A MAJOR GENETIC LOCUS AFFECTING RESISTANCE TO INFECTION WITH MURINE LEUKEMIA VIRUSES

III. ASSIGNMENT OF THE \textit{Fv-1} LOCUS TO LINKAGE GROUP VIII OF THE MOUSE

BY WALLACE P. ROWE, JAMES B. HUMPHREY, AND FRANK LILLY

\textit{(From the Laboratory of Viral Diseases, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, Maryland 20014, and the Department of Genetics, Albert Einstein College of Medicine, Bronx, New York 10461)}

(Received for publication 18 December 1972)

The \textit{Fv-1} locus of the mouse (1) has been shown to play a major role in the biology of murine leukemia virus (MLV) infection both in vivo and in vitro by determining the sensitivity or resistance of the cells to exogenous infection by the various host-range types of MLV. \textit{Fv-1} type markedly affects the magnitude of response of mice to infection with Friend virus (1) or pseudotypes of murine sarcoma virus (2), the plaquing efficiency of naturally occurring MLV strains when grown in tissue culture (3, 4), and the degree of spread of endogenous, genetically acquired MLV in hybrids between low virus mouse strains and the high virus strain AKR (5, 6). In addition, \textit{Fv-1} appears to have a marked effect on the incidence of spontaneous lymphomas in \(F_1\) hybrids between AKR and low leukemic mouse strains (6).

Two alleles of \textit{Fv-1} have been defined. \textit{Fv-1} \textit{a} mice and their cells in tissue culture are sensitive to infection with N-tropic MLV strains (2) and are relatively resistant to B-tropic strains; \textit{Fv-1} \textit{b} mice show the reciprocal pattern. Heterozygotes, \textit{Fv-1} \textit{ab}, are resistant to both N- and B-tropic strains.

In this report we present evidence that the \textit{Fv-1} locus is on linkage group VIII, about 39 map units from \(b\), the locus for brown or black hair color.

In studies of the genetic transmission of the naturally occurring N-tropic MLV infection of AKR mice (5, 6), which are \textit{Fv-1} \textit{a}, crosses were made between \textit{Fv-1} \textit{a} and \((F_{v-P} \times \text{AKR})F_1\) mice, and the progeny were \textit{Fv-1} typed by the spleen focus assay for susceptibility to Friend virus (7). In an extension of these studies, a larger number of C57BR \(\times\) (BALB/c \(\times\) AKR)\(F_1\), i.e. BR \(\times\) (C \(\times\) AK)\(F_1\), mice have been \textit{Fv-1} typed, and a correlation between \textit{Fv-1} type and black or brown coat color was observed. This coloration is determined by the \(b\) locus on linkage group VIII, at which the wild type, black (\textit{B}), is dominant to brown (\textit{b}). BALB/c (\textit{Fv-1b}) carries the \(b\) allele, and AKR the \(B\)
allele; a cross of (C × AK)F₁ mice with C57BR (Fv-I⁺, b) gives equal numbers of black (B/b) and brown (b/b) progeny. The association of Fv-I type with coat color is shown in Table I, line 1. The correlation was highly significant (χ² with 1 degree of freedom = 11.7, P < 0.001), indicating that the two genes are linked. The BR × (C × AK)F₁ cross also segregates for a (agouti); there was no association of this marker with Fv-I.

In crosses with low virus mouse strains, the AKR mouse contributes two unlinked chromosomal loci, either of which results in presence of infectious N-tropic MLV by 2–6 wk of age in Fv-I⁻ progeny (5, 6); thus, in an Fv-I⁻ × (Fv-I⁻ × AKR)F₁ backcross, 75% of the mice are virus positive. In Fv-Iⁿ mice, either in the F1 or segregating generations, detection of virus is less frequent, since titers are suppressed by the inefficient spread of virus from spon-

| Cross | no. of Fv-I⁺ mice/no. in category | Color marker from Fv-I⁺ grandparent | Color marker from Fv-I⁻ grandparent | Total | Recombinational frequency ± standard error |
|-------|----------------------------------|-----------------------------------|-----------------------------------|-------|------------------------------------------|
| C57BR × (BALB/c × AKR)F₁ | 54/85 64 27/79 34 81/164 49 | 35 ± 3.1 |
| (C57BL/6 × DBA/2)F₁ × DBA/2* | 34/60 57 27/76 36 61/136 45 | 39 ± 4.2 |

* Mice that were positive for virus at either 2 or 8 wk are considered positive mice.

**P** value determined by comparing the proportions positive for virus. Chi-square test with 1 degree of freedom.

 correlate with coat color, but there is no such correlation in crosses involving only Fv-1^a^ strains.

A possible objection to the above-described studies is that the Fv-1 typing results might have been biased by the endogenous MLV infection. On the one hand, the endogenous virus might conceivably act as a helper virus (8), which could increase the spleen focus response to Friend virus and result in a mouse of Fv-1^a^ genotype being classified as Fv-1^b_. On the other hand, the endogenous infection might produce some protection, resulting in fewer spleen foci and classification of an Fv-1^a_ mouse as Fv-1^b_. To obviate these difficulties, two crosses between mice of low virus strains were examined for linkage between Fv-1 and b (Table I, lines 2 and 3). There was again correlation between the two markers; for the two groups combined, \( \chi^2 = 5.6, P = 0.02 \).

Analysis of the literature on incidence of spontaneous leukemia in hybrids between AKR and low leukemia strains suggests that the Fv-1 type of the latter is a major determinant (6). This is compatible with the concept that cell-to-cell spread of virus is important in the pathogenesis of this disease. In attempting to determine whether other types of tumors are caused by endogenous MLV infection, which might be by presently unknown host-range types and affected by unrecognized Fv-1 subtypes, segregation analysis of tumor occurrence in relation to inheritance of the Fv-1 locus could be useful, particularly if a closely linked marker can be found.

A preliminary finding suggests that Fv-1 may be close to the Gpd-1 locus, which is on linkage group VIII about 32 map units from b (9). Axelrad et al.
(10) have produced a line (SIM.R) congenic with SIM mice (Fe-1ª), but carrying the Fe-1ª allele from C57BL/6; these mice were inbred after the eighth backcross generation to SIM. We have found that in addition to the Fe-1 locus, SIM.R carries the Gpd-1ª allele from C57BL, the SIM strain being Gpd-1.

**SUMMARY**

The Fe-1 gene, which regulates sensitivity of mouse cells to infection by naturally occurring host-range types of murine leukemia virus, was shown to be located on linkage group VIII (chromosome 4), 39 map units from b.

This work was supported in part by the Special Virus Leukemia Program of the National Cancer Institute. We are indebted to Dr. Arthur Axelrad for supplying the SIM and SIM.R mice, and to Dr. Theodore Bremner for the Gpd-1 testing.
