0)}([X_0, X_j]) = 0\). As we know that \(\theta^{(0)}(X_0) = 1\) it follows that \(X_0\) is the Reeb field of the contact form \(\theta^{(0)}\).

Next, let us write \(X_0 = (X^{(0)}_0, Z)\) and \(\mathcal{X} = (Z^{(0)}_j)\), where \(X_0\) and \(Z\) are the 2nd and 3rd components of our initial element \((h, X_0, Z, \mu) \in \Omega\). Set \(\mathcal{X}^{k} = \mathcal{X}^{(k)} - i\mathcal{X}^{k+n+1}\) with \(\mathcal{X}^{(k)}\) and \(\mathcal{X}^{(k)+}\) in \(\mathbb{R}\), and let \(\psi\) be the unique linear change of variables such that for \(j = 0, \ldots, 2n\) the tangent map \(\psi'(0) : T_0 \mathbb{R}^{2n+1} \rightarrow T_0 \mathbb{R}^{2n+1}\) maps \(\mathcal{X}^{(k)} \partial_{x^k}\) to \(\partial_{x^j}\). Set \(H = \psi^* H^{(0)}\) and \(J = \psi^* J^{(0)}\). Then \((H, J)\) defines a strictly pseudoconvex CR structure on \(\mathbb{R}^{2n+1}\) with respect to which \(\theta := \psi^* \theta^{(0)}\) is a pseudohermitian contact form with Reeb field \(X_0 := \psi^* X^{(0)}_0\). Moreover, as we have \(X^{(0)} = \partial_{x^0}\) we see that \(X_0(0) = \psi'(0)^{-1}(\partial_{x^0}) = X^{(0)}_0\).

The corresponding bundle of \((1,0)\)-vectors is \(T_{1,0} := \psi^* T_{1,0}\). A global frame for this bundle is provided by the vector fields \(Z_j := \psi^* Z^{(0)}_j\). Moreover, it follows from \((7.55)\) that with respect to this frame the matrix of the Levi form associated to \(\theta\) is \((h_{jk})\). In particular, we have \(h(0) = h\). In addition, as \(Z^{(0)}_j = \psi^{(0)}(0) - i X^{(0)}_{n+j} \partial_{x^j} - i \partial x^{n+1}\) we also see that \(Z^{(0)}_j = \psi'(0)^{-1}(\partial_{x^j}) - i \psi'(0)^{-1}(\partial_{x^{n+1}}) = X_j - i \mathcal{X}^{(k)}_j = Z_j\). Thus \(Z(0) = Z\).
In order to complete the proof it remains to check that $\mu(0) = \mu$. For $j = 1, \ldots, 2n$ set $X_j = \psi^* X_j^{(0)}$. Then $X_0, \ldots, X_{2n}$ is a global $H$-frame of $\mathbb{R}^{2n+1}$. Moreover, as $\psi$ is a linear map and for $j = 0, \ldots, 2n$ we have $\psi_* X_j(0) = X_j^{(0)}(0) = \partial_{x^j}$, we see that $\psi$ is the affine change of variables to the privileged coordinates centered at the origin. In addition, since we have $\psi_* X_j = X_j^{(0)}$ and the vector fields $X_j^{(0)}$ are homogeneous, we deduce that $X_j^{(0)}$ is the model vector field of $X_j$ in the sense of (7.9)-(7.11). As we have $X_j^{(0)} = \partial_{x^j} + b_{jk} x^k \partial_{\theta^k}$ we see that $b(0) = (b_{jk}) = b(h, \mu)$. Since by definition $\mu(0)$ is the symmetric part of $b(0)$ and $b(h, \mu)$ has $\mu$ as symmetric part, it follows that $\mu(0) = \mu$ as desired. The proof is thus achieved. □

**Proposition 7.8.** Let $P_0$ be a pseudohermitian invariant $\Psi_H DO$ of order $m$ and weight $w$ such that $P_0$ is admissible and its principal symbol is invertible in the Heisenberg calculus sense. For each pseudohermitian manifold $(M^{2n+1}, \theta)$ let $Q_0$ be a parametrix for $P_0$ in $\Psi_H^{-m}(M)$. Then $Q_0$ is a pseudohermitian invariant $\Psi_H DO$ of order $-m$ and weight $-w$.

**Proof.** First, as $P_0$ is an admissible pseudohermitian invariant $\Psi_H DO$ there exists a symbol $a_m \in S_m(\Omega \times \mathbb{R}^{2n+1})$ such that, in any local coordinates equipped with the $H$-frame associated to a frame $Z_1, \ldots, Z_n$ of $T_{1,0}$, the principal symbol of $P_0$ in these local coordinates is $p_{\theta,m}(x, \xi) := a_m(h(x), X_0(x), Z(x), \mu(x), \xi)$. The fact that the principal symbol of $P_0$ is invertible in the Heisenberg calculus sense means that $p_{\theta,m}$ is invertible with respect to the product (7.33). Therefore, we see that, for any local coordinates equipped with a frame $Z_1, \ldots, Z_n$ of $T_{1,0}$ and for any $x$ in their range, the symbol $a_m(h(x), X_0(x), Z(x), \mu(x), \xi)$ is invertible with respect to the product $b(x) = b(h(x), \mu(x))$. We then can make use of Lemma 7.7 to conclude that for any $(h, X_0, Z, \mu) \in \Omega$ the symbol $a_m(h, X, Z, \mu, \xi)$ is invertible with respect to the product $b(h, \mu)$. Thus, for any $(h, X_0, Z, \mu) \in \Omega$ there exists a symbol $b_{-m}(h, X_0, Z, \mu)(\xi)$ in $S_{-m}(\mathbb{R}^{2n+1})$ such that

$$a_m(h, X_0, Z, \mu, \xi) * b_{-m}(h, X_0, Z, \mu) = b_{-m}(h, X_0, Z, \mu, \xi) * b(h, \mu) a_m(h, X_0, Z, \mu, \xi) = 1. \quad (7.56)$$

Since $a_m(h, X_0, Z, \mu, \xi)$ depends smoothly on $((h, X_0, Z, \mu))$ it follows from [Po2, Prop. 3.3.22] that $b_{-m}(h, X_0, Z, \mu)$ depends smoothly on $((h, X_0, Z, \mu))$ as well. Therefore, we define a symbol $b_{-m} \in S_{-m}(\Omega \times \mathbb{R}^{2n+1})$ by letting

$$b_{-m}(h, X_0, Z, \mu, \xi) := b_{-m}(h, X_0, Z, \mu)(\xi) \quad \forall (h, X_0, Z, \mu, \xi) \in \Omega \times \mathbb{R}^{2n+1}. \quad (7.57)$$

In view of the definition of the product (7.41) we have $a_m * b_{-m} = b_{-m} * a_m = 1$. By combining this with (7.42) we then see that, in any local coordinates equipped with the $H$-frame associated to a frame $Z_1, \ldots, Z_n$ of $T_{1,0}$, the symbol $q_{-m}(x, \xi) := b_{-m}(h(x), X_0(x), Z(x), \mu(x), \xi)$ is the inverse of $p_{\theta,m}$ with respect to the product (7.33).

Next, without any loss of generality we may assume that $Q_0$ is properly supported. Let $p(x, \xi) \sim \sum p_{\theta,m} z^j(x, \xi)$ and $q(x, \xi) \sim \sum q_{-m} z^j(x, \xi)$ be the respective symbols of $P_0$ and $Q_0$ with respect to local coordinates equipped with the $H$-frame associated to a frame $Z_1, \ldots, Z_n$ of $T_{1,0}$. As $P_0 Q_0 = 1$ mod $\Psi^{-\infty}(M)$, from (7.45)
we get
\[
\begin{align*}
(7.58) & \quad p_{\theta, m}q_{-m} = 1, \\
(7.59) & \quad p_{\theta, m} * q_{-m-j} + \sum_{l<j}^{(j)} h_{\alpha \beta \gamma \delta} (D^\delta_{\xi} p_{\theta, m-k}) * (\xi^\gamma \partial_x^\alpha D^\beta_{\xi} q_{-m-l}) = 0 \quad j \geq 1.
\end{align*}
\]

Therefore, we obtain
\[
\begin{align*}
(7.60) & \quad q_{-m}(x, \xi) = b_{-m}(h(x), X_0(x), Z(x), \mu(x), \xi), \\
(7.61) & \quad q_{-m-j} = -q_{-m} * \left[ \sum_{l<j}^{(j)} h_{\alpha \beta \gamma \delta} (D^\delta_{\xi} p_{\theta, m-k}) * (\xi^\gamma \partial_x^\alpha D^\beta_{\xi} q_{-m-l}) \right]
\end{align*}
\]

Now, as \( P_\theta \) is a pseudohermitian invariant \( \Psi_H DO \) for \( j = 1, 2, \ldots \) there exists a finite family \( (a_{jp})_{p \in \mathcal{P}} \subset S_{m-j}(\Omega \times \mathbb{R}^{2n+1}) \) such that, in any local coordinates equipped with the \( H \)-frame associated to a frame \( Z_1, \ldots, Z_n \) of \( T_{1,0} \), we have
\[
\begin{align*}
(7.62) & \quad p_{\theta, m-j}(x, \xi) = \sum_{p \in \mathcal{P}} p(X_0, Z, Z)(x) a_{jp} (h(x), X_0(x), Z(x), \mu(x), \xi).
\end{align*}
\]

Then by using similar arguments as that of the proof of Proposition 7.6 we can show by induction that, for \( j = 0, 1, \ldots \) there exists a finite family \( (\tilde{c}_{js})_{s \in \mathcal{P}} \) contained in \( S_{m-j}(\Omega \times \mathbb{R}^{2n+1}) \) such that
\[
\begin{align*}
(7.63) & \quad q_{-m-j} = \sum_{s \in \mathcal{P}} s(X_0, Z, Z)(x) \tilde{c}_{js} (h(x), X_0(x), Z(x), \mu(x), \xi),
\end{align*}
\]

where, with the notation of 7.52, the families \( (\tilde{c}_{js})_{s \in \mathcal{P}} \) are given by the recursive formulas,
\[
\begin{align*}
(7.64) & \quad \tilde{c}_{01} = b_{-m}, \quad \tilde{c}_{0s} = 0 \quad \text{for} \ s \neq 1, \\
(7.65) & \quad \tilde{c}_{js} = -b_{-m} * \left[ \sum_{p, q, \xi, \varepsilon, r \in \mathcal{P}} \sum_{l<j}^{(j)} h_{\alpha \beta \gamma \delta} (D^\delta_{\xi} a_{\varepsilon p}) * (\xi^\gamma \partial_x^\alpha D^\beta_{\xi} c_{\alpha q}(q, \tilde{c}_{q})) \right] \quad j \geq 0.
\end{align*}
\]

Since the families \( (\tilde{c}_{js})_{s \in \mathcal{P}} \) don’t depend on the local coordinates, this shows that \( Q_\theta \) is a pseudohermitian invariant \( \Psi_H DO \).

Finally, let \( t > 0 \). As \( P_\theta = t^{-w} P_\theta \) modulo \( \Psi^{-\infty}(M) \) we see that \( t^w Q_\theta \) is a parametrix for \( P_\theta \), and so we have \( Q_\theta = t^w Q_\theta \) modulo \( \Psi^{-\infty}(M) \). This completes the proof that \( Q_\theta \) is a pseudohermitian invariant \( \Psi_H DO \) of weight \( w \).

We are now ready to prove the main result of this section.

**Proposition 7.9.** Let \( P_\theta \) be a pseudohermitian invariant \( \Psi_H DO \) of order \( m \) and weight \( w \)

1) The logarithmic singularity \( c_{P_\theta}(x) \) takes the form
\[
(7.66) \quad c_{P_\theta}(x) = \mathcal{I}_\theta(x) |d\theta^m \wedge \theta|,
\]
where \( \mathcal{I}_\theta(x) \) is a local pseudohermitian invariant of weight \( n + 1 + w \).

2) Assume that \( P_\theta \) is admissible and its principal symbol is invertible in the Heisenberg calculus sense. Then the Green kernel logarithmic singularity of \( P_\theta \) takes the form
\[
(7.67) \quad \gamma_{P_\theta}(x) = \mathcal{J}_\theta(x) |d\theta^m \wedge \theta|,
\]
where \( \mathcal{F}_P(x) \) is a local pseudohermitian invariant of weight \( n + 1 - w \).

**Proof.** Set \( c_{P_0}(x) = \mathcal{I}_P(x)|d\theta^n \wedge \theta| \), so that \( \mathcal{I}_P(x) \) is a smooth function on \( M \). For any \( t > 0 \) we have \( c_{P_0}(x) = c_{t^{-w}P_0}(x) = t^{-w}c_{P_0}(x) \) and \( d(t\theta)^n \wedge (t\theta) = t^{n+1}d\theta^n \wedge \theta \), so we see that

\[
\mathcal{I}_{tP_0}(x) = t^{-(w+n+1)}\mathcal{I}_{P_0}(x) \quad \forall t > 0.
\]

Next, by (5.14) in local coordinates equipped with the \( H \)-frame \( X_0, \ldots, X_{2n} \) associated to a local frame \( Z_1, \ldots, Z_n \) of \( T_{1,0} \) we have

\[
c_{P_0}(x) = |\psi'_x|(2\pi)^{-(2n+1)} \left( \int_{\|\xi\|=1} p_{\theta,-(2n+2)}(x, \xi) \epsilon E d\xi \right) dx,
\]

where \( p_{\theta,-(2n+2)} \) is the symbol of degree \(-(2n + 2)\) of \( P_0 \) in these local coordinates.

Furthermore, since \( P_0 \) is a pseudohermitian invariant \( \Psi_H \) DO there exists a finite family \( (a_p)_{p \in \mathcal{P}} \subset S_{-(2n+2)}(\Omega \times \mathbb{R}^{2n+1}) \) such that

\[
p_{\theta,-(2n+2)}(x, \xi) = \sum_{p \in \mathcal{P}} p(X_0, Z, \bar{Z})(x)a_p(h(x), X_0(x), Z(x), \mu(x), \xi).
\]

Therefore, we see that

\[
c_{P_0}(x) = \left( \sum_{p \in \mathcal{P}} p(X_0, Z, \bar{Z})(x)A_p(h(x), X_0(x), Z(x), \mu(x)) \right)|\psi'_x| dx,
\]

where \( A_p \) is the function in \( C^\infty(\Omega) \) defined by

\[
A_p(h, X_0, Z, \mu) = (2\pi)^{-(2n+1)} \left( \int_{\|\xi\|=1} a_p(h, X_0, Z, \mu, \xi) \epsilon E d\xi \right).
\]

Let \( \theta^1, \ldots, \theta^n \) be the coframe of \( \Lambda^{1,0} \) dual to \( Z_1, \ldots, Z_n \), and let \( \eta^0, \ldots, \eta^{2n} \) be the coframe of \( T^*M \) dual to \( X_0, \ldots, X_{2n} \). Notice that \( \eta^0 = \theta \) and \( \theta^1 = \frac{1}{2}(\eta^0 + i\eta^{n+1}) \).

Moreover, we have \( d\theta = i\theta h_{jk}\theta^j \wedge \theta^k \). Thus,

\[
d\theta^n \wedge \theta = i^n n! \det(h_{jk}) \theta^1 \wedge \cdots \wedge \theta^1 \wedge \theta
\]

\[
= n! \det(h_{jk})\eta^1 \wedge \eta^{n+1} \wedge \cdots \wedge \eta^2 \wedge \eta^0
\]

\[
= (-1)^nn! \det(h_{jk})\eta^0 \wedge \eta^1 \wedge \cdots \wedge \eta^{2n}.
\]

On the other hand, by its very definition \( \psi_a \) is the unique affine change of variable such that \( \psi_a(a) = 0 \) and \( (\psi_a \ast X_j)(0) = \partial_{x^j} \). Therefore, if we set \( X_j = X^k_j \partial_k \) and \( \eta^j = \eta^j_k dx^k \), then we can check that \( \psi_a(x)^j = \eta^j_k(x^k - a^k) \). Incidentally, we see that \( |\psi'_x| dx = |\det(\eta^j_k)dx^0 \wedge \cdots \wedge dx^{2n}| = |\eta^0 \wedge \cdots \wedge \eta^{2n}| \). Combining this with (7.73) then shows that

\[
|\psi'_x| dx = \frac{(-1)^n}{n! \det(h_{jk})}|d\theta^n \wedge \theta|.
\]

Now, it follows from (7.71), (7.72) and (7.74) that, in any local coordinates equipped with a frame \( Z_1, \ldots, Z_n \) of \( T_{1,0} \), the function \( \mathcal{I}_{P_0}(x) \) is equal to

\[
\sum_{p \in \mathcal{P}} \frac{1}{n!} p(X_0, Z, \bar{Z})(x) \det^{-1}(h_{jk}(x)) A_p(h(x), X_0(x), Z(x), \mu(x)).
\]

Together with (7.68), this shows that \( \mathcal{I}_{P_0}(x) \) is a local pseudohermitian invariant of weight \( n + 1 + w \).
Finally, suppose that \( P_\theta \) is admissible and its principal symbol is invertible in the Heisenberg calculus sense. For each pseudohermitian manifold \((M^{2n+1}, \theta)\) let \( Q_\theta \) be a parametrix for \( P_\theta \) in \( \Psi_H^{-m}(M) \). By definition the Green kernel logarithmic singularity \( \gamma_{P_\theta}(x) \) is equal to \( c_{Q_\theta}(x) \), and we know from Proposition \( \ref{log-reg} \) that \( Q_\theta \) is a pseudohermitian invariant \( \Psi_H \)DO of order \(-m\) and weight \(-w\). Therefore, it follows from the first part that \( \gamma_{P_\theta}(x) = J_{P_\theta}(x)|d\theta^m \wedge \theta| \), where \( J_{P_\theta}(x) \) is a local pseudohermitian invariant of weight \( n+1-w \). The proof is thus achieved. \( \Box \)

8. Logarithmic singularities of CR invariants \( \Psi_H \)DOs

In this section we shall make use of the program of Fefferman in CR geometry to give a geometric description of the logarithmic singularities of CR invariant \( \Psi_H \)DOs.

8.1. Local CR invariants and Fefferman’s program. The local CR invariants can be defined as follows.

**Definition 8.1.** A local scalar CR invariant of weight \( w \) is a local scalar pseudohermitian invariant \( I_\theta(x) \) such that

\[
I_{e^{f(x)}}(x) = e^{-wf(x)}I_\theta(x) \quad \forall f \in C^\infty(M, \mathbb{R}).
\]

When \( M \) is a real hypersurface the above definition of a local CR invariant agrees with the definition in \([Fe2]\) in terms of Chern-Moser invariants (with our convention about weight a local CR invariant that has weight \( w \) in the sense of \( \ref{eq:convention} \) has weight \( 2w \) in \([Fe2]\)).

The analogue of the Weyl curvature in CR geometry is the Chern-Moser tensor \((\text{CM}, \text{We})\). Its components with respect to any local frame \( Z_1, \ldots, Z_n \) of \( T_{1,0} \) are

\[
S_{jklm} = R_{jklm} - (P_{jk} h_{lm} + P_{kl} h_{jm} + P_{lm} h_{jk} + P_{jm} h_{lk}),
\]

where \( P_{jk} = \frac{1}{2} \kappa \sigma_{jk} - \frac{\kappa}{2(2n+1)} h_{jk} \) is the CR Schouten tensor. The Chern-Moser tensor is CR invariant of weight 1, so we get scalar local CR invariants by taking complete tensorial contractions. For instance, as scalar invariant of weight 2 we have

\[
|S|^2 = S^{jklm} S_{jklm},
\]

and as scalar invariants of weight 3 we get

\[
S_{ij} S_{kl} S_{pq} S_{i j} S_{p q} S_{j k l m} \quad \text{and} \quad S^{ik} S_{jp} S_{q k}.
\]

More generally, the Weyl CR invariants are obtained as follows. Let \( K \) be the canonical line bundle of \( M \), i.e., the annihilator of \( T_{1,0} \wedge \Lambda^n T^*_c M \) in \( \Lambda^{n+1} T^*_c M \). The Fefferman bundle is the total space of the circle bundle,

\[
\mathcal{F} := (K \setminus 0)/\mathbb{R}^*_+. 
\]

It carries a natural \( S^1 \)-invariant Lorentzian metric \( g_\theta \) whose conformal class depends only the CR structure of \( M \), for we have \( g_{e^{t\theta}} = e^{t} g_\theta \) for any \( f \in C^\infty(M, \mathbb{R}) \) (see \([Fe1], [Le] \)). Notice also that the Levi metric defines a Hermitian metric \( h^\theta_\sigma \) on \( K \), so we have a natural natural isomorphism of circle bundles \( \iota_\theta : \mathcal{F} \rightarrow \Sigma_\theta \), where \( \Sigma_\theta \subset K \) denotes the unit sphere bundle of \( K \).

**Lemma 8.2 (\([Fe2]\)).** Any local scalar conformal invariant \( I_\theta(x) \) of weight \( w \) uniquely defines a local scalar CR invariant of weight \( w \).
Proof. As $g_\theta$ is $S^1$-invariant the function $I_{g_\theta}(x)$ is $S^1$-invariant as well. Thus, if $\zeta$ is a local section of $\mathcal{F}$ then we have

$$ I_{g_\theta}(\zeta(x)) = I_{g_\theta}(e^{i\omega}\zeta(x)) \quad \forall \omega \in \mathbb{R}. $$

This means that the value of $I_{g_\theta}(\zeta(x))$ at $x$ does not depend on the choice of the local section $\zeta$ near $x$. Therefore, we define a smooth function $I_\theta(x)$ on $M$ by letting

$$ I_\theta(x) := I_{g_\theta}(\zeta(x)) \quad \forall x \in M, $$

where $\zeta$ is any given local section of $\mathcal{F}$ defined near $x$.

The fact that $I_\theta(x)$ is a local pseudohermitian invariant can be seen as follows. Let $Z_1, \ldots, Z_n$ be a local frame of $T_{1,0}$ near a point $a \in M$ and let $\{\theta, \theta^i, \theta^j\}$ be the dual coframe of the frame $\{X_0, Z_j, Z_j\}$. By standard multilinear algebra $\zeta_\theta = \det h_{\bar{j}k}\theta^{\bar{j}} \land \theta^1 \land \ldots \land \theta^n$ is a local section of $\Sigma_\theta$. Therefore, it defines a local fiber coordinate $\gamma \in \mathcal{F}$ such that $i_\theta = e^{i\gamma}\zeta$. Then by [Le, Thm. 5.1] the Fefferman metric is given by

$$ g_\theta = h_{\bar{j}k}\theta^{\bar{j}}\theta^k + 2\theta\sigma, \quad \sigma = \frac{1}{n+2}(d\gamma + i\omega_j - \frac{i}{2}h_{\bar{j}k}dh_{\bar{j}k} - \frac{1}{2(n+1)}\kappa_\theta). $$

Therefore, if $x_0, x_1, \ldots, x_{2n}$ are local coordinates for $M$ near $a$, then one can check that the components in the local coordinates $x_0, x_1, \ldots, x_{2n}, \gamma$ of the Fefferman metric $g_\theta$ and of its inverse are universal expressions of the form (7.15). It then follows that $I_{g_\theta}(\zeta_\theta(x))$ is a universal expression of the form (7.15) as well, so $I_\theta(x)$ is a local pseudohermitian invariant.

Finally, let $f \in C^\infty(M, \mathbb{R})$. As $I_\theta(x)$ is a conformal invariant of weight $w$, we have

$$ I_{g_{e^{\tau f}}} = I_{e^{\tau f}g_\theta}(\zeta(x)) = e^{-w|f(x)}I_{g_\theta}(\zeta(x)). $$

Hence $I_{e^{\tau f}}(x) = e^{-w|f(x)}I_{g_\theta}(\zeta(x))$. This completes the proof that $I_\theta(x)$ is a local CR invariant of weight $w$. \qed

Now, the Weyl CR invariant are the local CR invariants that are obtained from the Weyl conformal invariants by the process described in the proof of Lemma 8.2. Notice that for the Fefferman bundle the ambient metric was constructed by Fefferman [Fe2] as a Kähler-Lorentz metric. Therefore, the Weyl CR invariants are the local CR invariants that arise from complete tensorial contractions of covariant derivatives of the curvature tensor of Fefferman’s ambient Kähler-Lorentz metric.

Bearing this in mind the CR analogue of Proposition 4.1 is:

**Proposition 8.3** ([Fe2, Thm. 2], [BEG, Thm. 10.1]). Every local CR invariant of weight $\leq n + 1$ is a linear combination of local Weyl CR invariants.

In particular, we recover the fact that there is no local CR invariant of weight 1. Furthermore, we see that every local CR invariant of weight 2 is a constant multiple of $|S_\theta|$. Similarly, the local CR invariants of weight 3 are linear combinations of the invariants $\Phi_\theta$ and of the invariant $\Phi_\theta^\epsilon$ that arises from the Fefferman-Graham invariant $\Phi_\theta$ of the Fefferman Lorentzian space $\mathcal{F}$.  

*38*
8.2. Logarithmic singularities of CR invariant $\Psi_H$DOs. The CR invariant $\Psi_H$DOs are defined as follows.

**Definition 8.4.** A CR invariant $\Psi_H$DO of order $m$ and biweight $(w, w')$ is a pseudohermitian invariant $\Psi_H$DO $P_{\theta}$ such that

$$P_{e^{i\theta}} = e^{w'f} P_{\theta} e^{-w f} \quad \forall f \in C^\infty(M, \mathbb{R}).$$

(8.10)

We actually have plenty of CR invariant operators thanks to:

**Proposition 8.5 (JL1, CG).** Any conformally invariant Riemannian differential operator $L_{\theta}$ of weight $w$ uniquely defines a CR invariant differential operator $L_{\theta}$ of same weight.

*Proof.* Since the Fefferman metric is $S^1$-invariant, the circle $S^1$ acts by isometries on $\mathcal{F}$. Therefore, the operator $L_{g_{\theta}}$ is $S^1$-invariant, i.e., for any $\omega \in \mathbb{R}$ we have

$$L_{g_{\theta}}(v \circ e^{i\omega}) = (L_{g_{\theta}}v) \circ e^{i\omega} \quad \forall v \in C^\infty(\mathcal{F}).$$

(8.11)

Let $\pi : \mathcal{F} \to M$ be the canonical projection of $\mathcal{F}$ and let $u \in C^\infty(M)$. Then $\pi^* u$ is a $S^1$-invariant function on $\mathcal{F}$, so for any $x \in M$ and any $\zeta \in \pi^{-1}(x)$ we have

$$L_{g_{\theta}}(\pi^* u)(\zeta) = L_{g_{\theta}}(\pi^* u)(e^{i\omega} \zeta) \quad \forall \omega \in \mathbb{R}.$$ 

(8.12)

This means that $L_{g_{\theta}}(\pi^* u)(\zeta)$ does not depend on the choice of $\zeta$. Thus, we define a function $L_{\theta}(u)$ on $M$ by letting

$$L_{\theta}(u)(x) := L_{g_{\theta}}(\pi^* u)(\zeta), \quad \zeta \in \pi^{-1}(x).$$

(8.13)

Let us now consider local coordinates $x_0, \ldots, x_{2n}$ for $M$ equipped with the $H$-frame $X_0, \ldots, X_{2n}$ associated to a frame $Z_1, \ldots, Z_{2n}$ of $T_{1,0}$. Let $\theta^1, \ldots, \theta^n$ be the associated coframe of $\Lambda^{1,0}$, so that $\zeta := \det \frac{1}{2}(h_{j\bar{k}})\theta \wedge \theta^1 \ldots \theta^n$ is a local section of $\Sigma_{\theta}$. Let $\gamma$ be the corresponding local fiber coordinate of $\mathcal{F}$ in such way that $i_{\theta} = e^{i\gamma} \zeta$. Since $L_{\theta}$ is a Riemannian invariant differential operator there exist finitely many universal functions $a_{\alpha\beta\delta\kappa}(g)$ in $C^\infty(M_{2n+2}(\mathbb{R}^n)_+)$ such that, in the local coordinates $x_0, \ldots, x_{2n}, \gamma$ of $\mathcal{F}$, we have

$$L_{g_{\theta}} = \sum a_{\alpha\beta\delta\kappa}(g_{\theta}(x))(\partial^\alpha g_{\theta}(x))^\beta \partial^\delta \partial_{\gamma}.$$ 

(8.14)

Notice that $S^1$-invariance corresponds to translation-invariance with respect to the variable $\gamma$. This is reflected in the property that the components of $g_{\theta}$ don’t depend on $\gamma$. Furthermore, we see that for any smooth function $u(x)$ of the local coordinates $x_0, \ldots, x_{2n}$ we have

$$L_{\theta}(u)(x) = \sum a_{\alpha\beta\delta\kappa}(g_{\theta}(x))(\partial^\alpha g_{\theta}(x))^\beta \partial^\delta u(x).$$

(8.15)

In particular, this shows that $L_{\theta}$ is a differential operator.

As explained in the proof of Lemma 8.2, the components of $g_{\theta}(x)$ in the local coordinates $x_0, \ldots, x_{2n}, \gamma$, as well as their derivatives, are universal expressions of the form (7.15). Therefore, from (8.15) we deduce that there exists a finite family $(p_{k\delta\rho}) \subset C^\infty(\Omega)$ such that, in any local coordinates equipped with the $H$-frame associated to a frame $Z_1, \ldots, Z_{2n}$ of $T_{1,0}$, the differential operator $L_{\theta}$ is equal to

$$\sum_{k,\delta,\rho} p(X_0, \overline{Z})(x) b_{k\delta,\rho}(h(x), X_0(x), Z(x))(-iX_0)^k(-iZ)^\delta(-i\overline{Z})^\rho.$$ 

(8.16)

It then follows that $L_{\theta}$ is a pseudohermitian invariant differential operator.
Finally, let $f \in C^\infty(M, \mathbb{R})$. Since $L_\theta$ is conformally invariant of biweight $(w, w')$ we have $L_{g_\theta f} = e^{w f} L_{g_\theta} e^{-w f}$. Hence $L_{e^{w f} \theta} = e^{w f} L_{g_\theta} e^{-w f}$. This completes the proof that $L_\theta$ is a CR invariant differential operator of biweight $(w, w')$. □

When $L_\theta$ is the Yamabe operator the corresponding CR invariant operator is the CR Yamabe operator introduced by Jerison-Lee [JL1] in their solution of the Yamabe problem on CR manifold. It can be defined as follows.

First, the analogue of the Laplacian is provided by the horizontal sublaplacian $\Delta_b : C^\infty(M) \to C^\infty(M)$ defined by the formula,

$$\Delta_b = d^* b d b, \quad d_b = \pi \circ d,$$

where $\pi \in C^\infty(M, \text{End} T^* M)$ is the orthogonal projection onto $H^*$. In fact, if $Z_1, \ldots, Z_n$ is a local frame of $T_{1,0}$ then by [Le, Prop. 4.10] we have

$$\Delta_b = \nabla Z_j \nabla Z_j + \nabla Z_j \nabla Z_j.$$

It follows from this formula that $\Delta_b$ is a sublaplacian in the sense of [BGr] and its principal symbol in the Heisenberg calculus sense is invertible (see [BGr], [Po2]).

The CR Yamabe operator is given by the formula,

$$\Box_\theta = \Delta_b + \frac{n}{n+2} \kappa_\theta,$$

where $\kappa_\theta$ is the Tanaka-Webster scalar curvature. This is a CR invariant differential operator of biweight $(\frac{-n}{2}, -\frac{n+2}{2})$. Moreover, as $\Box_\theta$ and $\Delta_b$ have same principal symbol, we see that the principal symbol of $\Box_\theta$ is invertible in the Heisenberg calculus sense.

Next, Gover-Graham [GG] proved that for $k = 1, \ldots, n+1$ the GJMS operator $\Box_\theta^{(k)}$ on the Fefferman bundle gives rise to a selfadjoint differential operator,

$$\Box_\theta^{(k)} : C^\infty(M) \to C^\infty(M).$$

This is a CR invariant operator of biweight $(\frac{k-(n+1)}{2}, -\frac{k+n+1}{2})$ and it has same principal symbol as

$$\Box_\theta^{(k)} = (\Delta_b + i(k-1) X_0)(\Delta_b + i(k-3) X_0) \cdots (\Delta_b - i(k-1) X_0).$$

In particular, unless for the critical value $k = n+1$, the principal symbol of $\Box_\theta^{(k)}$ is invertible in the Heisenberg calculus sense (see [Po2 Prop. 3.5.7]). The operator $\Box_\theta^{(k)}$ is called the CR GJMS operator of order $k$. For $k = 1$ we recover the CR Yamabe operator. Notice that by making use of a CR tractor calculus we also can define CR GJMS operators of order $k \geq n + 2$ (see [GG]).

More generally, the conformally invariant Riemannian differential operators of Alexakis [A12] and Juhl [Ju] give rise to CR invariant differential operators. If we call Weyl CR invariant differential operators the operators induced by the Weyl operators of [A12], then a natural question would be to determine to which extent these operators allows us to exhaust all the CR invariant differential operators.

We are now ready to prove the main result of this section.

**Theorem 8.6.** Let $P_\theta$ be a CR invariant $\Psi_H DO$ of order $m$ and biweight $(w, w')$.

1) The logarithmic singularity $c_{P_\theta}(x)$ takes the form

$$c_{P_\theta}(x) = \mathcal{I}_{P_\theta}(x) d\theta^n \wedge \theta,$$
where $I_\theta(x)$ is a scalar local CR invariant of weight $n + 1 + w - w'$. If we further have $w < w'$, then $I_\theta(x)$ is a linear combination of Weyl CR invariants of weight $n + 1 + w - w'$.

2) Assume that $P_\theta$ is admissible and its principal symbol is invertible in the Heisenberg calculus sense. Then the Green kernel logarithmic singularity of $P_\theta$ takes the form

\[ \gamma_{P_\theta}(x) = J_{P_\theta}(x)|d\theta^n \wedge \theta|, \]

where $J_{P_\theta}(x)$ is a scalar local CR invariant of weight $n + 1 + w + w'$. If we further have $w \geq w'$, then $J_{P_\theta}(x)$ is a linear combination of Weyl CR invariants of weight $n + 1 - w + w'$.

**Proof.** Since $P_\theta$ is a pseudohermitian invariant $\Psi_H$DO of weight $w - w'$, by Proposition \[\ref{prop:invariants1}\] the logarithmic singularity $c_{P_\theta}(x)$ is of the form $c_{P_\theta}(x) = I_{P_\theta}(x)$, where $I_{P_\theta}(x)$ is a local pseudohermitian invariant of weight $w - w'$.

Let $f \in C^\infty(M, \mathbb{R})$. As $P_\theta$ is conformally invariant of biweight $(w, w')$, by Proposition \[\ref{prop:admissible1}\] we have $c_{P_\theta f}(x) = e^{-(w-w')}f(x)c_{P_\theta}(x)$. Since $d(e^f \theta)^n \wedge (e^f \theta) = e^{(n+1)f}d\theta^n \wedge \theta$ it follows that $I_{P_\theta f}(x) = e^{-(n+1+w-w')}f(x)I_{P_\theta}(x)$. Thus $I_\theta$ is a local CR invariant of weight $n + 1 + w - w'$. If we further have $w \leq w'$ then the weight of $I_\theta(x)$ is $\leq n + 1$, so we may apply Proposition \[\ref{prop:invariants1}\] to deduce that $I_\theta(x)$ is a linear combination of Weyl CR invariants of weight $n + 1 + w - w'$.

Now, suppose that $P_\theta$ is admissible and its principal symbol is invertible in the Heisenberg calculus sense. Then by using Proposition \[\ref{prop:admissible1}\] and Proposition \[\ref{prop:invariants1}\] and by arguing as above, we can show that $\gamma_{P_\theta}(x) = J_{P_\theta}(x)|d\theta^n \wedge \theta|$, where $J_{P_\theta}(x)$ is a local CR invariant of weight $n + 1 - w + w'$. If we further have $w \geq w'$, then by Proposition \[\ref{prop:invariants1}\] the invariant $J_{P_\theta}(x)$ is actually a linear combination of Weyl CR invariants of weight $n + 1 - w + w'$.

Finally, we can make use of Theorem \[\ref{thm:invariants1}\] to derive the following invariant expression of the Green kernel logarithmic singularities of the CR GJMS operators.

**Theorem 8.7.** For $k = 1, \ldots, n$ we have

\[ \gamma_{\Box_\theta^{(k)}}(x) = c^{(k)}_{\theta}(x)|d\theta^n \wedge \theta|, \]

where $c^{(k)}_{\theta}(x)$ is a linear combination of scalar Weyl CR invariants of weight $n + 1 - k$.

In particular, we have

\[ c^{(n)}_{\theta}(x) = 0, \quad c^{(n-1)}_{\theta}(x) = \alpha_n|S|^2, \]

\[ c^{(n-2)}_{\theta}(x) = \beta_n S^k_{ij} \partial_i \partial_j S_{kl} \partial^p \partial^q S^{ij}_{pq} + \gamma_n S^k_{ij} \partial_i \partial^q S^{ij}_{pq} S^l_{kl} \partial^q \partial^q + \delta_n \Phi_\theta, \]

where $S$ is the Chern-Moser curvature tensor, $\Phi_\theta$ is the CR Fefferman-Graham invariant, and the constants $\alpha_n, \beta_n, \gamma_n$ and $\delta_n$ depend only on $n$.

**Proof.** We already know that the CR GJMS operator $\Box_\theta^{(k)}$ is a CR invariant differential operator of biweight $\left(\frac{k-(n+1)}{2}, -\frac{k+n+1}{2}\right)$ and for $k = 1, \ldots, n$ its principal symbol is invertible in the Heisenberg calculus sense. Therefore, in order to be able to apply Theorem \[\ref{thm:invariants1}\] it remains to show that $\Box_\theta^{(k)}$ is admissible. By \[\ref{prop:admissible1}\] the principal symbol of $\Box_\theta^{(k)}$ agrees with that of $(\Delta_b + i(k-1)X_0) \cdots (\Delta_b - i(k-1)X_0)$. Therefore, in view of Proposition \[\ref{prop:admissible1}\] in order to prove that $\Box_\theta^{(k)}$ is admissible it is enough to show that so is any operator of the form $\Delta_b - i\mu X_0$, $\mu \in \mathbb{C}$.
Consider local coordinates equipped with a $H$-frame $X_0, \ldots, X_{2n}$ associated to a frame $Z_1, \ldots, Z_n$ of $T_{1,0}$, so that we have $Z_j = X_j - i X_{n+j}$. It follows from (8.18) that $\Delta_b$ as same principal part as $-h^{jk} Z_k Z_j - h^{jk} Z_k Z_{n+j}$, so the principal symbol of $\Delta_b - i \mu X_0$ is equal to

\[
(8.27) \quad -h^{jk}(x) (\xi_k + i \xi_{n+k})(\dot{\xi}_j - i \dot{\xi}_{n+j}) - h^{jk}(x) (\xi_k - i \xi_{n+k})(\dot{\xi}_j - i \dot{\xi}_{n+j}) + \xi_0.
\]

This shows that $\Delta_b - i \mu X_0$ is admissible.

Now, we may apply Theorem 8.6 to deduce that for $k = 1, \ldots, n$ the Green kernel logarithmic singularity of $\Box_{\theta}^{(k)}$ is of the form $\gamma_{\Box_{\theta}^{(k)}}(x) = c_{\theta}^{(k)}(x) d\theta^n \wedge \theta(x)$, where $c_{\theta}^{(k)}(x)$ is a linear combination of Weyl CR invariants of weight $n + 1 - k$. The formulas (8.25)–(8.26) then follow from the facts that there is no nonzero scalar Weyl CR invariant of weight 1, that the only scalar Weyl CR invariants of weight 2 is $|S|^2_\theta$, and that the only scalar Weyl CR invariants of weight 3 are the invariants (8.4) and the CR Fefferman-Graham invariant $\Phi_\theta$.
