SYMmetry for a General Class of Overdetermined Elliptic Problems

F. Brock

Abstract. Let Ω be a bounded domain in \( \mathbb{R}^N \), and let \( u \in C^1(\Omega) \) be a weak solution of the following overdetermined BVP:

\[
-\nabla (g(|\nabla u|)|\nabla u|^{-1} \nabla u) = f(|x|, u), \quad u > 0 \text{ in } \Omega \quad \text{and} \quad u(x) = 0, \quad |\nabla u(x)| = \lambda(|x|) \text{ on } \partial \Omega,
\]

where \( g \in C([0, +\infty)) \cap C^1((0, +\infty)) \) with \( g(0) = 0, \quad g'(t) > 0 \text{ for } t > 0, \quad f \in C([0, +\infty) \times [0, +\infty)), \quad f \text{ is nonincreasing in } |x|, \quad \lambda \in C([0, +\infty)) \text{ and } \lambda \text{ is positive and nondecreasing.} \)

We show that \( \Omega \) is a ball and \( u \) satisfies some "local" kind of symmetry. The proof is based on the method of continuous Steiner symmetrization.

Key words: degenerate elliptic equation, overdetermined boundary value problem, symmetry of the solution, continuous rearrangement

2000 Mathematics Subject Classification: 28D10, 35B05, 35B50, 35J25, 35J60, 35J65

1. Introduction

In a celebrated paper [34] Serrin proved the following symmetry result for an overdetermined elliptic boundary value problem:

**Theorem A.** Let \( \Omega \subset \mathbb{R}^N \) be a bounded domain with \( C^2 \)-boundary, and let \( u \in C^2(\overline{\Omega}) \) satisfy

\[
Lu \equiv a(u, |\nabla u|)\Delta u + \sum_{i,j=1}^{N} b(u, |\nabla u|)u_{x_i}u_{x_j} = c(u, |\nabla u|),
\]

(1.1) \( \quad u > 0 \text{ in } \Omega, \)

(1.2) \( \quad u = 0, \quad |\nabla u| = \text{constant on } \partial \Omega, \)

where \( a, b \) and \( c \) are continuously differentiable in each variable and \( L \) is uniformly elliptic. Then \( \Omega \) is a ball and \( u \) is radially symmetric about the center of the ball.

The proof of Theorem A in [34] uses the so-called moving plane method which became very popular thanks to Gidas, Ni and Nirenberg’s paper [17]. The method combines symmetry arguments and boundary versions of the strong maximum principle, and it has often been applied to show the symmetry of solutions in overdetermined problems, e.g. in [11], [11], [12], [24], [28], [31]-[33], [36], [38]. The moving plane device applies to very general - even

\[ ^{1}F. \text{ Brock: University of Rostock, Department of Mathematics, Ulmenstr. 69, 18057 Rostock, Germany, email: friedemann.brock@uni-rostock.de} \]
fully nonlinear - elliptic equations. On the other hand, if the equation degenerates and/or contains terms which are less regular, then the method often fails.

Several other tools have been applied in such situations. Let us give a short overview. One approach is based on a comparison principle which is combined with some Rellich-type identity, see e.g. [37], [16], [26], [30], [15] and [13]. Another idea, used e.g. in [4], [27], is to exploit some integral identity which is equivalent to the overdetermined problem. Although these two methods can be applied to degenerate operators - for instance, to the $p$-Lapacian - they are useful only for very special equations. A third method is based on a comparison with suitable radial solutions of the equation, and it is applicable to situations when the solution of the boundary value problem is unique, see e.g. [21], [18] and [19]. A fourth approach is based on the method of domain derivative which has been widely investigated in shape optimization (see [35]). This device again seems useful in problems where the solution of the boundary value problem is unique (see [10], [20]). Note, this approach also highlights the relation between a second ('overdetermined') boundary condition and minimization of appropriate domain functionals, see [2], [3]. The method of domain derivative has also been combined with another tool: the so-called continuous Steiner symmetrization (CStS) (see [9], [8]). The idea of CStS is to find "local analogues" to some well-known rearrangement inequalities (see [29], [23], [5], [6]). The author exploited this method to prove symmetry results for nonnegative solutions of boundary value problems in symmetric domains (see [6], [7]).

The aim of this paper is to give a new approach to overdetermined problems which is based on the CStS, but does not use domain derivatives. Although our method is restricted to operators in divergence form, we allow nonsmooth terms in the equation, and the solution of the boundary value problem need not be unique.

We fix some notation. By $x = (x_1, \ldots, x_N)$ we denote a point in $\mathbb{R}^N$, and by $|x|$ its norm. Our main result is

**Theorem 1:** Let $f : [0, +\infty) \times [0, +\infty) \to \mathbb{R}$ be a bounded measurable function, such that the mapping $v \mapsto f(r, v)$ is continuous, uniformly for all $r$, and the mapping $r \mapsto f(r, v)$ is nonincreasing, $(r, v) \in [0, +\infty)$. Let $g \in C([0, +\infty)) \cap C^1((0, +\infty))$, with $g(0) = 0$, $g'(t) > 0$ for $t > 0$, and let $\lambda \in C([0, +\infty))$ be a positive and nondecreasing function. Further, let $\Omega$ be a bounded domain, and let $u \in C^1(\Omega) \cap C(\overline{\Omega})$ be a weak solution of the following problem,

\begin{align}
- \nabla \left( g(|\nabla u|) \frac{\nabla u}{|\nabla u|} \right) &= f(|x|, u), \ u > 0 \quad \text{in } \Omega, \\
\quad u(x) &= 0 \quad \text{on } \partial \Omega, \\
\quad \text{Given } \varepsilon > 0, \text{ there is an open set } U \text{ containing } \partial \Omega \text{ such that}
\end{align}

\begin{align}
||\nabla u(x)| - \lambda(|x|)| < \varepsilon \quad \forall x \in U \cap \Omega.
\end{align}
Then $\Omega$ and $u$ satisfy the following symmetry properties:

$\Omega$ is ball,

\begin{equation}
\Omega = \left( \bigcup_{k=1}^{m} C_k \right) \cup S,
\end{equation}

where

\begin{equation*}
C_k := \{ x \in \Omega : r_k < |x - y^k| < R_k \}, \quad R_k > r_k \geq 0, \ y^k \in \Omega,
\end{equation*}

\begin{equation*}
\frac{\partial u}{\partial \rho} < 0 \quad \text{in} \ C_k, \quad (\rho := |x - y^k|),
\end{equation*}

\begin{equation*}
u(x) \geq u(y) \quad \text{if} \ 0 \leq |x - y^k| \leq |y - y^k| = r_k, \quad 1 \leq k \leq m, \quad \text{and}
\n\begin{equation*}
\nabla u = 0 \quad \text{in} \ S.
\end{equation*}

The sets on the right-hand side of (1.6) are mutually disjoint and there can be a countable number of annuli $C_k$, i.e. $m = +\infty$.

**Remark 1:**

(a) (1.3) means

\begin{equation}
\int_{\Omega} g(|\nabla u|) \frac{\nabla u \cdot \nabla v}{|\nabla u|} \, dx = \int_{\Omega} f(|x|, u) v \, dx \quad \forall v \in W^{1,1}_0(\Omega) \cap W^{1,\infty}(\Omega),
\end{equation}

where the expression $g(|y|) \frac{v}{|y|}$, $(y \in \mathbb{R}^N)$, is interpreted as the zero vector, if $y = 0$.

Note that if $\partial \Omega$ is smooth and $u \in C^1(\Omega)$, then (1.5) means

\begin{equation}
\frac{\partial u}{\partial \nu}(x) = \lambda(|x|) \quad \text{on} \ \partial \Omega, \quad (\nu : \text{exterior unit normal}).
\end{equation}

(b) Theorem 1 falls out of the scope of the above mentioned results for the following reasons:
- We do not assume that $f$ is smooth in the second variable.
- The solution of the boundary value problem (1.3), (1.4) might be not unique.
- The differential operator in (1.3) is not assumed to be uniformly elliptic.

We also emphasize that the solution $u$ is not radially symmetric in general. For instance, there are examples of non-symmetric solutions of problem (1.3), (1.4) in a ball in the $p$-Laplacian case, that is if $g(z) = z^{p-1}$ for some $p > 1$ (see [6], [8]).

Now we outline the content of the article. In section 2, we give the definition of CStS and we present some results of [5]-[7] which will be of later use. In Section 3 we prove Theorem 1 and we give some extensions of the result in Theorem 2.

**2. Continuous Steiner symmetrization**

For points $x \in \mathbb{R}^N$, $(N \geq 2)$, we write $x = (x_1, x')$, where $x' = (x_2, \ldots, x_N)$, and for any set $M \subset \mathbb{R}^N$ let $\chi(M)$ the characteristic function of $M$. If $u : \mathbb{R}^N \to \mathbb{R}$, then let $\{u > a\}$ and $\{b \geq u > a\}$ denote the sets $\{x \in \mathbb{R}^N : u(x) > a\}$, and $\{x \in \mathbb{R}^N : b \geq u(x) > a\}$, respectively, $(a, b \in \mathbb{R}, a < b)$. Let $\mathcal{L}^k$ denote $k$-dimensional Lebesgue measure, $(1 \leq k \leq N)$.
and \( \| \cdot \|_p \) the usual norm in \( L^p(\mathbb{R}^N) \), \( 1 \leq p \leq +\infty \). By \( \mathcal{M}(\mathbb{R}^N) \) we denote the family of Lebesgue measurable - measurable in short - sets in \( \mathbb{R}^N \) with finite measure. Finally, let \( \mathcal{S}_+(\mathbb{R}^N) \) denote the class of real, nonnegative measurable functions \( u \) satisfying
\[
\mathcal{L}^N(\{u > c\}) < +\infty \quad \forall c > 0.
\]
Note that nonnegative functions in \( L^p(\mathbb{R}^N) \), \( 1 \leq p < +\infty \), belong to \( \mathcal{S}_+(\mathbb{R}^N) \). Generally we treat measurable sets and functions in a.e. sense.

Given a unit vector \( e \in \mathbb{R}^n \), a continuous Steiner symmetrization (CStS) is a continuous homotopy which connects sets \( M \in \mathcal{M}(\mathbb{R}^N) \) and functions \( u \in \mathcal{S}_+(\mathbb{R}^N) \) with their Steiner symmetrizations in direction \( e \), \( M^* \), respectively \( u^* \). Homotopies of such type can be constructed in different ways (see [5], [6] and the references cited therein). Below we define a variant of CStS which has been investigated by the author in [5], [6].

For the convenience of the reader we first recall the definition of the well-known Steiner symmetrization (see e.g. [22]).

**Definition 1:** (Steiner symmetrization)

(i) For any set \( M \in \mathcal{M}(\mathbb{R}) \) let
\[
M^* := \left( -\frac{1}{2} \mathcal{L}^1(M), \frac{1}{2} \mathcal{L}^1(M) \right)
\]
denote the (one-dimensional) symmetrization of \( M \).

(ii) Let \( M \in \mathcal{M}(\mathbb{R}^N), (N \geq 2) \). For every \( x' \in \mathbb{R}^{N-1} \) let
\[
M(x') := \{x_1 \in \mathbb{R} : (x_1, x') \in M \}.
\]
The set
\[
(2.1) \quad M^* := \{x = (x_1, x') : x_1 \in (M(x'))^*, x' \in \mathbb{R}^{N-1}\}
\]
is called the Steiner symmetrization of \( M \) (with respect to \( x_1 \)).

(Note that \( M^* \) is symmetric and convex with respect to the hyperplane \( \{x_1 = 0\} \).

(iii) If \( u \in \mathcal{S}_+(\mathbb{R}^N), (N \geq 2) \), then the function
\[
(2.2) \quad u^*(x) := \begin{cases} 
\sup \{c > 0 : x \in \{u > c\}^* \} & \text{if } x \in \bigcup_{c>0}\{u > c\}^* \\
0 & \text{if } x \notin \bigcup_{c>0}\{u > c\}^*, \quad x \in \mathbb{R}^N,
\end{cases}
\]
is called the Steiner symmetrization of \( u \) (with respect to \( x_1 \)).

(Note that \( u^*(x_1, x') \) is symmetric with respect to \( \{x_1 = 0\} \) and nonincreasing in \( x_1 \) for \( x_1 > 0 \).

**Definition 2:** (Continuous symmetrization of sets in \( \mathcal{M}(\mathbb{R}) \))

A family of set transformations
\[
E_t : \mathcal{M}(\mathbb{R}) \longrightarrow \mathcal{M}(\mathbb{R}), \quad 0 \leq t \leq +\infty,
\]
satisfying the properties, \((M, N \in \mathcal{M}(\mathbb{R}), \ 0 \leq s, t \leq +\infty)\)

(i) \(\mathcal{L}^1(E_t(M)) = \mathcal{L}^1(M)\), (equimeasurability),

(ii) if \(M \subset N\), then \(E_t(M) \subset E_t(N)\), (monotonicity),

(iii) \(E_t(E_s(M)) = E_{s+t}(M)\), (semigroup property),

(iv) if \(M\) is an interval \([x - R, x + R]\), \((x \in \mathbb{R}, R > 0)\), then
\[E_t(M) := [xe^{-t} - R, xe^{-t} + R],\]
is called continuous symmetrization.

The existence and uniqueness of the family \(E_t, 0 \leq t \leq +\infty\), has been proved in [6], Theorem 2.1.

**Definition 3:** (Continuous Steiner symmetrization (CStS))

(i) Let \(M \in \mathcal{M}(\mathbb{R}^N), (N \geq 2)\). The family of sets
\[(2.3) \ E_t(M) := \{x = (x_1, x') : x_1 \in E_t(M(x')), \ x' \in \mathbb{R}^{N-1}\}, \ 0 \leq t \leq +\infty,\]
is called the continuous Steiner symmetrization (CStS) of \(M\) (with respect to \(x_1\)).

(ii) Let \(u \in \mathcal{S}_+(\mathbb{R}^N)\). The family of functions \(E_t(u), 0 \leq t \leq +\infty\), defined by
\[(2.4) \ E_t(u)(x) := \begin{cases} \sup \{c > 0 : x \in E_t(\{u > c\})\} & \text{if } x \in \bigcup_{c>0} E_t(\{u > c\}) \\ 0 & \text{if } x \notin \bigcup_{c>0} E_t(\{u > c\}) \end{cases}, \ x \in \mathbb{R}^N,\]
is called CStS of \(u\) with respect to \(x_1\) in the case \(N \geq 2\) and continuous symmetrization in the case \(N = 1\).

**Remark 2.**

1. For convenience, we will henceforth simply write \(M^t\) and \(u^t\) for the sets \(E_t(M)\), respectively for the functions \(E_t(u), (t \in [0, +\infty])\).

2. It can be shown that, if \(M \in \mathcal{M}(\mathbb{R}^N)\) and \(M\) is open, then the sets \(M^t, (t \in [0, +\infty])\), have open representatives. This makes it possible to give pointwise definitions of open sets and of continuous functions:

(i) If \(M \in \mathcal{M}(\mathbb{R})\) is open and \(t \in [0, +\infty]\), then let
\[(2.5) \ M^{t,O} := \bigcup \{U : U \text{ is an open representative of } N^t, \ N \text{ open}, \ N \subset \subset M\} .\]

(ii) If \(M \in \mathcal{M}(\mathbb{R}^N), (N \geq 2)\), is open and \(t \in [0, +\infty]\), then let
\[(2.6) \ M^{t,O} := \{x = (x_1, x'): x_1 \in (M(x'))^{t,O}, \ x' \in \mathbb{R}^{N-1}\} .\]

Note that the relations \((2.5), (2.6)\) have to be understood in pointwise sense. The sets \(M^{t,O}\) in \((2.5)\) and \((2.6)\) are open and they are called the precise representatives of \(M^t\).

(iii) If \(u \in \mathcal{S}_+(\mathbb{R}^N)\) is continuous and \(t \in [0, +\infty]\), then there exists a unique continuous representative of \(u^t\) which is given by \((2.4)\) - now in pointwise sense! - where the sets \(\{u^t > c\}\) have to be replaced by their precise representatives.

From now on let us agree that, if we speak about the CStS of open sets or continuous
functions then we always mean their precise representatives.

**Remark 3.** Below we summarize basic properties of CStS, which have been proved by the author in [3], [6], \((M \in \mathcal{M}(\mathbb{R}^N), u, v \in \mathcal{L}_+(\mathbb{R}^N), t \in [0, +\infty])\).

1. **Equimeasurability:** From Definitions 2 and 3 we have

\[(2.7) \quad \mathcal{L}^N(M) = \mathcal{L}^N(M^t) \quad \text{and} \quad \{u^t > c\} = \{u > c\}^t \quad \forall c > 0.\]

2. **Monotonicity:** If \(u \leq v\) then \(u^t \leq v^t\).

3. If \(\psi : [0, +\infty) \rightarrow [0, +\infty)\) is bounded and nondecreasing with \(\psi(0) = 0\), then

\[(2.8) \quad \psi(u^t) = (\psi(u))^t.\]

4. **Homotopy:** We have

\[(2.9) \quad M^0 = M, \quad u^0 = u, \quad M^\infty = M^*, \quad u^\infty = u^*.\]

Furthermore, if \(M = M^*\) or \(u = u^*\), then we have \(M = M^t\), respectively \(u = u^t\). Finally, if \(t_n \rightarrow t\) as \(n \rightarrow +\infty\) and \(u \in L^p(\mathbb{R}^N)\) for some \(p \in [1, +\infty)\), then

\[(2.10) \quad \lim_{n \rightarrow \infty} \|u^{t_n} - u^t\|_p = 0.\]

5. **Cavalieri’s principle:** If \(F\) is continuous and if \(F(u) \in L^1(\mathbb{R}^N)\) then

\[(2.11) \quad \int_{\mathbb{R}^N} F(u) \, dx = \int_{\mathbb{R}^N} F(u^t) \, dx.\]

6. **Nonexpansivity in \(L^p\):** If \(u, v \in L^p(\mathbb{R}^N)\) for some \(p \in [1, +\infty)\) then

\[(2.12) \quad \|u^t - v^t\|_p \leq \|u - v\|_p.\]

7. **Hardy-Littlewood inequality:** If \(u, v \in L^2(\mathbb{R}^N)\) then

\[(2.13) \quad \int_{\mathbb{R}^N} u^t v^t \, dx \geq \int_{\mathbb{R}^N} uv \, dx.\]

8. A generalization of 5. and 7. is the following result:

Let \(u \in L^\infty(\mathbb{R}^N)\) and suppose that \(u\) vanishes outside some ball \(B_R, R > 0\). Furthermore, suppose that \(F = F(x, v)\) is bounded and measurable on \(B_R \times [0, +\infty)\), continuously differentiable in \(v\) with \(F(x, 0) = 0 \quad \forall x \in \mathbb{R}^N\), and \((\partial/\partial v)F(x, v)\) is even in \(x_1\) and nonincreasing in \(x_1\) for \(x_1 > 0\). Then

\[(2.14) \quad \int_{B_R} F(x, u) \, dx \leq \int_{B_R} F(x, u^t) \, dx.\]

9. If \(u\) is Lipschitz continuous with Lipschitz constant \(L\), then \(u^t\) is Lipschitz continuous, too, with Lipschitz constant less than or equal to \(L\).
10. If \( \text{supp } u \subset B_R \) for some \( R > 0 \), then we also have \( \text{supp } u^t \subset B_R \). If, in addition, \( u \) is Lipschitz continuous on \( \mathbb{R}^N \) with Lipschitz constant \( L \), then we have

\[
|u^t(x) - u(x)| \leq LRt \quad \forall x \in B_R \quad \text{and}
\]

\[
\int_{B_R} G(|\nabla u^t|) \, dx \leq \int_{B_R} G(|\nabla u|) \, dx,
\]

for every convex function \( G : [0, +\infty) \to [0, +\infty) \) with \( G(0) = 0 \).

Note that 1.-3., 5.-7., 9., and (2.16) are common properties of many rearrangements (see [22]).

The following symmetry criteria have been proved in [6], section 6.

**Lemma 1:** (see [6], Theorem 6.2) Let \( \Omega \) be a bounded open set, \( u \in C^1(\Omega) \cap C(\overline{\Omega}) \), \( u > 0 \) in \( \Omega \) and \( u = 0 \) on \( \partial \Omega \). Furthermore, let \( G : [0, +\infty) \to [0, +\infty) \) be strictly convex with \( G(0) = 0 \), and suppose that

\[
\lim_{t \to 0} \frac{1}{t} \left( \int_{\Omega} G(|\nabla u|) \, dx - \int_{\Omega^t} G(|\nabla u^t|) \, dx \right) = 0.
\]

Then \( u \) satisfies the following symmetry property:
If \( y = (y_1, y') \in \mathbb{R}^N \) with

\[
0 < u(y) < \sup u, \quad \frac{\partial u}{\partial x_1}(y) > 0,
\]

and \( \tilde{y} \) is the (unique) point satisfying

\[
\tilde{y} = (\tilde{y}_1, y'), \quad \tilde{y}_1 > y_1, \quad u(y) = u(\tilde{y}) < u(z, y') \quad \forall z \in (y_1, \tilde{y}_1),
\]

then

\[
\frac{\partial u}{\partial x_i}(y) = \frac{\partial u}{\partial x_i}(\tilde{y}), \quad i = 1, \ldots, N - 1, \quad \text{and}
\]

\[
\frac{\partial u}{\partial x_1}(y) = -\frac{\partial u}{\partial x_1}(\tilde{y}).
\]

We will say that \( u \) is locally symmetric in direction \( x_1 \) if \( u \) satisfies the properties (2.18)-(2.20).

**Lemma 2:** (see [6], Theorem 6.1) Let \( \Omega \), \( u \) and \( G \) be as in Lemma 1, and suppose that for arbitrary rotations \( x \mapsto y = (y_1, y') \) of the coordinate system, \( u \) is locally symmetric in direction \( y_1 \). Then \( \Omega \) is an at most countable union of mutually disjoint open balls and \( u \) satisfies the symmetry properties (1.6).
3. Symmetry of the solution

In this section we show Theorem 1. The idea is to use appropriate test functions \( v \) in (1.7) and then to use Lemma 1. This works well in the case of Steiner symmetric domains \( \Omega \) (see [6]), choosing \( v = u^t \), respectively \( v = u \), \((u^t: \text{CStS of } u, \text{with small } t > 0)\). However, in our situation, \( \Omega \) is not assumed to be symmetric, so that \( u^t \) might not vanish on \( \partial \Omega \).

Therefore we modify the approach of [6], using appropriate cut-off functions of \( u^t \) and \( u \).

First we introduce some notation. For functions \( v \) we write \( v^+ := \max\{v, 0\} \).

By the symbol \( o(t) \) we denote any function satisfying \( \lim_{t \to 0} o(t)/t = 0 \) and which may vary from line to line. For any point \( x \in \Omega \) we write \( d(x) := \text{dist}\{x; \partial \Omega\} \equiv \inf\{|x - z|: z \in \partial \Omega\} \).

Throughout this section, let \( u \) be the solution of problem (1.3)-(1.8). For convenience, we extend \( u \) by zero outside \( \Omega \), so that \( u \in \mathbb{C}_0^1(\mathbb{R}^N) \). We denote by \( L \) the Lipschitz constant of \( u \), and we set \( u_0 := \max\{u(x): x \in \Omega\} \). We choose a number \( R > 0 \) such that \( \overline{\Omega} \subset B_R \), and we set \( f_0 := \sup\{|f(|x|, v)|: |x| \leq R, 0 \leq v \leq u_0\} \) and \( k := 2RL \).

Finally, we fix some coordinate system \( x = (x_1, x') \), \((x_1 \in \mathbb{R}, x' \in \mathbb{R}^{N-1})\).

Let \( u^t \), \((0 \leq t \leq +\infty)\), denote the CStS of \( u \) with respect to \( x_1 \). Since \( u \in \mathbb{C}^{0,1}(\mathbb{R}^N) \), we have by Remark 2, 9. and by (2.15),

\[
(3.1) \quad u^t \in \mathbb{C}^{0,1}(\mathbb{R}^N),
\]

\[
(3.2) \quad u^t \text{ has Lipschitz constant less than or equal to } L, \text{ and}
\]

\[
(3.3) \quad |u^t(x) - u(x)| \leq LRt \quad \forall t \in [0, +\infty],
\]

Next we obtain some estimates for \( u \) and \( u^t \) near the boundary of \( \Omega \).

Since \( u \) is positive in \( \Omega \) and continuous on \( \mathbb{R}^N \), and since \( \Omega \) is bounded, we have

\[
(3.4) \quad \lim_{s \to 0} \sup_{\{0 < u(x) \leq s\}} d(x) = 0.
\]

**Lemma 3:** Let \( t \in [0, +\infty) \) and \( u^t(x) > kt \). Then \( x \in \Omega \).

**Proof:** We have by property (3.3),

\[
 u(x) \geq -|u(x) - u^t(x)| + u^t(x) \geq -RLt + kt = RLt > 0.
\]

Hence \( x \in \Omega \).

For convenience, we set

\[
(3.5) \quad M_1(t) := \{0 < u \leq kt\} \quad \text{and}
\]

\[
(3.6) \quad M_2(t) := \Omega \cap \{0 < u^t \leq kt\}, \quad (t \in (0, +\infty)).
\]
Note that \( M_1(t), M_2(t) \subset \Omega \), and by Remark 3, 1.,
\[(3.7) \quad \mathcal{L}^N(M_1(t)) = \mathcal{L}^N(M_2(t)) \quad \forall t \in (0, +\infty).\]

**Lemma 4:** There holds:
\[(3.8) \quad \lim_{t \to 0} \sup \{d(x) : x \in M_1(t) \cup M_2(t)\} = 0.\]

**Proof:** In view of property (3.4) it is sufficient to show that
\[(3.9) \quad \lim_{t \to 0} \sup \{d(x) : x \in M_2(t)\} = 0.\]
Assume that (3.9) is not true. Then there exists a number \( \delta > 0 \), a sequence of points \( \{x_n\} \subset \Omega \) and a decreasing sequence \( \{t_n\} \subset \mathbb{R} \) with \( \lim_{n \to \infty} t_n = 0 \), such that \( 0 < u^{t_n}(x_n) \leq kt_n \), but \( d(x_n) \geq \delta \). The latter also implies that \( u(x_n) \geq \varepsilon \), for some \( \varepsilon > 0 \). On the other hand, we have by (2.15),
\[u(x_n) \leq |u(x_n) - u^{t_n}(x_n)| + u^{t_n}(x_n) \leq LRt_n + kt_n \to 0,\]
as \( n \to \infty \), a contradiction. \( \square \)

**Lemma 5:** There exists a constant \( c_0 > 0 \) such that
\[(3.10) \quad \mathcal{L}^N(M_1(t)) \leq c_0 t, \quad (0 < t < +\infty).\]

**Proof:** By (1.5) and (3.4) there exist positive numbers \( \tau \) and \( t_0 \), such that
\[(3.11) \quad |\nabla u(x)| \geq \tau \quad \text{if} \quad x \in M_1(t_0).\]
By the Implicit Function Theorem, we have that for every \( s \in (0, kt_0) \), \( \{u > s\} \) is an open subset of \( \Omega \) and \( \partial \{u > s\} = \{u = s\} \), and \( \{u = s\} \) is locally a \( C^1 \)-hypersurface. Integrating (1.3) over \( \{u > s\} \), \( (s \in (0, kt_0)) \), Green’s Theorem yields
\[\int_{\{u=s\}} g(|\nabla u|) d\mathcal{H}^{N-1}(x) = \int_{\{u>s\}} f(|x|, u) \, dx.\]
By (3.11) this implies
\[(3.12) \quad \int_{\{u=s\}} d\mathcal{H}^{N-1}(x) \leq \frac{f_0}{g(\tau)} \mathcal{L}^N(\Omega), \quad (s \in (0, kt_0)).\]
Using this and the co-area formula (see [14]), we obtain:
\[\mathcal{L}(M_1(t)) = \int_0^{kt} \left( \int_{\{u=s\}} d\mathcal{H}^{N-1}(x) \right) ds \leq \frac{1}{\tau} \int_0^{kt} \left( \int_{\{u=s\}} d\mathcal{H}^{N-1}(x) \right) ds \leq \frac{f_0}{\tau g(\tau)} \mathcal{L}^N(\Omega) kt, \quad (t \in (0, t_0)),\]
and the assertion follows. □

Proof of Theorem 1: The functions \((u^t - kt)_+\) have compact support in \(\overline{\Omega}\) for all \(t \in [0, +\infty]\), by Lemma 3. Hence we derive from (1.3) the integral identities

\[
0 = \int_{\Omega} g(|\nabla u|) \frac{\nabla u}{|\nabla u|} \cdot \nabla ((u^t - kt)_+ - (u - kt)_+) \, dx
- \int_{\Omega} f(|x|, u) ((u^t - kt)_+ - (u - kt)_+) \, dx
\]

(3.13) \(\equiv I_1(t) - I_2(t), \quad t \in [0, +\infty)\).

First we claim that

(3.14) \(I_2(t) \geq o(t)\).

To show (3.14), we split \(I_2(t)\) for \(0 < t \leq \frac{u_0}{k}\):

\[
I_2(t) = \int_{M_t(t)} \left( f(|x|, u) - f(|x|, kt) \right) ((u^t - kt)_+ - (u - kt)_+) \, dx
+ \int_{\Omega} f(|x|, (u - kt)_+ + kt) ((u^t - kt)_+ - (u - kt)_+) \, dx
\]

(3.15) \(\equiv I_{21}(t) + I_{22}(t)\).

By (3.3) we have

(3.16) \(|(u^t(x) - kt)_+ - (u(x) - kt)_+| \leq LRt \quad \forall x \in \Omega\).

It follows from Lemma 5 and (3.16), that for \(0 < t \leq \frac{u_0}{k}\),

(3.17) \(|I_{21}(t)| \leq \frac{2}{\tau} f_0 LR c_0 t^2\).

Further, in view of (2.8) we have

\((u^t - kt)_+ + kt = ((u - kt)_+ + kt)^t\).

Hence we obtain by using Remark 3, 8.,

\[
0 \leq \int_{\Omega} \left( F(|x|, (u^t - kt)_+ + kt) - F(|x|, (u - kt)_+ + kt) \right) \, dx
= \int_{\Omega} \int_0^1 f(|x|, u^t_\theta) \, d\theta \left( (u^t - kt)_+ - (u - kt)_+ \right) \, dx,
\]

(3.18) ...(continued)
where

\[ F(r,v) := \int_0^v f(r,w) \, dw, \quad (r,v \geq 0), \quad \text{and} \]

\[ u^t_\theta := (1 - \theta)(u - kt)_+ + \theta(u^t - kt)_+ + kt, \quad (\theta \in [0, 1]). \]

Using (3.16), we obtain,

\[ |u^t_\theta(x) - (u(x) - kt)_+ - kt| \leq \theta |u^t(x) - u(x)| \leq \theta LRt \]
\[ \forall x \in \mathbb{R}^N, \theta \in [0, 1]. \]

Since the mapping \( v \mapsto f(r,v) \) is continuous, uniformly in \( r \), this implies

\[ \limsup_{t \to 0} \left\{ |f(|x|, u^t_\theta(x)) - f(|x|, (u(x) - kt)_+ + kt)| : x \in \Omega, \theta \in [0, 1] \right\} = 0. \]

Finally, (3.16) and (3.18) yield, for \( 0 < t \leq u_0/k \),

\[ I_{22}(t) \geq \int_\Omega \left\{ f(|x|, (u - kt)_+ + kt) - \int_0^1 f(|x|, u^t_\theta) \, d\theta \right\} (u^t - kt)_+ - (u - kt)_+ \, dx \]
\[ \geq - \sup \left\{ |f(|x|, u^t_\theta) - f(|x|, (u - kt)_+ + kt)| : x \in \Omega, \theta \in [0, 1] \right\} \cdot LRt \cdot \mathcal{L}^N(\Omega). \]

Now (3.14) follows from (3.17), (3.19) and (3.20).

Next we estimate \( I_1(t) \). Let

\[ G(z) := \int_0^z g(s) \, ds \quad \text{and} \]
\[ h(z) := G(z) - zg(z), \quad (z \geq 0). \]
Note that $h$ is nonincreasing. Since $G$ is convex, we have for $t \in (0, u_0/k]$,

\begin{align}
I_1(t) &= \int_{\Omega \setminus M_2(t)} g(|\nabla u|) \frac{\nabla u \cdot \nabla u^t}{|\nabla u|} \, dx - \int_{\Omega \setminus M_1(t)} g(|\nabla u|)|\nabla u| \, dx \\
&\leq \int_{\Omega \setminus M_2(t)} g(|\nabla u|)|\nabla u^t| \, dx - \int_{\Omega \setminus M_1(t)} g(|\nabla u|)|\nabla u| \, dx \\
&\leq \int_{\Omega \setminus M_2(t)} (G(|\nabla u^t|) - G(|\nabla u|) + g(|\nabla u|)|\nabla u|) \, dx \\
&\quad - \int_{\Omega \setminus M_1(t)} g(|\nabla u|)|\nabla u| \, dx \\
&= \int_{\Omega \setminus M_2(t)} G(|\nabla u^t|) \, dx - \int_{\Omega \setminus M_1(t)} G(|\nabla u|) \, dx \\
&\quad + \int_{M_2(t)} h(|\nabla u|) \, dx - \int_{M_1(t)} h(|\nabla u|) \, dx \\
&= : I_{11}(t) - I_{12}(t) + I_{13}(t) - I_{14}(t), \quad t \in [0, +\infty).
\end{align}

By Lemma 4 and (1.5) we have

\begin{equation}
\limsup_{t \to 0} \{||\nabla u(x)| - \lambda(|x|)| : x \in M_1(t) \cup M_2(t)\} = 0.
\end{equation}

Furthermore, since $\lambda$ is nondecreasing and since $h(z) := G(z) - zg(z)$, ($z \in [0, +\infty)$), is nonincreasing, the function

$$p(x) := h(\lambda(|x|)), \quad (x \in \mathbb{R}^N),$$

satisfies $p = p^* = p^t \quad \forall t \in [0, +\infty]$. Applying the Hardy-Littlewood inequality (2.13) we obtain for $t \in (0, u_0/k]$,

\begin{align}
\int_{\Omega \setminus M_1(t)} p \, dx &= \int_{\mathbb{R}^N} p\chi_{(\Omega \setminus M_1(t))} \, dx \\
&\leq \int_{\mathbb{R}^N} p\chi_{(\Omega \setminus M_2(t))} \, dx = \int_{\Omega \setminus M_2(t)} p \, dx.
\end{align}
In view of (3.7), Lemma 5, (3.22) and (3.23) we obtain for \( t \in (0,u_0/k] \),
\[
I_{12}(t) - I_{13}(t) = - \int_{M_1(t)} p\,dx + \int_{M_2(t)} p\,dx \\
+ \int_{M_1(t)} (p(x) - h\,(|\nabla u|))\,dx - \int_{M_2(t)} (p(x) - h\,(|\nabla u|))\,dx
\]
\[
\leq 22^{\mathcal{L}^N}(M_1(t))\sup\{|p(x) - h\,(|\nabla u(x)|)| : x \in M_1(t) \cup M_2(t)\}
\leq 2c_0t\sup\{|p(x) - h\,(|\nabla u(x)|)| : x \in M_1(t) \cup M_2(t)\} = o(t).
\]

(3.24)

In conclusion, we have by (3.14), (3.15), (3.21) and (3.24) for \( t \in (0,u_0/k] \),
\[
(3.25) \quad \int_{\Omega} G(|\nabla(u^t - kt)|)\,dx \geq o(t).
\]

Now fix \( \varepsilon \in (0,u_0] \). Setting \( w(x) := \min\{(u(x) - kt)_+; \varepsilon - kt\} \) for \( t \in (0,u_0/k] \) and \( x \in \mathbb{R}^N \), we have by (2.16),
\[
(3.26) \quad \int_{\Omega} G(|\nabla w^t|)\,dx \leq \int_{\Omega} G(|\nabla w|)\,dx.
\]

Since \( w^t(x) = \min\{(u^t(x) - kt)_+; \varepsilon - kt\} \), \( x \in \mathbb{R}^N \), (3.26) together with (3.25) gives for \( t \in (0,u_0/k] \),
\[
\int_{\Omega} \left(G(|\nabla(u^t - \varepsilon)_+|) - G(|\nabla(u - \varepsilon)_+|)\right)\,dx
= \int_{\Omega} \left(G(|\nabla w|) - G(|\nabla w^t|)\right)\,dx \\
+ \int_{\Omega} \left(G(|\nabla(u^t - kt)_+|) - G(|\nabla(u - kt)_+|)\right)\,dx
\geq \int_{\Omega} \left(G(|\nabla(u^t - kt)_+|) - G(|\nabla(u - kt)_+|)\right)\,dx \geq o(t).
\]

(3.27)

In view of Lemma 1, \((u - \varepsilon)_+\) is locally symmetric in direction \( x_1 \). Since the same estimate (3.27) can be obtained for CStS in arbitrary directions, Lemma 2 tells us that \( \{u > \varepsilon\} \) is an at most countable union of mutually disjoint open balls and \((u - \varepsilon)_+\) satisfies the symmetry property (1.6) of Theorem 1. Since \( \varepsilon \) was arbitrary, \( u \) is locally symmetric in every direction, too. Moreover, since \( \Omega = \bigcup_{\varepsilon > 0} \{u > \varepsilon\} \), and \( \Omega \) is connected, it must be a ball. The Theorem is proved.

\( \square \)

**Remark 4.** It is often possible to derive the radial symmetry of the solution of (1.3), (1.4)
from their local symmetry by using other well-known tools (see [6], section 10, and [7]). For instance, in the case of the \( p \)-Laplacian, i.e. if \( g(z) = z^{p-1} \) for some \( p > 1 \), \( u \) is radially symmetric if \( f(|x|, \cdot) \) satisfies some growth conditions in neighbourhoods of its zero points (see [7], Theorem 1).

We mention three typical situations for a general \( g \):

**Theorem 2:** Let \( \Omega, f, g, \lambda \) and \( u \) be as in Theorem 1, and suppose that one of the following conditions (a), (b), (c) is satisfied:

(a) \( f \) is nonnegative,

(b) the mapping \( r \mapsto f(r, v) \) is strictly decreasing,

(c) \( f \) is independent of \( x \) and the mapping \( w \mapsto f(w) \) is nonincreasing.

Then \( u \) is radially symmetric and radially decreasing, i.e. \( \Omega = B_R(y) \) for some \( R > 0 \) and \( y \in \mathbb{R}^N \), and

\[
(3.28) \quad u = u(r), \quad \frac{\partial u}{\partial r} \leq 0, \quad (r = |x - y|).
\]

Moreover, we have \( y = 0 \) in case (b).

**Proof:** We use the notations of (1.6).

(a) If \( r_k > 0 \) for some \( k \in \{1, \ldots, m\} \), we have by Green’s Theorem,

\[
\int_{B_{r_k}(y^k)} f(|x|, u) \, dx = \int_{\partial B_{r_k}(y^k)} g(|\nabla u|) \, d\mathcal{H}^{N-1}(x) = 0,
\]

which means that \( f \equiv 0 \) and hence \( u = \text{const} \) in \( B_{r_k}(y^k) \). Since \( u \) is positive, this implies that we must have \( m = 1 \). Moreover, if \( r_1 > 0 \), then we must have \( u = \text{const} \) in \( B_{r_1}(y^1) \).

(b) If the mapping \( r \mapsto f(r, v) \) is strictly decreasing, then (1.3) shows that we must have \( y^k = 0, (k = 1, \ldots, m) \), which proves (3.28), with \( y = 0 \).

(c) Let \( \Sigma \) be an arbitrary \((N - 1)\)-hyperplane containing the centre \( y \) of the ball \( \Omega \). Denote by \( H \) one of the two open halfspaces into which \( \mathbb{R}^N \) is split by \( \Sigma \), and let \( \sigma \) denote reflection in \( \Sigma \). Define

\[
v(x) := u(\sigma x), \quad (x \in \Omega \cap H).
\]

Since

\[
\left( g(|y|) \frac{y}{|y|} - g(|z|) \frac{z}{|z|} \right) \cdot (y - z) \geq 0
\]

for all vectors \( y, z \in \mathbb{R}^N \), and since the mapping \( w \mapsto f(w) \) is nonincreasing, we obtain

\[
0 \leq \int_{\Omega \cap H} \left( g(|\nabla u|) \frac{\nabla u}{|\nabla u|} - g(|\nabla v|) \frac{\nabla v}{|\nabla v|} \right) \cdot \nabla (u - v) \, dx
\]

\[
= \int_{\Omega \cap H} (f(u) - f(v))(u - v) \, dx \leq 0.
\]

Hence \( u = v \) in \( \Omega \cap H \). Since \( \Sigma \) was arbitrary, the assertion follows. \( \square \)
