FINITENESS OF RANK FOR GRASSMANN CONVEXITY

NICOLAU C. SALDANHA, BORIS SHAPIRO, AND MICHAEL SHAPIRO

Abstract. The Grassmann convexity conjecture, formulated in [8], gives a conjectural formula for the maximal total number of real zeros of the consecutive Wronskians of an arbitrary fundamental solution to a disconjugate linear ordinary differential equation with real time. The conjecture can be reformulated in terms of convex curves in the nilpotent lower triangular group. The formula has already been shown to be a correct lower bound and to give a correct upper bound in several small dimensional cases. In this paper we obtain a general explicit upper bound.

1. Introduction

A linear homogeneous differential equation of order $n$ with continuous real coefficients defined on some open interval $I$ of the real axis is called disconjugate on $I$ (see [2, 6]) if any of its nonzero solutions has at most $n - 1$ real zeros on $I$, counting multiplicities. Any such differential equation is disconjugate on a sufficiently small interval $I ⊂ \mathbb{R}$.

The Grassmann convexity conjecture, formulated in [8], says that, for any positive integer $k$ satisfying $0 < k < n$, the number of real zeros in $I$ of the Wronskian of any $k$ linearly independent solutions to a disconjugate differential equation of order $n$ on $I$ is bounded from above by $k(n - k)$, which is the dimension of the Grassmannian $G(k, n; \mathbb{R})$. This conjecture can be reformulated in terms of convex curves in the nilpotent lower triangular group (see Section 2 and also [3, 5, 4]). The number $k(n - k)$ has already been shown to be a correct lower bound for all $k$ and $n$. Moreover it gives a correct upper bound for the case $k = 2$ (see [7]). In this paper we obtain a general explicit upper bound for the above maximal total number of real zeros which, although weaker than the one provided by the Grassmann convexity conjecture, still gives an interesting information.

We now formulate a discrete problem which is equivalent to the above Grassmann convexity conjecture; the equivalence is discussed in Section 2. The statement and proof of our main theorem are self-contained and elementary.

Given integers $k$ and $n$ with $0 < k < n$, consider a collection $(v_j)_{1 \leq j \leq n}$ of vectors in $\mathbb{R}^k$, or, equivalently, a matrix $M \in \mathbb{C} = \mathbb{R}^{k \times n}$. Set $v_j = Me_j$, so that $v_j$ is the $j$-th column of $M$. For two matrices $M_0, M_1 \in \mathcal{C}$, we say that there exists a positive elementary move from $M_0$ to $M_1$ if there exists $j < n$ and $t \in (0, +\infty)$ such that $M_1e_j = M_0e_j + tM_0e_{j+1}$ and $M_1e_{j'} = M_0e_{j'}$ for $j' \neq j$. In other words, the vector $v_j$ moves towards $v_{j+1}$ and the other vectors remain constant. We call a sequence $(M_s)_{0 \leq s \leq \ell}$ of $k \times n$-matrices convex if, for all $s < \ell$, there exists a
positive elementary move from $M_s$ to $M_{s+1}$. The terminology is motivated by their relationship with convex curves in the lower triangular group $\text{Lo}_1^n$; see Section 2 and [7].

For $J = \{j_1 < \cdots < j_k\} \subset \{1, \ldots, n\}$, define the function $m_J : C \to \mathbb{R}$ by

$$(1) \quad m_J(M) = \det(\text{SubMatrix}(M, \{1, \ldots, k\}, J)) = \det(v_{j_1}, \ldots, v_{j_k}).$$

We are particularly interested in $m_\bullet = m_{\{1, \ldots, k\}}$. Define an open dense subset of $(k \times n)$-matrices $C^* = \bigcap_{J \subset \{1, \ldots, n\}, |J| = k} m_J^{-1}([\mathbb{R} \setminus \{0\}] \subset C$.

For convex sequences $M = (M_s)_{0 \leq s \leq \ell}$ of matrices in $C^*$, we are interested in the number of sign changes of $m$:

$$nsc(M) = |\{s \in [0, \ell] \cap \mathbb{Z} | m_\bullet(M_s)m_\bullet(M_{s+1}) < 0\}|.$$

(Notice that $M$ is merely a sequence of matrices, not an actual path of matrices; equivalently, $s$ assumes integer values only.)

The Grassmann convexity conjecture, in the discrete model, states that for every convex sequence $M$ we have:

$$(2) \quad nsc(M) \leq k(n - k).$$

The equivalence between formulations is discussed in Section 2. The case $k = 1$ is easy; the case $k = 2$ is settled in [7]; in the same paper we prove that for all $k$ and $n$, there exists a convex sequence $M$ with $nsc(M) = k(n - k)$. In this paper we prove the following estimate.

**Theorem 1.** For any $2 < k < n$ and any convex sequence of matrices $M$, we have

$$(3) \quad nsc(M) < \frac{(n - k + 1)^{2k-3}}{2^{k-3}}.$$

Inequality (3) appears to be the first known explicit upper bound for $nsc(M)$ in terms of $k$ and $n$. This bound is a polynomial in $n$ of degree $2k-3$. Furthermore, by a well-known (Grassmann) duality interchanging $k \leftrightarrow (n - k)$, one can additionally obtain

$$nsc(M) < \min \left(2^{3-k}(n - k + 1)^{2k-3}, 2^{3-n+k}(k + 1)^{2(n-k)-3}\right).$$

We know however that the bound in Theorem 1 is not sharp; see Remark 4.2. Our current best guess is that the Grassmann convexity conjecture indeed holds for all $0 < k < n$; this is additionally supported by our recent computer-aided verification of the latter conjecture in case $k = 3$, $n = 6$.

2. Discrete and continuous versions

In this section we present an alternative continuous version of the Grassmann convexity conjecture already discussed in previous papers and prove that it is equivalent to the discrete version described in the introduction. We follow the notations of [5] and [7].

Consider the nilpotent Lie group of $\text{Lo}_1^n$ of real lower triangular matrices with diagonal entries equal to 1. Its corresponding Lie algebra is $\mathfrak{lo}_1^n$, the space of strictly lower triangular matrices. For $J \subset \{1, \ldots, n\}$, $|J| = k$, define $m_J : \text{Lo}_1^n \to \mathbb{R}$ as in Equation (1); thus, $m_\bullet(L) = m_{\{1, \ldots, k\}}(L)$ is the determinant of the lower-left $k \times k$
minor of $L$. For $1 \leq j < n$, let $t_j = e_{j+1}e_j^T \in \mathbb{L}_n^1$ be the matrix with only one nonzero entry $(t_j)_{j+1,j} = 1$. Write $\lambda_j(t) = \exp(t_j)$.

A smooth curve $\Gamma : [a, b] \to \mathbb{L}_n^1$ is convex if there exist smooth positive functions $\beta_j : [a, b] \to (0, +\infty)$ such that, for all $t \in [a, b]$,

$$(\Gamma(t))^{-1} \Gamma'(t) = \sum_j \beta_j(t) t_j.$$  

We prove in [5] that all zeroes of $m_{\bullet} \circ \Gamma : [a, b] \to \mathbb{R}$ are isolated (and of finite multiplicity). Let $nz(\Gamma)$ be the number of zeroes of $m_{\bullet} \circ \Gamma$ counted without multiplicity. The Grassmann convexity conjecture states that $nz(\Gamma) \leq \ell$.

(In fact, following the ideas presented in the proof of Theorem 2 of [7], one can show that the maximal numbers of zeros of $m_{\bullet} \circ \Gamma$ counted with and without multiplicity actually coincide.)

Let $S_n$ be the symmetric group with the standard generators $a_j = (j, j+1), 1 \leq j < n$. Let $\eta \in S_n$ be the permutation with the longest reduced word; its length equals $m = n(n-1)/2$. Let $\text{Pos}_\eta \subset \mathbb{L}_n^1$ be the semigroup of totally positive matrices, an open subset (see [1, 5]). The boundary of $\text{Pos}_\eta$ can be stratified as

$$\partial \text{Pos}_\eta = \bigsqcup_{\sigma \in S_n, \sigma \neq \eta} \text{Pos}_\sigma$$

(we follow the notation of [5]; the subsets $\text{Pos}_\sigma \subset \mathbb{L}_n^1$ and the above stratification are discussed in Section 5). Let $\sigma = a_{i_1}\cdots a_{i_t}$ be a reduced word: if $L \in \text{Pos}_\sigma$ then there exist unique positive $t_1, \ldots, t_l$ such that $L = \lambda_{i_1}(t_1)\cdots \lambda_{i_l}(t_l)$. Conversely, if $t_1, \ldots, t_l > 0$ then $\lambda_{i_1}(t_1)\cdots \lambda_{i_l}(t_l) \in \text{Pos}_\sigma$. If $\Gamma$ is convex and $t_0 < t_1$ then $(\Gamma(t_0))^{-1} \Gamma(t_1) \in \text{Pos}_\eta$. Conversely, if $L_0^{-1}L_1 \in \text{Pos}_\eta$ then there exists a convex curve $\Gamma : [0, 1] \to \mathbb{L}_n^1$ with $\Gamma(0) = L_0$ and $\Gamma(1) = L_1$ (see [5], Lemma 5.7).

**Lemma 2.1.** Fix $k, n, r \in \mathbb{N}$, with $0 < k < n$. If $nsc(M) \leq r$ for every convex sequence $M = (M_s)_{0\leq s \leq \ell}$, then $nz(\Gamma) \leq r$ for every convex curve $\Gamma$. Conversely, if $nz(\Gamma) \leq r$ for every convex curve $\Gamma$ then $nsc(M) \leq r$ for every convex sequence $M = (M_s)_{0\leq s \leq \ell}$.

**Proof.** Consider a convex curve $\Gamma_0$ with $nz(\Gamma_0) = r$. We use $\Gamma_0$ to construct a convex sequence $M$ with $nsc(M) \geq r$. Indeed, let $t_1 < \cdots < t_r$ be such that $n_{\Gamma_0}(\Gamma(s)) = 0$ for all $1 \leq s \leq r$. Take $M_s = \text{SubMatrix}(\Gamma(s), \{n-k+1, \ldots, n\}, \{1, \ldots, n\})$ and corresponding vectors $\tilde{v}_{s,j}$. By taking a small perturbation we may assume that $m_{\bullet}(M_s) \neq 0$ for $|J| = k, J \neq \{1, \ldots, k\}$. For $m = n(n-1)/2$ and a small positive number $\epsilon > 0$, set $M_{(m+1)s} := M_s \lambda_k(-\epsilon), M_{(m+1)s+1} := M_s \lambda_k(\epsilon)$. Notice that there exists a positive elementary move from $M_{(m+1)s}$ to $M_{(m+1)s+1}$ and that $\text{sign}(m_{\bullet}(M_{(m+1)s+1})) \neq \text{sign}(m_{\bullet}(M_{(m+1)s}))$. If the above perturbation and $\epsilon > 0$ are sufficiently small, there exists $L_s \in \text{Pos}_\eta$ such that $M_{(m+1)s+1} = M_{(m+1)s+1} L_s$. Write $L_s = \lambda_{i_1}(t_1)\cdots \lambda_{i_m}(t_m)$ and, for $1 \leq j \leq m$, recursively define $M_{(m+1)s+j+1} = M_{(m+1)s+j} \lambda_{i_j}(t_j)$. This is the desired convex sequence of matrices.

Conversely, let $M = (M_s)_{0\leq s \leq \ell}$ be a convex sequence of matrices with $nsc(M) = r$. We use $M$ to construct a smooth convex curve $\Gamma$ with $nz(\Gamma) \geq r$. For each $s$, we have $M_{s+1} = M_s \lambda_{i_s}(t_s), t_s > 0$. Notice that $\lambda_{i_s}(t_s) \in \text{Pos}_{\eta_s}$. If needed slightly perturb the matrices $(M_s)$ to obtain matrices $(M_s)$ such that $M_{s+1} = M_s L_s, L_s \in \text{Pos}_\eta$. Define $\Gamma(1) \in \mathbb{L}_n^1$ such that $M_1 = \text{SubMatrix}(\Gamma(1), \{n-k+1, \ldots, n\})$.
Recursively define $\Gamma(s + 1) = \Gamma(s)L_s$ so that for all $s \in \mathbb{Z}$, $1 \leq s \leq \ell$, we have $M_s = \text{SubMatrix}(\Gamma(s), \{n-k+1, \ldots, n\}, \{1, \ldots, n\})$. Notice that for each $s$, there exists a smooth convex arc from $\Gamma(s)$ to $\Gamma(s + 1)$. As discussed in Section 6 of [4], these arcs can be chosen so that $\Gamma$ is also smooth at the integer glueing points. \hfill \square

3. Ranks

For $0 < k < n$, define $r(k, n) \in \mathbb{N} \cup \{\infty\} = \{0, 1, 2, \ldots, \infty\}$ as

$$r(k, n) = \sup_M \text{nsc}(M);$$

where $M$ runs over all convex sequences of matrices. By the main results of [7], $r(2, n) = 2(n - 2)$; and, additionally for all $0 < k < n$, we have $r(k, n) \geq k(n - k)$.

Using the examples for which $\text{nsc}(M) = k(n - k)$ provided by [7], the Grassmann convexity conjecture (as in Equation (2)) is equivalent to

$$r(k, n) = k(n - k).$$

Given a subset of $k \times n$-matrices $X \subseteq \mathbb{C}^*$, a prerank function for $X$ is a function $\text{pr} : X \rightarrow \mathbb{N} = \{0, 1, 2, \ldots\}$

with the properties:

1. if there exists a positive elementary move from $M_0 \in X$ to $M_1 \in X$ then $\text{pr}(M_0) \geq \text{pr}(M_1)$;
2. if there exists a positive elementary move from $M_0 \in X$ to $M_1 \in X$ and $m(M_0)m(M_1) < 0$ then $\text{pr}(M_0) > \text{pr}(M_1)$.

When $X$ is not mentioned we assume that $X = \mathbb{C}^*$. A prerank function for a convex sequence $M$ is, by definition, a prerank function for its image. A prerank function $\text{pr}$ for $\mathbb{C}^*$ is called regular if $\text{pr}(MD) = \text{pr}(M)$ for every $M \in \mathbb{C}^*$ and every positive diagonal matrix $D \in \mathbb{R}^{n \times n}$; in terms of sequences of vectors, this means that multiplying each vector $v_j$ by a positive real number $d_j$ does not affect the rank. For $k = 2$, a regular prerank function $\text{pr} : \mathbb{C}^* \rightarrow [0, 2(n - 2)] \cap \mathbb{N}$ has been constructed in [7].

Lemma 3.1. For $0 < k < n$, the following properties are equivalent:

1. $r(k, n) \leq r_0$;
2. there exists a regular prerank function for $\mathbb{C}^*$ whose image is contained in $[0, r_0]$;
3. there exists a prerank function for $\mathbb{C}^*$ whose image is contained in $[0, r_0]$;
4. for every convex sequence $M$ of matrices, there exists a prerank function for $M$ whose image is contained in $[0, r_0]$.

Proof. Assuming the first item, let us construct a regular prerank function. For $M \in \mathbb{C}^*$, set

$$\text{pr}(M) = \max_{M = (M_s)_{0 \leq s \leq \ell}, M_0 = M} \text{nsc}(M).$$

Regularity follows from the observation that if $D \in \mathbb{R}^{n \times n}$ is a positive diagonal matrix and $(M_s)$ is a convex sequence then so is $(M_sD)$. The second item trivially implies the third. Assuming the third item, we obtain a prerank function for $\mathbb{C}^*$. To
prove the fourth item, given a convex sequence, restrict the above prerank function to the image of $M$ to obtain a prerank function for $M$.

Given a convex sequence $M = (M_s)_{0 \leq s \leq \ell}$ and a prerank sequence for $\ell$, we obtain that $\text{nsc}(M) \leq \text{pr}(M_0) - \text{pr}(M_{\ell})$. Thus, the fourth item implies the first, completing the proof. □

4. Step lemma

The following lemma provides the induction step necessary to settle Theorem 4.

Lemma 4.1. For all $2 < k < n$, we have that

$$r(k, n) \leq \frac{(n-k+1)^2}{2} r(k-1, n-1).$$

Proof of Theorem 4. In order to use induction on $k$, notice first that the inequality (4) holds for $k = 2$. By inductive assumption and Lemma 4.1, we get

$$\text{nsc}(M) \leq r(k, n) \leq \frac{(n-k+1)^2}{2} r(k-1, n-1) < \frac{(n-k+1)^2}{2} 2^{3-(k-1)}(n-k+1)^{2k-3} = 2^{3-k}(n-k+1)^{2k-3},$$

completing the proof. □

Proof of Lemma 4.1. Set $r_- = r(k-1, n-1)$ (assumed to be finite) and define $r_0 := (n-k+1)^2 r_- / 2$. Let $C^* \subset C_- = R^{(k-1) \times (n-1)}$ be the set of matrices $M \in C_-$ with $m_j(M) \neq 0$ for all $J \subset \{1, \ldots, n-1\}$, $|J| = k-1$. By Lemma 3.1, there exists a regular prerank function $\text{pr}_- : C_- \rightarrow [0, r_-] \cap \mathbb{N}$. Given a convex sequence $M = (M_s)_{0 \leq s \leq \ell}$ of matrices in $C^* \subset C = R^{k \times n}$, we construct a prerank function for $M$ with image contained in $[0, r_0]$ by Lemma 3.1; this will complete the proof of Lemma 4.1.

Define $v_{s,j} = M_se_j$. Let $H_0 \subset R^k$ be a linear hyperplane in generic position, defined by a linear form $\omega : R^k \rightarrow R$; fix a basis of $H_0$ in order to identify it with $R^{k-1}$. Let $H_1 = \omega^{-1}\{\{1\}\}$ be an affine hyperplane parallel to $H_0$. We may assume that for all $s$ and $j$, we have $\omega(v_{s,j}) \neq 0$. We may furthermore assume that $\omega(v_{s,j}) > 0$ for $j > n-k$, which implies $\omega(v_{s,j}) > 0$ for $j > n-k$ and all $s$. Set $\tilde{v}_{s,j} = v_{s,j} / \omega(v_{s,j})$ so that $\tilde{v}_{s,j} \in H_1$. For $j < n$, set $w_{s,j} = \omega(v_{s,j+1})(\tilde{v}_{s,j+1} - \tilde{v}_{s,j}) \in H_0$. For a given $s$, the sequence of vectors $(w_{s,j})_{1 \leq j \leq n-1}$ defines a matrix $M_s \in C_- = R^{(k-1) \times (n-1)}$. We assume that $m(M_s) \neq 0$, which implies $m(M_s) \neq 0$.

Define the prerank as $\text{pr}(M_s) = \text{pr}_I(M_s) + \text{pr}_{II}(M_s) \cdot r_-,$ where

$$\text{pr}_I(M_s) = \text{pr}_-(M_s), \quad \text{pr}_{II}(M_s) = \sum_{1 \leq j < n} [\omega(v_{s,j}) \omega(v_{s,j+1}) < 0] \cdot j.$$ 

Here we use Iverson notation: $[\omega(v_{s,j}) \omega(v_{s,j+1}) < 0]$ equals 1 if $\omega(v_{s,j}) \omega(v_{s,j+1}) < 0$ and 0 otherwise. In particular, if $j > n-k$ then $[\omega(v_{s,j}) \omega(v_{s,j+1}) < 0] = 0$. We therefore have

$$\text{pr}_I(M_s) \in [0, r_-] \cap \mathbb{Z}, \quad \text{pr}_{II}(M_s) \in \left[0, \frac{(n-k+1)(n-k)}{2}\right] \cap \mathbb{Z},$$

and thus

$$\text{pr}(M_s) \in [0, r_0] \cap \mathbb{Z}.$$
We need to verify that $\text{pr}(M_s)$ is indeed a prerank function.

Recall that there exists a positive elementary move from $M_s$ to $M_{s+1}$, which we call the $s$-th move in $\mathbf{M}$. There are two kinds of positive elementary moves. If $\text{sign}(\omega(v_{s,j})) = \text{sign}(\omega(v_{s,j+1}))$ for all $j$ then we say the $s$-th move is of type I; otherwise it is of type II.

First consider $s$ of type II. Let $j$ be such that $v_{s+1,j} = v_{s,j} + tv_{s,j+1}, t > 0$. By taking $H$ in general position and introducing, if necessary, intermediate points we may assume that $\text{sign}(m(M_s)) = \text{sign}(m(M_{s+1}))$. For $j' \neq j$, we have $v_{s+1,j'} = v_{s,j'}$ implying that $\text{sign}(\omega(v_{s+1,j'})) = \text{sign}(\omega(v_{s,j'}))$. Therefore we have

$$\text{sign}(\omega(v_{s+1,j})) = \text{sign}(\omega(v_{s+1,j+1})) = \text{sign}(\omega(v_{s,j+1})) = -\text{sign}(\omega(v_{s,j}))$$

and thus

$$[\omega(v_{s,j})\omega(v_{s,j+1}) < 0] = 1, \quad [\omega(v_{s+1,j})\omega(v_{s+1,j+1}) < 0] = 0.$$

For $j' = j - 1$, we get

$$[\omega(v_{s,j})\omega(v_{s,j'+1}) < 0] = 1 - [\omega(v_{s+1,j'})\omega(v_{s+1,j'+1}) < 0];$$

while for $j' \notin \{j - 1, j\}$, we get

$$[\omega(v_{s,j'})\omega(v_{s,j'+1}) < 0] = [\omega(v_{s+1,j'})\omega(v_{s+1,j'+1}) < 0].$$

Thus, in all cases we obtain that $\text{pr}_{II}(M_{s+1}) < \text{pr}_{II}(M_s)$ which implies that $\text{pr}(M_{s+1}) \leq \text{pr}(M_s)$ independently of the values of $\text{pr}_{II}(M_s)$ and $\text{pr}_{II}(M_{s+1})$.

Consider now $s$ of type I so that $\text{pr}_{II}(M_s) = \text{pr}_{II}(M_{s+1})$. Again, let $j$ be such that $v_{s+1,j} = v_{s,j} + tv_{s,j+1}, t > 0$. For $j' \neq j$, we obtain $v_{s+1,j'} = v_{s,j'}$ and therefore $\tilde{v}_{s+1,j'} = \tilde{v}_{s,j'}$. Thus

$$\tilde{v}_{s+1,j} = \frac{\omega(v_{s,j})}{\omega(v_{s+1,j})}\tilde{v}_{s,j} + \frac{t\omega(v_{s,j+1})}{\omega(v_{s+1,j})}\tilde{v}_{s,j+1}, \quad \frac{\omega(v_{s,j})}{\omega(v_{s+1,j})} > 0;$$

implying that $\tilde{v}_{s+1,j}$ is an affine combination of $\tilde{v}_{s,j}$ and $\tilde{v}_{s,j+1}$. For $j' \notin \{j - 1, j\}$, we get that $w_{s+1,j'} = w_{s,j'}$. Finally, notice that $w_{s+1,j}$ is a positive multiple of $w_{s,j}$ and $w_{s+1,j-1}$ is a positive linear combination of $w_{s,j-1}$ and $w_{s,j}$. Namely,

$$w_{s+1,j} = \frac{\omega(v_{s,j})}{\omega(v_{s+1,j})}w_{s,j}, \quad w_{s+1,j-1} = \frac{\omega(v_{s+1,j})}{\omega(v_{s,j})}w_{s,j-1} + tw_{s,j}.$$ 

Therefore, up to multiplication by a positive diagonal matrix, the move from $\tilde{M}_s$ to $\tilde{M}_{s+1}$ is a positive elementary move. Thus $\text{pr}_-(M_{s+1}) \leq \text{pr}_-(M_s)$, or, equivalently, $\text{pr}_I(M_{s+1}) \leq \text{pr}_I(M_s)$. Finally, notice that the inequality $m(M_s)m(M_{s+1}) < 0$ implies that $m(M_s)m(M_{s+1}) < 0$ and therefore $\text{pr}_I(M_{s+1}) < \text{pr}_I(M_s)$. □

**Remark 4.2.** The careful reader might have noticed that, in fact, the proof of Lemma 4.1 implies a somewhat sharper claim which is however more difficult to state. Together with $r(2, n) = 2(n - 2)$, this results in a stronger statement than Theorem 1. But under such minor improvement the leading term of $\mathbf{3}$ will stay the same. In particular, these adjustments in our proof will not be sufficient to obtain a linear upper bound for $r(3, n)$ instead of the cubic one given by $\mathbf{3}$. (The reader will recall that Grassmann convexity conjecture claims that $r(3, n) = 3(n - 3)$, see Equation 1.)
