Abstract

Given an arbitrary $2^w \times 2^w$ unitary matrix $U$, a powerful matrix decomposition can be applied, leading to four different syntheses of a $w$-qubit quantum circuit performing the unitary transformation. The demonstration is based on a recent theorem by Führ and Rzeszotnik, generalizing the scaling of single-bit unitary gates ($w = 1$) to gates with arbitrary value of $w$. The synthesized circuit consists of controlled 1-qubit gates, such as NEGATOR gates and PHASOR gates. Interestingly, the approach reduces to a known synthesis method for classical logic circuits consisting of controlled NOT gates, in the case that $U$ is a permutation matrix.

1 Introduction

The group $U(2^w)$, i.e. the group of $2^w \times 2^w$ unitary matrices, describes all quantum circuits acting on $w$ qubits [1]. In the literature, many different decompositions of a unitary matrix $U$ have been proposed to synthesize quantum circuits performing the transformation $U$. These decompositions
can be classified into two categories. The first category of decompositions reduces the dimension of the unitary matrix with one unit, leading to a matrix sequence $U(n), U(n - 1), U(n - 2), \ldots$ all the way down to $U(2)$. Notable examples are based on beam-splitter transformations [2] or the Householder decompositions [3, 4, 5]. Although these decompositions can be realized physically by means of multi-beam splitters or Mach-Zehnder interferometers [2], they are not in natural accordance with a multi-qubit architecture.

For this, the second category of decompositions is better suited, to which the cosine-sine (CSD) [6], Cartan’s KAK [7, 8], Clifford-T [9, 10], and related decompositions [11, 12] belong. This category reduces a unitary transformation on $w$ qubits, or $w$-qubit gate, to a cascade of unitary transformations on $(w - 1)$-qubits.

Recently, it was demonstrated [13], in the framework of the ZXZ matrix decomposition, that two subgroups of $U(n)$ are helpful:

- $XU(n)$, the group of $n \times n$ unitary matrices with all line sums equal to 1;
- $ZU(n)$, the group of $n \times n$ diagonal unitary matrices with upper-left entry equal to 1.

They allow the implementation of quantum circuits [14], with the help of $2 \times 2$ PHASOR gates and $j \times j$ Fourier-transform gates with $2 \leq j \leq 2^w$, which can be realised respectively as phase shifters and as $2n$-multiports in $n$-mode quantum-optical circuits [2, 15, 16]. However compact and elegant in mathematical form, the ZXZ decomposition belongs to the first category of decompositions, and is not naturally tailored to qubit-based quantum circuits. This is due to the presence of the $j \times j$ Fourier transforms, which act on a $j$-dimensional subspace of the total $2^w$ Hilbert space, rather than on a subset of the $w$ qubits. The reason for this is the decomposition of an arbitrary $XU(j)$ matrix as

$$F_j \begin{pmatrix} 1 \\ U \end{pmatrix} F_j,$$

where $F_j$ is the $j \times j$ Fourier matrix and $U$ is an appropriate $U(j - 1)$ matrix. Hence, the size of the matrix to be synthesized lowers only one unit: from $j$ to $j - 1$.

Below we will demonstrate that a similar but more natural ZXZ-inspired method exists which respects the qubit structure of the quantum circuit to be synthesized. At each step, the size of the unitary matrix is reduced by a factor $1/2$, so instead of a matrix sequence from $U(n), U(n - 1), U(n - \ldots$
2),... we will take matrices from $U(n)$, $U(n/2)$, $U(n/4)$,... On the one hand, this means that the method is not applicable for arbitrary $n$, but only useful for $n$ equal to some power of 2, i.e. for $n = 2^w$. On the other hand, the decomposition is more in line with classical reversible decompositions, respecting the bit-structure of the architecture [17]. Indeed, we will also prove that the proposed block-ZXZ decomposition leads to the Birkhoff decomposition of classical reversible circuits when the unitary matrix is a permutation matrix, in contrast to previously proposed methods [6, 7, 8, 9, 10, 11, 12].

2 Circuit decomposition

De Vos and De Baerdemacker [13, 18] noticed the following decomposition of an arbitrary member $U$ of $U(2)$:

$$U = \begin{pmatrix} a & 0 \\ 0 & b \end{pmatrix} \frac{1}{2} \begin{pmatrix} 1 + c & 1 - c \\ 1 - c & 1 + c \end{pmatrix} \begin{pmatrix} 1 & 0 \\ 0 & d \end{pmatrix},$$

(1)

where $a$, $b$, $c$, and $d$ are complex numbers with unit modulus. Idel and Wolf [16] proved a generalization, conjectured in [18], for an arbitrary element $U$ of $U(n)$ with arbitrary $n$:

$$U = Z_1 X Z_2,$$

where $Z_1$ is an $n \times n$ diagonal unitary matrix, $X$ is an $n \times n$ unitary matrix with all line sums equal to 1, and $Z_2$ is an $n \times n$ diagonal unitary matrix with upper-left entry equal to 1. Führ and Rzeszotnik [19] proved another generalization for an arbitrary element $U$ of $U(n)$, however restricted to even $n$ values:

$$U = \begin{pmatrix} A & 0 \\ 0 & B \end{pmatrix} \frac{1}{2} \begin{pmatrix} I + C & I - C \\ I - C & I + C \end{pmatrix} \begin{pmatrix} I & 0 \\ 0 & D \end{pmatrix},$$

(2)

where $A$, $B$, $C$, and $D$ are matrices from $U(n/2)$ and $I$ is the $n/2 \times n/2$ unit matrix. We note that, in both generalizations, the number of degrees of freedom is the same in the lhs and rhs of the equation. In the former case we have

$$n^2 = n + (n - 1)^2 + (n - 1);$$

in the latter case we have

$$n^2 = 2 \left( \frac{n}{2} \right)^2 + \left( \frac{n}{2} \right)^2 + \left( \frac{n}{2} \right)^2.$$
If $n$ equals $2^w$, then the decomposition (2) allows a circuit interpretation. Indeed, we can write

$$
\begin{pmatrix}
I + C & I - C \\
I - C & I + C
\end{pmatrix} = F
\begin{pmatrix}
I \\
C
\end{pmatrix} F^{-1},
$$

where $F$ is the following $n \times n$ complex Hadamard matrix [20]:

$$
F = \frac{1}{\sqrt{2}}
\begin{pmatrix}
I & I \\
I & -I
\end{pmatrix} = H \otimes I,
$$

with $I$ being again the $n/2 \times n/2$ unit matrix, and $H$ the $2 \times 2$ Hadamard matrix. We conclude that an arbitrary quantum circuit acting on $w$ qubits can be decomposed into two Hadamard gates and four quantum circuits acting on $w - 1$ qubits and controlled by the remaining qubit:

$$
U = \begin{array}{c}
\bigg(\begin{array}{c}
H \\
D \\
C \\
B \\
A
\end{array}\bigg)
\end{array}.
$$

We now can apply the above decomposition to each of the four circuits $A$, $B$, $C$, and $D$. By acting so again and again, we finally obtain a decomposition into

- $h = 2(4^w - 1)/3$ Hadamard gates, and
- $g = 4^w - 1$ non-Hadamard quantum gates acting on a single qubit.

As the former gates have no parameter and each of the latter gates has four parameters, the circuit has $4g = 4^w$ parameters, in accordance with the $n^2$ degrees of freedom of the matrix $U$. We note that all $h + g$ single-qubit gates are controlled gates, with the exception of two Hadamard gates on the first qubit.

One might continue the decomposition by decomposing each single-qubit circuit into exclusively **NEGATOR** gates and **PHASOR** gates. Indeed, we can rewrite (1) as

$$
U = \begin{pmatrix}
0 & 1 \\
1 & 0
\end{pmatrix}
\begin{pmatrix}
1 & 0 \\
0 & a
\end{pmatrix}
\begin{pmatrix}
1 & 0 \\
0 & b
\end{pmatrix}
\frac{1}{2}
\begin{pmatrix}
1 + c & 1 - c \\
1 - c & 1 + c
\end{pmatrix}
\begin{pmatrix}
1 & 0 \\
0 & d
\end{pmatrix},
$$
i.e. a cascade of three PHASOR gates and three NEGATOR gates. Two of the latter are simply NOT gates. In particular for the Hadamard gate, we have

\[
H = \begin{pmatrix}
0 & 1 \\
1 & 0
\end{pmatrix}
\begin{pmatrix}
1 & 0 \\
0 & (1-i)/\sqrt{2}
\end{pmatrix}
\begin{pmatrix}
0 & 1 \\
1 & 0
\end{pmatrix}
\begin{pmatrix}
1 & 0 \\
0 & (1+i)/\sqrt{2}
\end{pmatrix}
\frac{1}{2}
\begin{pmatrix}
1+i & 1-i \\
1-i & 1+i
\end{pmatrix}
\begin{pmatrix}
1 & 0 \\
0 & i
\end{pmatrix}.
\]

Among the 3h + 3g NEGATORS, 2h + 2g are NOTs and h are square roots of the NOT.

3 Group structure

We note that the U(n) matrices with all line sums equal to 1 form the subgroup XU(n) of U(n). For even n, the XU(n) matrices of the particular block type

\[
\frac{1}{2}
\begin{pmatrix}
I + V & I - V \\
I - V & I + V
\end{pmatrix},
\]

with V ∈ U(n/2), form a subgroup \( bXU(n) \) of XU(n):

\[
U(n) \supset XU(n) \supset bXU(n),
\]

with respective dimensions

\[
n^2 > (n-1)^2 \geq n^2/4.
\]

The group structure of \( bXU(n) \) follows directly from the group structure of the constituent unitary matrix:

\[
\frac{1}{2}
\begin{pmatrix}
I + V_1 & I - V_1 \\
I - V_1 & I + V_1
\end{pmatrix}
\frac{1}{2}
\begin{pmatrix}
I + V_2 & I - V_2 \\
I - V_2 & I + V_2
\end{pmatrix} = \frac{1}{2}
\begin{pmatrix}
I + V_1V_2 & I - V_1V_2 \\
I - V_1V_2 & I + V_1V_2
\end{pmatrix},
\]

thus demonstrating the isomorphism \( bXU(n) \cong U(n/2) \).

We note that the diagonal U(n) matrices with upper-left entry equal to 1 form the subgroup ZU(n) of U(n). For even n, the U(n) matrices of the particular block type

\[
\begin{pmatrix}
I \\
V
\end{pmatrix},
\]

with V ∈ U(n/2), form a group \( bZU(n) \), also a subgroup of U(n). The group structure of \( bZU(n) \) thus follows trivially from the group structure of U(n/2).

\footnote{We use \( bXU \) and \( bZU \) as short notations for the block-structured XU matrices and the block-structured ZU matrices, respectively.}
Whereas \( \text{bXU}(n) \) is a subgroup of \( \text{XU}(n) \), \( \text{bZU}(n) \) is neither a subgroup nor a supergroup of \( \text{ZU}(n) \). Whereas \( \dim(\text{bXU}(n)) \leq \dim(\text{XU}(n)) \), the dimension of \( \text{bZU}(n) \), i.e. \( n^2/4 \), is greater than or equal to the dimension of \( \text{ZU}(n) \), i.e. \( n - 1 \).

It has been demonstrated \[21\] that the closure of \( \text{XU}(n) \) and \( \text{ZU}(n) \) is the whole group \( \text{U}(n) \). In other words, any member of \( \text{U}(n) \) can be written as a product of \( \text{XU} \) matrices and \( \text{ZU} \) matrices. Provided \( n \) is even, a similar property holds for the block versions of \( \text{XU} \) and \( \text{ZU} \): the closure of \( \text{bXU}(n) \) and \( \text{bZU}(n) \) is the whole group \( \text{U}(n) \). Indeed, with the help of the identity

\[
\begin{pmatrix} A & B \\ I & I \end{pmatrix} = \begin{pmatrix} I & I \\ I & A \end{pmatrix} \begin{pmatrix} I & I \\ I & B \end{pmatrix},
\]

we can transform the decomposition \[2\] into a product containing exclusively \( \text{bXU} \) and \( \text{bZU} \) matrices, with (among others) the particular \( \text{bXU} \) matrix \( \begin{pmatrix} I & I \\ I & I \end{pmatrix} \), i.e. the block \( \text{NOT} \) gate.

### 4 Dual decomposition

Let \( U \) be an arbitrary member of \( \text{U}(n) \). We apply the Führ–Rzeszotnik theorem not to \( U \) but instead to its Fourier–Hadamard conjugate \( u = \text{FUF} \):

\[
u = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \text{F} \begin{pmatrix} I & 0 \\ 0 & I \end{pmatrix} \text{F} \begin{pmatrix} I & 0 \\ 0 & I \end{pmatrix} \text{F},
\]

We decompose the left factor and insert the \( \text{FF} \) product, equal to the \( n \times n \) unit matrix \( \begin{pmatrix} I & I \\ I & I \end{pmatrix} \):

\[
U = \text{F}u\text{F} = \text{F} \begin{pmatrix} I & 0 \\ 0 & I \end{pmatrix} \text{FF} \begin{pmatrix} a & b \\ c & d \end{pmatrix} \text{F} \begin{pmatrix} I & 0 \\ 0 & I \end{pmatrix} \text{F} \begin{pmatrix} I & 0 \\ 0 & I \end{pmatrix} \text{F}.
\]

Because \( \text{F} \begin{pmatrix} a & b \\ c & d \end{pmatrix} \text{F} = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \), we obtain:

\[
U = \text{F} \begin{pmatrix} I & 0 \\ 0 & I \end{pmatrix} \text{F} \begin{pmatrix} a & b \\ c & d \end{pmatrix} \text{F} \begin{pmatrix} I & 0 \\ 0 & I \end{pmatrix} \text{F} \begin{pmatrix} I & 0 \\ 0 & I \end{pmatrix} \text{F},
\]

a decomposition of the form

\[
U = \frac{1}{2} \left( \begin{pmatrix} I & A' \\ I - A' & I + A' \end{pmatrix} \right) \left( \begin{pmatrix} B' & C' \\ I - D' & I + D' \end{pmatrix} \right) \frac{1}{2} \left( \begin{pmatrix} I & D' \\ I - D' & I + D' \end{pmatrix} \right),
\]

with

\[
A' = ba^{-1}, \ B' = a, \ C' = ac, \text{ and } D' = d.
\]
We thus obtain a decomposition of the form $bXbZbX$, dual to the Führ–Rzeszotnik decomposition of the form $bZbXbZ$. Just like in the $bZbXbZ$ decomposition, the number of degrees of freedom in the $bXbZbX$ decomposition exactly matches the dimension $n^2$ of the matrix $U$. The diagram of the dual decomposition looks like

$$U = \begin{array}{cccc}
H & H & H & H \\
D' & C' & B' & A'
\end{array}.$$

5 Detailed procedure

Section 2 provides the outline for the synthesis of an arbitrary quantum circuit acting on $w$ qubits, given its unitary transformation (i.e. its $2^w \times 2^w$ unitary matrix). However, the synthesis procedure is only complete if, given the matrix $U$, we are able to actually compute the four matrices $A$, $B$, $C$, and $D$.

It is well-known that an arbitrary member $U$ of $U(2)$ can be written with the help of four real parameters:

$$U = \begin{pmatrix}
\cos(\phi)e^{i(\alpha+\psi)} & \sin(\phi)e^{i(\alpha+\chi)} \\
-\sin(\phi)e^{i(\alpha-\chi)} & \cos(\phi)e^{i(\alpha-\psi)}
\end{pmatrix}.$$

De Vos and De Baerdemacker [13, 18] noticed two different decompositions of this matrix according to [14]: In the former decomposition, we have

\begin{align*}
a &= e^{i(\alpha+\phi+\psi)} \\
b &= ie^{i(\alpha+\phi-\chi)} \\
c &= e^{-2i\phi} \\
d &= -ie^{i(-\psi+\chi)} ,
\end{align*}

whereas in the latter decomposition, we have

\begin{align*}
a &= e^{i(\alpha-\phi+\psi)} \\
b &= -ie^{i(\alpha-\phi-\chi)} \\
c &= e^{2i\phi} \\
d &= ie^{i(-\psi+\chi)} .
\end{align*}
Führ and Rzeszotnik proved the generalization (2) for an arbitrary element

\[ U = \begin{pmatrix} U_{11} & U_{12} \\ U_{21} & U_{22} \end{pmatrix} \]

of \( U(n) \), for even \( n \) values, by introducing for each of the four \( n/2 \times n/2 \) matrix blocks \( U_{11}, U_{12}, U_{21}, \) and \( U_{22} \) of \( U \), the polar decomposition

\[ U_{jk} = P_{jk} V_{jk}, \]

where \( P_{jk} \) is a positive-semidefinite Hermitian matrix and \( V_{jk} \) is a unitary matrix. Close inspection of the proof by Führ and Rzeszotnik (i.e. the proof to Theorem 8.1 in [19]) reveals the following expressions:

\[
\begin{align*}
A &= (P_{11} + i P_{12}) V_{11} \\
B &= (P_{21} - i P_{22}) V_{21} \\
C &= V_{11}^\dagger (P_{11} - i P_{12})^2 V_{11} \\
&= V_{21}^\dagger (P_{22} - i P_{21})^2 V_{21} \\
D &= -i V_{11}^\dagger V_{12} \\
&= i V_{21}^\dagger V_{22} .
\end{align*}
\]

The equality of the two expressions for \( C \), as well as the two expressions for \( D \), are demonstrated in the Appendix. One can verify that \( A A^\dagger = B B^\dagger = C C^\dagger = D D^\dagger = I \), such that \( A, B, C, \) and \( D \) are all unitary. For this purpose, it is necessary to observe that \( P_{11} \) and \( P_{12} \) commute, as well as \( P_{21} \) and \( P_{22} \) [19]. Finally, one may check that

\[
\begin{align*}
A(I + C) &= 2 U_{11} \\
B(I - C) &= 2 U_{21} \\
A(I - C) D &= 2 U_{12} \\
B(I + C) D &= 2 U_{22} ,
\end{align*}
\]

such that (2) is fulfilled.

It is noteworthy that there exist two formal expressions for \( C \) and \( D \). Whenever the polar decompositions are unique, the two expressions evaluate to the same matrices. However, if one \( U_{jk} \) happens to be singular, its polar decomposition is not unique. In this case, it is important to choose \( C \) and \( D \) consistently, i.e. to take the first or second expression for both \( C \) and \( D \) in eqn (5).
The reader will easily verify that the above expressions for the matrices \( A, B, C, \) and \( D, \) for \( n = 2, \) recover the former formulae for the scalars \( a, b, c, \) and \( d. \) Just like there are two different expansions in the case \( n = 2, \) there also exists a second decomposition in the case of arbitrary even \( n. \) It satisfies

\[
A = (P_{11} - i P_{12})V_{11} \\
B = (P_{21} + i P_{22})V_{21} \\
C = V_{11}^\dagger (P_{11} + i P_{12})^2 V_{11} \\
D = i V_{11}^\dagger V_{12} \\

A' = (Q_{21} - i Q_{22})W_{21}W_{11}^\dagger (Q_{11} - i Q_{12}) \\
B' = (Q_{11} + i Q_{12})W_{11} \\
C' = (Q_{11} - i Q_{12})W_{11} \\
D' = -i W_{11}^\dagger W_{12}
\]

and

\[
A' = (Q_{21} + i Q_{22})W_{21}W_{11}^\dagger (Q_{11} + i Q_{12}) \\
B' = (Q_{11} + i Q_{12})W_{11} \\
C' = (Q_{11} + i Q_{12})W_{11} \\
D' = i W_{11}^\dagger W_{12},
\]

respectively. Here, \( Q_{jk}W_{jk} \) are the polar decompositions of the four blocks \( u_{jk} \) constituting the matrix \( u = FUF. \)

### 6 Examples

As an example, we synthesize here the two-qubit circuit realizing the unitary transformation

\[
\frac{1}{\sqrt{12}} \begin{pmatrix}
8 & 0 & 4 + 8i & 0 \\
2 + i & 3 - 9i & -2i & -3 - 6i \\
1 - 7i & 6 & -6 + 2i & -3 + 3i \\
3 + 4i & 3 - 3i & 2 - 4i & 9i
\end{pmatrix}.
\]
We perform the algorithm of Section 5, applying Heron’s iterative method for constructing the four polar decompositions [22], although other algorithms can be used equally. Using ten iterations for each Heron decomposition, we thus obtain the following two numerical results:

\[
A = \begin{pmatrix}
0.67 + 0.72i & -0.19 + 0.03i \\
0.18 + 0.06i & 0.80 - 0.57i \\
\end{pmatrix}, \\
B = \begin{pmatrix}
-0.33 - 0.64i & 0.50 - 0.47i \\
0.69 + 0.00i & -0.20 - 0.70i \\
\end{pmatrix}, \\
C = \begin{pmatrix}
-0.04 - 0.95i & -0.01 - 0.30i \\
-0.07 + 0.29i & 0.25 - 0.92i \\
\end{pmatrix}, \quad \text{and} \quad D = \begin{pmatrix}
0.87 - 0.43i & -0.15 + 0.20i \\
-0.08 - 0.24i & -0.68 - 0.68i \\
\end{pmatrix},
\]

and

\[
A = \begin{pmatrix}
0.67 - 0.72i & 0.19 - 0.03i \\
0.16 + 0.10i & -0.30 - 0.93i \\
\end{pmatrix}, \\
B = \begin{pmatrix}
0.50 - 0.52i & 0.50 + 0.47i \\
-0.19 + 0.66i & 0.70 + 0.20i \\
\end{pmatrix}, \\
C = \begin{pmatrix}
-0.04 + 0.95i & -0.07 - 0.29i \\
-0.01 + 0.30i & 0.25 + 0.92i \\
\end{pmatrix}, \quad \text{and} \quad D = \begin{pmatrix}
-0.87 + 0.43i & 0.15 - 0.20i \\
0.08 + 0.24i & 0.68 + 0.68i \\
\end{pmatrix}.
\]

In contrast to the numerical approach in the first example, we will now perform an analytic decomposition of a second example:

\[
U = \begin{pmatrix}
1 & \cos(t) & \sin(t) \\
-\sin(t) & \cos(t) & 0 \\
0 & 0 & 1 \\
\end{pmatrix},
\]

i.e. a typical evolution matrix for spin-spin interaction, often discussed in physics. We have the following four matrix blocks and their polar decompositions:

\[
U_{11} = \begin{pmatrix} 1 & 0 \\ 0 & c \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ 0 & c \end{pmatrix} \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}
\]

\[
U_{12} = \begin{pmatrix} 0 & 0 \\ s & 0 \end{pmatrix} = \begin{pmatrix} 0 & 0 \\ 0 & s \end{pmatrix} \begin{pmatrix} 0 & y \\ 1 & 0 \end{pmatrix}
\]

\[
U_{21} = \begin{pmatrix} 0 & -s \\ 0 & 0 \end{pmatrix} = \begin{pmatrix} s & 0 \\ 0 & 0 \end{pmatrix} \begin{pmatrix} 0 & -1 \\ z & 0 \end{pmatrix}
\]

\[
U_{22} = \begin{pmatrix} c & 0 \\ 0 & 1 \end{pmatrix} = \begin{pmatrix} c & 0 \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}
\]

\[\text{In fact, the presented polar decompositions are only valid if } 0 \leq t \leq \pi/2 \text{ (i.e. if both } c \geq 0 \text{ and } s \geq 0). \text{ However, the reader can easily treat the three other cases.}\]
where \(c\) and \(s\) are short-hand notations for \(\cos(t)\) and \(\sin(t)\), respectively. Two blocks, i.e. \(U_{12}\) and \(U_{21}\), are singular and therefore have a polar decomposition which is not unique: both \(y\) and \(z\) are arbitrary numbers on the unit circle in the complex plane. By choosing consistently the ‘second expressions’ of \(C\) and \(D\), we find the following decompositions of \(U\):

\[
\begin{bmatrix}
1 & e \\
-iz & ie
\end{bmatrix} \frac{1}{2} \begin{bmatrix}
2 & 1 + 1/e^2 & 1 - 1/e^2 \\
1 - 1/e^2 & 2 & 1 + 1/e^2
\end{bmatrix} \begin{bmatrix}
1 & 1 \\
-i & -i/z
\end{bmatrix}
\]

and

\[
\begin{bmatrix}
1 & 1/e \\
iz & -i/e
\end{bmatrix} \frac{1}{2} \begin{bmatrix}
2 & 1 + e^2 & 1 - e^2 \\
1 - e^2 & 2 & 1 + e^2
\end{bmatrix} \begin{bmatrix}
1 & 1 \\
i & i/z
\end{bmatrix},
\]

where \(e\) is a short-hand notation for \(c + is\). In spite of the singular nature of both \(P_{12}\) and \(P_{21}\), this leaves only a 1-dimensional infinitum of decompositions. The fact that some matrices \(U\) have an infinity of decompositions is further discussed in next section.

As a third and final example, we consider for \(U\) a permutation matrix. Such choice is particularly interesting, as a \(2^w \times 2^w\) permutation matrix represents a classical reversible computation on \(w\) bits \([17, 23]\). For \(w = 2\), we investigate the example

\[
U = \begin{pmatrix}
0 & 1 & 0 & 0 \\
0 & 0 & 0 & 1 \\
1 & 0 & 0 & 0 \\
0 & 0 & 1 & 0
\end{pmatrix}.
\]

We have

\[
U_{11} = \begin{pmatrix}
0 & 1 \\
0 & 0
\end{pmatrix} = \begin{pmatrix}
1 & 0 \\
0 & 0
\end{pmatrix} \begin{pmatrix}
0 & 1 \\
x & 0
\end{pmatrix},
\]

\[
U_{12} = \begin{pmatrix}
0 & 0 \\
0 & 1
\end{pmatrix} = \begin{pmatrix}
0 & 0 \\
0 & 1
\end{pmatrix} \begin{pmatrix}
y & 0 \\
0 & 1
\end{pmatrix},
\]

\[
U_{21} = \begin{pmatrix}
1 & 0 \\
0 & 0
\end{pmatrix} = \begin{pmatrix}
1 & 0 \\
0 & 0
\end{pmatrix} \begin{pmatrix}
1 & 0 \\
z & 0
\end{pmatrix},
\]

\[
U_{22} = \begin{pmatrix}
0 & 0 \\
1 & 0
\end{pmatrix} = \begin{pmatrix}
0 & 0 \\
0 & 1
\end{pmatrix} \begin{pmatrix}
0 & w \\
1 & 0
\end{pmatrix}.
\]
where \( x, y, z, \) and \( w \) are arbitrary unit-modulus numbers. If, in particular, we choose \( x = w = -i \) and \( y = z = i \), then we find a decomposition of \( U \) consisting exclusively of permutation matrices:

\[
\begin{pmatrix}
0 & 1 \\
1 & 0 \\
1 & 0 \\
0 & 1
\end{pmatrix}
\begin{pmatrix}
0 & 1 \\
1 & 0 \\
0 & 1
\end{pmatrix}
\begin{pmatrix}
1 & 0 \\
0 & 1
\end{pmatrix}.
\]

In the next section, we will demonstrate that such is possible for any \( n \times n \) permutation matrix (provided \( n \) is even).

### 7 Light matrices and classical computing

The second and third example in previous section lead us to a deeper analysis of sparse unitary matrices.

**Definition:** Let \( M \) be an \( m \times m \) matrix with, in each line and each column, maximum one non-zero entry. We call such sparse matrix ‘light’. Let \( \mu \) be the number of non-zero entries of \( M \). We call \( \mu \) the weight of \( M \). We have \( 0 \leq \mu \leq m \). If \( \mu = m \), then \( M \) is regular; if \( \mu < m \), then \( M \) is singular. The reader will easily prove the following two lemmas:

**Lemma 1:** Let \( PU \) (with \( P \) a positive-semidefinite matrix and \( U \) a unitary matrix) be the polar decomposition of a light matrix \( M \). Then \( P \) is a diagonal matrix and \( U \) is a complex permutation matrix. If \( \mu \), the weight of \( M \), equals \( m \), then \( U \) is unique; otherwise, we have an \((m - \mu)\)-dimensional infinity of choices for \( U \).

**Lemma 2:** If \( P \) is a diagonal matrix and \( U \) is a complex permutation matrix, then \( U^\dagger PU \) is a diagonal matrix, with the same entries as \( P \), in a permuted order.

We now combine these two lemmas. Assume that the \( n \times n \) matrix \( U \) consists of four \( n/2 \times n/2 \) blocks, such that the two blocks \( U_{11} \) and \( U_{12} \) are light. Then, by virtue of Lemma 1, the positive-semidefinite matrices \( P_{11} \) and \( P_{12} \) are diagonal. Therefore \( P_{11} - iP_{12} \) is diagonal and so is \((P_{11} - iP_{12})^2\). By virtue of Lemma 1 again, the matrix \( V_{11} \) is a complex permutation matrix. Finally, because of Lemma 2, the matrix \( C = V_{11}^\dagger(P_{11} - iP_{12})^2V_{11} \) is diagonal and so are \( I + C \) and \( I - C \). As a result, for \( n = 2^w \), the matrix \( F\left(\begin{array}{c} i \\ c \end{array}\right)F = \frac{1}{2}\left(\begin{array}{cc} i + C & i - C \\ i - C & i + C \end{array}\right) \) represents a cascade of \( 2^{w-1} \) NEGATOR gates.
acting on the first qubit and controlled by the $w - 1$ other qubits:

$$
\begin{array}{c}
\text{H} \\
\text{diagonal } C \\
\text{H}
\end{array} =
\begin{array}{c}
\text{ } \\
\text{ } \\
\text{ }
\end{array}
$$

We now are in a position to discuss the case of $U$ being an $n \times n$ permutation matrix. Its special interest results from the fact that, for $n$ equal to a power of 2, such matrix represents a classical reversible computation.

First, we will prove that $\frac{1}{2} \left( \begin{smallmatrix} 1 & C \\ i & C \end{smallmatrix} \right)$ is a structured permutation matrix. If $U$ is an $n \times n$ permutation matrix, then both $n/2 \times n/2$ blocks $U_{11}$ and $U_{12}$ are light, the sum of their weights $\mu_{11}$ and $\mu_{12}$ being equal to $n/2$. The matrices $P_{11}$ and $P_{12}$ are diagonal, with entries equal to 0 or 1, with the special feature that, wherever there is a zero entry in $P_{11}$, the matrix $P_{12}$ has a 1 on the same row, and vice versa. The matrix $P_{11} - iP_{12}$ thus is diagonal, with all diagonal entries either equal to 1 or to $-1$. Hence, the matrix $\left( P_{11} - iP_{12} \right)^2$ is diagonal, with all diagonal entries either equal to 1 or to $-1$, and so is matrix $C$. Hence, the matrices $I + C$ and $I - C$ are diagonal with entries either 0 or 2. As a result, for $n = 2^w$, the matrix $F\left( \begin{smallmatrix} 1 & C \\ i & C \end{smallmatrix} \right) = \frac{1}{2} \left( \begin{smallmatrix} 1 & C \\ i & C \end{smallmatrix} \right)$ represents a cascade of 1-qubit IDENTITY and NOT gates acting on the first qubit and controlled by the $w - 1$ other qubits. Thus the above $2^{w-1}$ NEGATOR gates all equal a classical gate: either an IDENTITY gate or a NOT gate.

Next, we proceed with proving that $D$ is also a permutation matrix. The matrices $V_{11}$ and $V_{12}$ are complex permutation matrices. The matrix $V_{11}$ contains $n/2$ non-zero entries. Among them, $n/2 - \mu_{11}$ can be chosen arbitrarily, $\mu_{11}$ being the weight of $U_{11}$. We denote these arbitrary numbers by $x_j$, in analogy to $x$ in the third example of Section 6. Analogously, we denote by $y_k$ the $n/2 - \mu_{12}$ arbitrary entries of $V_{12}$. Because $U$ is a permutation matrix, the weight sum $\mu_{11} + \mu_{12}$ necessarily equals $n/2$. The matrix $-iV_{11}^\dagger V_{12}$ also is a complex permutation matrix and thus has $n/2$ non-zero entries. The number matches the total number of degrees of freedom $(n/2 - \mu_{11}) + (n/2 - \mu_{12}) = n/2$. Because $U$ is a permutation matrix, $V_{11}$ and $V_{12}$ can be chosen such that the non-zero entries of the product $-iV_{11}^\dagger V_{12}$ depend only on an $x_j$ or on an $y_k$ but not on both. More particularly these entries are either of the form $-i/x_j$ or of the form $-iy_k$. By choosing all $x_j$ equal to $-i$ and all $y_k$ equal to $i$, the matrix $-iV_{11}^\dagger V_{12}$, and thus $D$, is a permutation matrix.
Because $U$, $\frac{1}{2} \begin{pmatrix} I + C & I - C \\ I - C & I + C \end{pmatrix}$, and $\begin{pmatrix} A & B \\ C & D \end{pmatrix}$ are permutation matrices, also $\begin{pmatrix} A & B \\ C & D \end{pmatrix}$ is an $n \times n$ permutation matrix. Ergo: given an $n \times n$ permutation matrix $U$, we can construct four $n/2 \times n/2$ permutation matrices $A$, $B$, $C$, and $D$. Therefore, we recover here the Birkhoff decomposition method for permutation matrices and thus, for $n = 2^w$, a well-known synthesis method for classical reversible logic circuits [17, 24, 25], based on the Young subgroups of the symmetric group $S_{2^w}$.

8 Conclusion

Thanks to the Führ and Rzeszotnik decomposition of $U(n)$ matrices with even $n$, and three more decompositions presented above, we can synthesize the quantum circuit performing an arbitrary unitary transformation from $U(2^w)$, in four systematic and straightforward ways. The present $bZbXbZ$ and $bXbZbX$ decompositions are more practical than the $ZXZ$ decomposition because no Fourier transforms $F_j$ (with $2 \leq j \leq 2^w$) are necessary. Only controlled $XU(2)$ or $\text{NEGATOR}$s and controlled $ZU(2)$ or $\text{PHASOR}$s are necessary. Alternatively, one can apply controlled $\text{PHASOR}$s combined with controlled Hadamard gates, i.e. $F_2$ transforms.

In contrast to previously developed synthesis methods for quantum circuits (based e.g. on the sine-cosine or the KAK or the Householder decomposition), the present four matrix decompositions naturally include the synthesis of classical reversible circuits.

Appendix

Lemma 3: Let $P$ and $P'$ be positive-semidefinite matrices, let $U$ and $U'$ be unitary matrices, and let $PU = P'U'$. Then, $U$ is equal to $U'$, provided $P$ and $P'$ are regular.

Lemma 4: Let $P_j$ and $U_j$ be positive-semidefinite and unitary matrices, respectively. Then any equality of the form $P_1U_1P_2U_2P_3U_3... = P'_1U'_1P'_2U'_2P'_3U'_3...$ implies $U_1U_2U_3... = U'_1U'_2U'_3...$, provided all $P_j$ and all $P'_j$ are regular. The proof is based on repeated application of $PU = UQ$.
with $Q = U^\dagger PU$ also a positive-semidefinite matrix, followed by use of Lemma 3. ■

From the unitarity condition $U^\dagger U = UU^\dagger = \begin{pmatrix} I & 0 \\ 0 & I \end{pmatrix}$ follows:

\[ P_{11}^2 + P_{12}^2 = I \]
\[ P_{21}^2 + P_{22}^2 = I \]
\[ V_{11}^\dagger P_{11}^2 V_{11} + V_{21}^\dagger P_{21}^2 V_{21} = I \]
\[ V_{12}^\dagger P_{12}^2 V_{12} + V_{22}^\dagger P_{22}^2 V_{22} = I , \] (6)

as well as

\[ P_{11} V_{11} V_{21}^\dagger P_{21} + P_{12} V_{12} V_{22}^\dagger P_{22} = 0 \]
\[ V_{11}^\dagger P_{11} P_{12} V_{12} + V_{21}^\dagger P_{21} P_{22} V_{22} = 0 . \] (8)

If $P_{11}$, $P_{12}$, $P_{21}$, and $P_{22}$ are regular, then, by virtue of Lemma 4, this leads to

\[ V_{11} V_{21}^\dagger = -V_{12} V_{22}^\dagger \] (9)
\[ V_{11}^\dagger V_{12} = -V_{21}^\dagger V_{22} . \] (10)

In the expression

\[ V_{11}^\dagger (P_{11} - i P_{12})^2 V_{11} \]

or

\[ V_{11}^\dagger P_{11}^2 V_{11} - i V_{11}^\dagger P_{11} P_{12} V_{11} - i V_{11}^\dagger P_{12} P_{11} V_{11} - V_{11}^\dagger P_{12}^2 V_{11} , \]

we eliminate $P_{11}^2$ with the help of (6), $P_{11} P_{12}$ with the help of (8), $P_{12} P_{11}$ with the help of (5), $P_{12}^2$ with the help of (7). Subsequently, we eliminate $V_{11}$ and $V_{11}^\dagger$ with the help of (9-10). We thus obtain

\[ V_{21}^\dagger P_{22}^2 V_{21} - i V_{21}^\dagger P_{21} P_{22} V_{21} - i V_{21}^\dagger P_{22}^2 V_{21} - V_{21}^\dagger P_{22}^2 V_{21} = V_{21}^\dagger (P_{22} - i P_{21})^2 V_{21} . \]
