93. Home Environmental Contamination Is Associated with Community-associated Methicillin-resistant Staphylococcus aureus Infection in Treated Patients

Meghan Davis, PhD, DVM, MPH; Daniel Morris, DVM, MPH, DACVD; Valerie Cluzet, MD; Warren Bilker, PhD; Pam Tolomeo, MPH; Kathleen G. Julian, MD; Patrick Baron, PhD MPH; Amy Brazil, VMD MPH; Jacqueline Ferguson, MHS; Sally Ann Iverson, DVM, MPH; Jonathan Sabahzaban, BS, MPH; Shanna Ludwig, PhD; Raofeng Hu, MD; Shelley Rankin, PhD; Irving Nachamin, DrPH, MPH, FIDSA; Ebbing Lautenbach, MD, MPH, MSCIE; CDC Prevention Epidemiants Network; Environmental Health and Engineering, Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland; University of Pennsylvania School of Veterinary Medicine, Philadelphia, Pennsylvania; Infectious Diseases, Hospital of University of Pennsylvania, Philadelphia, Pennsylvania; *Center for Clinical Epidemiology and Biostatistics, University of Pennsylvania Perelman School of Medicine, Philadelphia, Pennsylvania; Penn State Hershey Medical Center, Hershey, Pennsylvania; Davidson College, Davidson, North Carolina; Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland; University of Pennsylvania School of Medicine, Philadelphia, Pennsylvania; *Biotechnology, University of Pennsylvania School of Veterinary Medicine, Philadelphia, Pennsylvania; Department of Pathology and Laboratory Medicine, University of Pennsylvania, Perelman School of Medicine, Philadelphia, Pennsylvania; *Division of Infectious Diseases, Hospital of University of Pennsylvania, Philadelphia, Pennsylvania

Session: 30. It’s not just Bones: Skin and Bones

Background. Strategies to interrupt household transmission of community-associated methicillin-resistant *Staphylococcus aureus* (CA-MRSA) target human colonization to show mixed results. Our aim was to determine whether home environmental contamination and pet carriage with MRSA were associated with re-colonization or persistent colonization of index patients diagnosed with CA-MRSA skin or soft-tissue infection (STTI).

Methods. Index patients from a randomized controlled trial (NCT00966446) that tested the impact of decolonization of people eligible to participate in this study. Before randomization, eight environmental sites and all pets were sampled in the home. Patients were treated by their physician for the initial STTI between diagnosis (visit 0) and the home visit (visit 1). They provided swabs every 2 weeks for 3 months (7 visits). After broth-enrichment culture, MRSA isolates were PCR-confirmed and spa-typed.

Results. Of 88 index patients recruited from the main trial, 64 (73%) provided swabs for 23 visits and were included in this analysis. At visit 1, 41 (64%) house-holds were MRSA contaminated and 6 (9%) had MRSA-positive pets. All MRSA-positive pets lived in homes with MRSA environmental contamination. After visit 1, 42 (66%) index patients and their household members were block-randomized to nasal mupirocin and chlorhexidine body wash decolonization. Thirty-seven (58%) of patients had two consecutive nasal swabs (de-colonization failure) (15%) of these later were MRSA-positive (re-colonized). Patients with home contamination had higher rates of re-colonization than those without (Cox proportional hazard ratio 6.05 [95% CI: 1.2, 30.6], P < 0.03). Persistent colonization (all or but one swab positive) was identified in 6 (9%) of index patients and was associated with identification of matching spa-types in environmental and subsequent human MRSA isolates (P < 0.05).

Conclusion. In patients with MRSA STTI, MRSA-contaminated homes, and potentially MRSA-positive pets, are associated with re-colonization and persistent colonization. Future studies are needed to determine whether environmental decontamination can improve the success of household decolonization interventions.

124. Current Epidemiology of Serogroup W Meningococcal Disease—United States, 2010–2015

Heidi Soeters, PhD, MPH; Amy Blain, MPH; How-Yi Chang, PhD; Melissa Whaley, MS, MPH; Jessica Meacneil, MPH; National Center for Immunization and Respiratory Diseases, Centers for Disease Control and Prevention, Atlanta, Georgia

Session: 40. Adult Central Nervous System Infection

Background. Serogroup W (NmW) meningococcal disease is a rare but severe infection. Following an NmW outbreak after the Hajj in 2000, NmW disease, predominately caused by sequence type (ST)-11 clonal complex (cc), rapidly increased in South Africa, South America, and the UK. We describe NmW meningococcal disease epidemiology in the USA during 2010–2015.

Methods. Data were collected from the Notifiable Diseases Surveillance System, Active Bacterial Core surveillance, and state health departments. Isolates were serogrouped via slide agglutination and real-time polymerase chain reaction. For cases lacking a serogroup result at CDC, the state result was used. Case-fatality ratios (CFR) were calculated using the proportion of cases with known outcomes as the denominator. cc and ST were determined using multilocus sequence typing (MLST).

Results. From 2010 to 2015, 3,504 meningococcal disease cases were reported to CDC; 2,976 (85%) had a serogroup result, of which 290 (10%) were NmW. Although the number of NmW cases reported annually remained fairly stable (range: 40–57), the total number of reported meningococcal disease cases decreased by 60%, and the proportion of cases due to NmW increased from 6% (42/830) in 2010 to 12% (40/332) in 2015. The majority of NmW cases were reported from five states: Florida (n = 106), California (n = 31), New York (n = 25), Georgia (n = 19), and Oregon (n = 11). Half of people with NmW disease were male, 185 (64%) were white, and 84 (29%) were Hispanic. The median age was 51 years (interquartile range: 26–70). Overall, 20% (52/259) of NmW cases were fatal, compared with CFRs for serogroups B (15%), Y (18%), or C (24%). NmW CFR was highest among adults aged 50–59 years (38%). MLST results were available for 119 (41%) of NmW cases: 76 (64%) were cc11, 40 (34%) were cc22, and 1 each were cc23, cc32, and an unassigned cc. cc appeared to be geographically associated: cc11 was concentrated in Florida and Georgia, while cc22 predominated on the West coast. Within cc11, the majority of isolates (86%) were ST-11, and within cc22 the majority (73%) were ST-22.

Conclusion. A rapid increase in NmW disease has not been observed in the USA. Most NmW cases were reported in a limited number of states, with geographic differences in clonal complex.

125. Increased Risk of Invasive Meningococcal Disease Associated with Primary and Secondary Immunodeficiency

Lene Foug Lundbo, MD, PhD; Zinta Barrella Harboe, MD; Lars Smith Hansen, BS; Kjell Andersson, Thomas Bennfeldt, MD, DVM;仿佛; Department of Infectious Diseases, Hvidovre University Hospital, University of Copenhagen, Hvidovre, Denmark; Department of Infectious Diseases, Rigshospitalet, Copenhagen University Hospital, Copenhagen Ø, Denmark; Clinical Research Centre, Hvidovre Hospital, University of Copenhagen, Hvidovre, Denmark; Department of Infectious Disease, Hvidovre University Hospital, Hvidovre, Denmark

Session: 40. Adult Central Nervous System Infection

Background. Risk of invasive meningococcal disease (IMD) is increased for persistent complement deficiency and HIV infection. However, risk associated with other primary and secondary immunodeficiency is unknown.

Methods. Nationwide case-control study of adults aged >18 years. Cases and matched controls were identified by registry linkage. Primary and secondary immunodeficiencies diagnosed prior to IMD were based on International Classification of Disease (ICD), eight or tenth revision. Odds ratios (OR) with 95% confidence intervals (CI) were estimated by conditional logistic regression after adjustment for sex, age, and the year of IMD.

Results. We identified 2,179 IMD cases (46% male) with a median age of 44 years (interquartile range: 24–63 years). Increased risk of IMD was associated with HIV infection (OR 10.03 [95% confidence interval (CI), 2.91–34.66]), splenectomy/splenic resection (OR 6.88 [95% CI, 3.9–14.82]), solid organ transplantation (SOT) (OR 20.00 [95% CI, 5.00–79.96]), hemolytic anemia (OR 7.78 [95% CI, 2.90–20.90]), antibody deficiency (OR 6.67 [1.11–39.90]) and autoimmune diseases (OR 1.80 [95% CI, 1.4–21.14]). Primary immunodeficiency overall was not associated with an increased risk (OR 0.95 [95% CI, 0.61–1.36]).

Conclusion. This large study of Danish adults with IMD over four decades showed an increased risk of IMD associated with HIV infection, SOT, asplenia, hemolytic anemia, antibody deficiency, and autoimmune disease ranging from 2- to 20-fold increased risk. Vaccination may be warranted in these populations.

Disclosures. Z. Barrella Harboe, Pfizer: independent physician, Travel grants.

126. Use of Adjunctive Steroids and Incidence of Delayed Cerebral Venous Thrombosis in Adults with Bacterial Meningitis

Cynthia Gallegos, MD; Lucrècia Salazar, MD; Farrell Tobolowsky, DO; Masayuki Nigo, MD; Rodrigo Hashun, MD, MPH; Infectious Disease, University of Texas Medical School at Houston, Houston, Texas; Division of Infectious Diseases, University of Texas McGovern Medical School at Houston, Houston, Texas; Internal Medicine, University of Texas Medical School at Houston, Houston, Texas; Division of Infectious Disease, Department of Internal Medicine, University of Texas Health Science Center at Houston, McGovern Medical School, Houston, Texas; Division of Infectious Diseases, University of Texas Health Science Center at Houston, McGovern Medical School, Houston, Texas

Session: 40. Adult Central Nervous System Infection

Background. Bacterial meningitis is associated with significant morbidity and mortality. Adjunctive steroids decrease mortality in adults with meningitis due to *Streptococcus pneumoniae*but its use has been recently linked to the development of delayed cerebral thrombosis (DCT). The purpose of our study was to determine the utilization of adjunctive steroids and its incidence.
Methods. A retrospective multicenter study involving 10 Houston area hospitals from 2008 to 2016. Data was gathered from 120 adults with culture proven community-acquired bacterial meningitis. An adverse clinical outcome was defined as a Glasgow outcome score of 1–4.

Results. There was a total of 120 patients enrolled; of which, 55% were male. Adjunctive intravenous steroids were administered in 82 (68%) patients with bacterial meningitis. The steroid median duration was 3.8 days. The average age of patients was 55.3 years (range 20–92). There was no difference in Charlson comorbidity score, immunosuppression, presence of sinustitis or otitis, fever, meningeval signs or symptoms, abnormal neurological findings. Gram stain or severity of illness, based on ACRON score (P > 0.05), between patients who received steroids and those that did not. Older patients, age >65, were less likely to receive adjunctive steroids (P = 0.028). The most common organism isolated was Streptococcus pneumoniae, which occurred in 46 (38%) patients. An adverse clinical outcome was seen in 46 (38%) patients with no difference between groups (P = 0.819). Delayed cerebrospinal fluid was seen in a total of 7 (5.7%) patients with bacterial meningitis. Of those, 1 patient (2.6%) did not receive steroids and the remaining 8 (10.9%) patients received steroids (P = 0.158). Five cases of meningitis that were complicated by DCT were caused by Streptococcus pneumoniae, 1 by Listeria monocytogenes, and 2 with Staphylococcus aureus.

Conclusion. Adjunctive steroids are being used in the majority of adults with bacterial meningitis but it is not uniformly associated with DCT, a devastating complication.
