CONSTRUCTING THE DETERMINANT SPHERE USING A TATE TWIST

TOBIAS BARTHEL, AGNÈS BEAUDRY, PAUL G. GOERSS, AND VESNA STOJANOSKA

Abstract. Following an idea of Hopkins, we construct a model of the determinant sphere \( S(\det) \) in the category of \( K(n) \)-local spectra. To do this, we build a spectrum which we call the Tate sphere \( S(1) \). This is a \( p \)-complete sphere with a natural continuous action of \( \mathbb{Z} \times \mathbb{Z} \). The Tate sphere inherits an action of \( G_n \) via the determinant and smashing Morava \( E \)-theory with \( S(1) \) has the effect of twisting the action of \( G_n \). A large part of this paper consists of analyzing continuous \( G_n \)-actions and their homotopy fixed points in the setup of Devinatz and Hopkins.

1. Introduction

Let \( p \) be a prime and \( n > 0 \) an integer; these will be fixed throughout and we will always suppress \( p \) and mostly suppress \( n \) from the notation. Let \( E = E_n \) denote the Lubin–Tate spectrum associated to the Honda formal group law of height \( n \) over \( \mathbb{F}_p \), and let \( K = K(n) \) be the corresponding Morava \( K \)-theory at height \( n \) at the prime \( p \). As is the usual convention, given any spectrum \( X \), we write

\[
E_*X = \pi_*L_K(E \wedge X)
\]

where \( L_K \) denotes \( K \)-localization.

We are interested in the \( K \)-local category and, in particular, one very interesting spectrum therein which arises from comparing two dualities. The first of these duality functors is Spanier–Whitehead duality, sending \( X \) to \( D_n X = F(X, L_K S^0) \). If \( X \) is a dualizable spectrum – for example if \( X \) is a finite spectrum – then \( E_* D_n X \cong E^{**} X \) and can be computed by a universal coefficient spectral sequence. The second is Gross–Hopkins duality, sending \( X \) to \( I_n X = F(M_n X, I_{Q/Z}) \), the Brown–Comenetz dual of its monochromatic layer. Specifically, \( M_n X \) is the fiber of \( L_n X \to L_{n-1} X \) and \( I_{Q/Z} \) is the spectrum representing the cohomology theory \( I_{Q/Z}^*(X) = \text{Hom}_Z(\pi_* X, Q/Z) \). It is a consequence of the work of Gross and Hopkins that the dual \( I_n \) of the sphere \( L_K S^0 \) is invertible in the \( K \)-local category and, hence, we have for any spectrum \( X \) a natural equivalence

\[
I_n X \simeq L_K(D_n X \wedge I_n).
\]

This material is based upon work supported by the National Science Foundation under Grant No. DMS-1812122 and Grant No. DMS-1725563. Barthel was partially supported by the DNRF92 and the European Union’s Horizon 2020 research and innovation programme under the Marie Skłodowska-Curie grant agreement No. 751794. The authors would like to thank the Isaac Newton Institute for Mathematical Sciences for support and hospitality during the program Homotopy Harnessing Higher Structures when work on this paper was undertaken. This work was supported by EPSRC Grant Number EP/R014604/1.
At this point, information about the homotopy type of $I_n$ becomes vital, and one gets a handle on it using that the spectrum $E$ has an action by the Morava stabilizer group $G = G_n$. Consequently, the graded $E_n$-module $E_* X$ has a continuous action by $G$, giving it the structure of a Morava module (see Definition 5.3.20 [BB20]).

The key to the invertibility of $I_n$ is the calculation of the Morava module $E_* I_n$. The group $G$ is a semidirect product $S \rtimes \text{Gal}(\mathbb{F}_p^n/\mathbb{F}_p)$, where $S = S_n$ is the automorphism group of the formal group law of $K$. The group $S$ can be identified with a subgroup of the general linear group $\text{GL}_n(K_w)$, where $\mathcal{W}$ denotes the Witt vectors on the finite field $\mathbb{F}_p$. The group $S$ has enough symmetry that the determinant $\text{GL}_n(\mathcal{W}) \to \mathcal{W}^\times$ restricts to a homomorphism

$$\text{det}: S \to \mathbb{Z}_p^\times,$$

which can be extended to $G$ as the composite

$$\text{det}: G = S \rtimes \text{Gal}(\mathbb{F}_p^n/\mathbb{F}_p) \xrightarrow{\text{det} \times \text{id}} \mathbb{Z}_p^\times \times \text{Gal}(\mathbb{F}_p^n/\mathbb{F}_p) \xrightarrow{\text{proj}} Z_p^\times.$$ 

This gives a $G$-action on $Z_p$, and we write the corresponding representation as $Z_p(\text{det})$. If $M$ is a Morava module, we can define a new Morava module by $M(\text{det}) = M \otimes_{Z_p} Z_p(\text{det})$ with the diagonal $G$-action. Then we have by [HG94] and [Str00] an isomorphism of Morava modules

$$E_* I_n = E_*(S^{n^2-n})(\text{det}).$$

If the prime is large ($2p > \max\{n^2 + 1, 2n + 2\}$) this determines the homotopy type of $I_n$. If the prime is not large, then we would like a fixed model $S(\text{det})$ of an invertible spectrum in the $K$-local category equipped with an isomorphism

$$E_* S(\text{det}) \cong E_*(\text{det}).$$

Then we have a $K$-local equivalence

$$I_n \simeq S^{n^2-n} \wedge S(\text{det}) \wedge P_n,$$

where $P_n$ is an invertible $K$-local spectrum with $E_* P_n \cong E_* S^0$ as Morava modules, and attention turns to identifying $P_n$. In the known cases this comes down to calculating the homotopy groups of $I_n X$ for $X$ a particularly nice type $n$ complex. See [HMS94] for analysis of $P_n$ at $n = 2 = p - 1$; the case $n = 1 = p - 1$ was done by [HMS94] and also appears in [HS14, GHMR15].

The point of this note is to give a construction of a model of $S(\text{det})$ valid at all primes $p$ and all $n > 0$. We actually give two constructions of $S(\text{det})$, one using homotopy fixed points, following an idea of Mike Hopkins, and another, more naive and direct one, following ideas from [GHMR15, Wes17], fixing the typos therein and extending the construction to the prime 2. A different construction of $S(\text{det})$, valid at primes large with respect to the given height and choice-free, was given by Peterson in [Pet20, Cor. 3]. Since the Morava module determines an invertible $K$-local object at large primes, the two constructions give equivalent spectra in this situation.

The first model will evidently have the property that $L_K(E^{hk} \wedge S(\text{det})) = E^{hk}$ for all closed subgroups $k$ in the kernel of the determinant. The key to this construction is to introduce a spectrum $S(1)$ with a continuous $G$-action, non-equivariantly equivalent to the $p$-complete sphere spectrum $S^0 = S^0_p$, and such that smashing
with it naturally twists $G$–actions by the determinant representation. Then we define

$$S(\det) = (E \wedge S(1))^hG,$$

the action on the right-hand side being diagonal. The following is our main result.

**Theorem 3.10.** There is a canonical $G$-equivariant equivalence $f : E \wedge S(\det) \to E \wedge S(1)$, where the action of $G$ on the source is via the action on $E$, while on the target it is diagonal. This induces an isomorphism of Morava modules $E_* S(\det) \cong E_* (E \wedge S(1))^hG$.

If $K$ is a closed subgroup of $G$ in the kernel of the determinant, taking $K$-homotopy fixed points in this equivalence gives the desired result (Corollary 3.11)

$$E^hK \wedge S(\det) \cong (E \wedge S(1))^hK \cong E^hK.$$

This project gives a chance to revisit and give an encomium on the amazing paper of Devinatz and Hopkins on fixed point spectra in the $K$-local category [DH04]. Distilled down we have the following question: let $X$ be a spectrum with a continuous action of the Morava stabilizer group $G$. We can then form the $G$-spectrum $Z = E \wedge X$ with diagonal $G$-action and discuss the homotopy type of $Z^hG = (E \wedge X)^hG$. Note that $E_* Z = \pi_* L_K(E \wedge Z)$ has two $G$-actions: the Morava module action on $E$ and the action on $Z$. A consequence of our results is that if $X$ is dualizable in the $K$-local category, then

$$E_* (Z^hG) = E_* (E \wedge X)^hG \cong E_* X$$

and the Morava module action on $E_* (E \wedge X)^hG$ corresponds to the diagonal action on

$$E_* X = \pi_* L_K(E \wedge X).$$

An analogue of this result for arbitrary spectra $X$ with trivial $G$-action was proven by Davis and Torii [DT12]. The equivalence (1.1) is not hard to prove once we have come to terms with the notion of a continuous $G$-action. Since we are making a homology calculation we need cosimplicial techniques, and this is exactly what Devinatz and Hopkins supply.

We close with a remark on our choice of the formal group we use to specify Morava $K$-theory and $E$-theory. At the beginning of this introduction, we specified the Honda formal group over $\mathbb{F}_p$. This was simply because [DH04] is written for the Honda formal group. Presumably, the work of Devinatz and Hopkins goes through without change for any height $n$ formal group over any finite extension $\mathbb{F}_q$ of the prime field $\mathbb{F}_p$. If this is the case, we could choose any $F$ so that the map $\det : \text{Aut}(F/\mathbb{F}_q) \to \mathbb{Z}_p^\times$ is surjective.

**Acknowledgements.** We would like to thank Hans-Werner Henn, Mike Hopkins and Charles Rezk for helpful conversations and the referee for their comments.

2. **Continuous $G$ actions and their homotopy fixed points**

As is perhaps apparent from the introduction, we will assume our readership has access to the standard framework of $K$-local homotopy theory. The usual source for an in-depth study of the technicalities is Hovey and Strickland [HS99] and basic introductions can be found in almost any paper on chromatic homotopy theory. We were especially thorough in [BGH17, §2].
Remark 2.1. Before we proceed further, we need to establish some more notation. Using the periodicity results of Hopkins and Smith [HS98], Hovey and Strickland produce a sequence of ideals $J(i) \subseteq m \subseteq E_0$ and finite type $n$ spectra $M_{J(i)}$ with the following properties:

1. $J(i + 1) \subseteq J(i)$ and $\bigcap_i J(i) = 0$;
2. $E_0/J(i)$ is finite;
3. $E_0(M_{J(i)}) \cong E_0/J(i)$ and there are spectrum maps $q: M_{J(i+1)} \to M_{J(i)}$ realizing the quotient $E_0/J(i+1) \to E_0/J(i)$;
4. There are maps $\eta = \eta_i: S^0 \to M_{J(i)}$ inducing the quotient map $E_0 \to E_0/J(i)$ and $q_0i+1 = \eta_i: S^0 \to M_{J(i)}$;
5. If $X$ is a finite type $n$ spectrum, then the map $X \to \holim_i (X \wedge M_{J(i)})$ induced by the maps $\eta$ is an equivalence.
6. If $X$ is any $L_n$-local spectrum then by [HS99] we have $L_\mathbb{K}X \simeq \holim_i X \wedge M_{J(i)}$. In particular we have $E \simeq \holim_i E \wedge M_{J(i)}$.

Most of this is proved in [HS99, § 4], and (6) is proved in [HS99, Prop. 7.10]. Hovey and Strickland also prove that items (1)- (5) characterize the tower $\{M_{J(i)}\}$ up to equivalence in the pro-category of towers under $S^0$. See Proposition 4.22 of [HS99]. Note that the sequence $\{J(i)\}$ of ideals defines the same topology on $E_0$ as the $m$-adic topology and that $G$ acts on $E_0/J(i)$ through a finite quotient.

For profinite sets $T = \lim_j T_j$ and $A = \lim_i A_i$, recall that the set of continuous maps from $T$ to $A$ is defined as

$$\Map^c(T, A) = \lim_i \colim_j \Map(T_j, A_i).$$

Let $M$ be a Morava module and always assume $M$ is $m$-complete. An important example of the previous construction is the Morava module of continuous maps

$$\Map^c(G, M) = \lim_i \Map^c(G, M/m^i) = \lim_i \colim_j \Map(G/U_j, M/m^i)$$

where $U_{j+1} \subseteq U_j \subseteq G$ is a nested sequence of open normal subgroups so that $\cap U_j = \{e\}$; then $G = \lim_j G/U_j$.

We now begin to make these constructions topological by giving a definition of a spectrum of continuous maps in the $\mathbb{K}$-local category.
Definition 2.2. Suppose $T = \lim_j T_j$ is a profinite set, and $A \simeq \holim_i A \wedge M_{J(i)}$ is a $K$-local spectrum. Define

$$F_c(T_+, A) = \holim_i \holim_j F(T_{j_+}, A \wedge M_{J(i)}).$$

In applications $T$ will be a $G$ or $G/K \times \mathbb{G}^s$ with $s \geq 0$ and $K \subseteq G$ a closed subgroup, or $G = \mathbb{Z}_p^\infty$.

We now calculate $\pi_* F_c(T_+, A)$, at least for some $A$. For later applications, we will need a slightly more general result about $\pi_* F(Z, F_c(T_+, A))$ with $Z$ arbitrary. If $Z$ is any spectrum we may write $Z \simeq \holim Z'^i$ for some filtered collection of finite spectra. If $A \simeq \holim_i A \wedge M_{J(i)}$ is a $K$-local spectrum, then we have a topology on $\pi_* F(Z, A) = A^{-t}(Z)$ defined by the open system of neighborhoods of zero given by the kernels of the map

$$\pi_* F(Z, A) \rightarrow \pi_* F(Z'^i, A \wedge M_{J(i)}).$$

This is the natural topology of [HS99, Section 11]. The groups $\pi_* F(Z, A)$ are complete in this topology if

$$\pi_* F(Z, A) \cong \lim_{\alpha,i} \pi_* F(Z'^i, A \wedge M_{J(i)}).$$

In applying the following result our main example will be $A = E \wedge X$ with $X$ dualizable in the $K$-local category.

Lemma 2.3. Suppose $Z$ is any spectrum, $T = \lim_j T_j$ is a profinite set, and $A \simeq \holim_i A \wedge M_{J(i)}$ is a $K$-local spectrum. Further suppose $\pi_i (A \wedge M_{J(i)})$ is finite for all $i$ and $t$. We then have an isomorphism

$$\pi_* F(Z, F_c(T_+, A)) \cong \Map(T, A^{-*}Z)$$

where $A^{-*}Z$ is equipped with the natural topology.

Proof. Let $Z \simeq \holim_\alpha Z'^\alpha$ be some cellular filtration on $Z$ by finite spectra. Our finiteness hypothesis on $A$ implies

$$A^{-*}Z = \pi_* F(Z, A) \cong \lim_{\alpha,i} \pi_* F(Z'^i, A \wedge M_{J(i)}).$$

Now we have that

$$F(Z, F_c(T_+, A)) \simeq \holim_\alpha \holim_j F(Z'^i, \holim_j F(T_{j_+}, A \wedge M_{J(i)}))$$

is equivalent to

$$\holim_\alpha \holim_j \holim_i F(Z'^i, F(T_{j_+}, A \wedge M_{J(i)})),$$

since $Z'^i$ is dualizable. The homotopy groups of

$$F(Z'^i, F(T_{j_+}, A \wedge M_{J(i)})) \simeq F(T_{j_+}, F(Z'^i, A \wedge M_{J(i)}))$$

are $\Map(T, \pi_* F(Z'^i, A \wedge M_{J(i)}))$ and the claim follows using the Milnor sequence and our finiteness hypotheses for the vanishing of the $\lim^1$ term.

Remark 2.4. For a $K$-local spectrum $X \simeq \holim_i X \wedge M_{J(i)}$, we can give

$$F((G/U_j)_+, X \wedge M_{J(i)})$$

a left $G = \lim_i G/U_i$ action by operating on the right on the source. (Note that the subgroups $U_j$ are normal.) This assembles into an action on $F_c(G_+, X)$. If
the homotopy groups $\pi_t(X \wedge M_{J(i)})$ are finite, Lemma 2.3 gives an isomorphism of continuous $G$-modules

$$\pi_* F_c(G^+, X) \cong \text{Map}^c(G, \pi_* X)$$

(2.1)

where again $G$ acts on the source.

Writing $G^s = \lim(G/U_i)^s$ we define $F_c(G^+, X)$ for $s \geq 1$ as in Definition 2.2. We have that

$$F_c(G^s, F_c(G^t, X)) \simeq F_c(G^{s+t}, X).$$

The equation $F_c(G^{s+1}, X) \simeq F_c(G^s, F_c(G^+, X))$ defines an action of $G$ on $F_c(G^{s+1}, X)$ using the right action on the first factor of $G^{s+1}$.

Evaluation defines a map $G_+ \wedge F((G/U_i)_+, X \wedge M_{J(i)}) \to X \wedge M_{J(i)}$. Here $G$ is simply regarded as a set, with no topology. These fit together to give a map

$$G_+ \wedge F_c(G^+, X) \to X.$$

We now come to the Devinatz–Hopkins notion of a continuous $G$–action on a $K$-local spectrum. To prepare, we spend a few paragraphs examining the standard bar construction in equivariant homotopy theory.

Let $G$ be a discrete group and $X$ a $G$-space. Then we can form the augmented cosimplicial space

$$X \to \text{map}(G^{s+1}, X)$$

(2.2)

with coface maps defined by

$$(d^i \phi)(g_0, g_1, \ldots, g_s) = \begin{cases} g_0 \phi(g_1, \ldots, g_s), & s = 0; \\ \phi(g_0, \ldots, g_{i+1}, g_s), & s \geq 1. \end{cases}$$

The codegeneracy maps $s^i$ insert the unit in the $i$th slot and the augmentation $\eta: X \to \text{map}(G, X)$ is adjoint to the action map $G \times X \to X$. Notice that $s^i$ for all $i$, and $d^s$ for all $i \geq 1$ depend only on $G$, and not on the action of $G$ on $X$. However, for all $s$, $d^0$ is given by the composition

$$\text{map}(G^s, X) \xrightarrow{\text{map}(G^s, \eta)} \text{map}(G^s, \text{map}(G, X)) \cong \text{map}(G^{s+1}, X),$$

where we have used the adjoint isomorphism $\text{map}(Y, \text{map}(G, X)) \cong \text{map}(G \times Y, X)$.

We could turn these observations around and define a $G$-action on $X$ as a map

$$\eta: X \to \text{map}(G, X)$$

so that the diagram (2.2) determined by these formulas is an augmented cosimplicial space; that is, the various compositions satisfy the cosimplicial identities. We find that this is equivalent to the usual definition.

There is nothing special about spaces in this discussion: for example, an action of $G$ on a spectrum $X$ defines and is defined by an augmented cosimplicial spectrum

$$X \to F(G^{s+1}, X).$$

In our definition of a continuous $G$–spectrum, which again is essentially due to Devinatz–Hopkins [DH04], we replace the functors $F(G^{s+1}, -)$ by the functors $F_c(G^{s+1}, -)$.

**Definition 2.5 (Continuous $G$-actions).** Let $X$ be a $K$-local spectrum. A continuous $G$–action on $X$ consists of a map

$$\eta = \eta_X: X \to F_c(G^+, X)$$
so that the diagram
\[(2.3) \quad X \longrightarrow F_c(G_+^{\star+1}, X)\]
determined by \(\eta\) and \(G\) is an augmented cosimplicial spectrum.

A map of continuous \(G\)-spectra consists of a map of the respective augmented cosimplicial diagrams.

**Remark 2.6.** If \(X\) has a \(G\)-action, then the composition
\[(2.4) \quad X \overset{\eta}{\longrightarrow} F_c(G_+, X) \longrightarrow F(G_+, X)\]
defines an action (in the usual sense) of \(G\) on \(X\). Conversely given an action of \(G\) on \(X\), we say that action refines to a continuous action, or simply that the action is continuous, if there is a factoring as in (2.4) that gives \(X\) the structure of a continuous \(G\)-spectrum.

This is what Devinatz–Hopkins [DH04] accomplish, where the discrete \(G\)-action on \(E\) was already given by the Goerss–Hopkins–Miller theorem. We discuss this example further in Remark 2.13 below.

**Example 2.7.** A more tautological example is the following: For any \(K\)-local spectrum \(X\), the trivial action of \(G\) on \(X\) is continuous. Here we start with \(\eta\): \(X \to F_c(G_+, X)\) adjoint to the projection map \(G_+ \wedge X \to X\).

**Definition 2.8 (Homotopy fixed points).** If \(X\) is a continuous \(G\)–spectrum and \(K \subseteq G\) is a closed subgroup, we define \(F_c(G_+, X)^K = F_c(G/K_+, X)\) and
\[(2.5) \quad X^{hK} = \holim_{\Delta} F_c(G_+^{\star+1}, X)^K \simeq \holim_{\Delta} F_c(G/K_+ \wedge G^{\star}, X).\]

**Remark 2.9.** Suppose further that \(K \subseteq G\) is a closed subgroup and that \(X \simeq \holim_{i} X \wedge M_{J(i)}\) is a \(K\)-local spectrum such that \(\pi_t(X \wedge M_{J(i)})\) is finite for all \(i\) and \(t\). Using Lemma 2.3, one sees that these definitions are designed so that the Bousfield–Kan spectral sequence associated to (2.5) is the homotopy fixed point spectral sequence
\[
E_2^{s,t} = H^s(K, \pi_t X) \Longrightarrow \pi_{t-s}X^{hK}
\]
with \(E_2\)-term given by the continuous group cohomology.

**Remark 2.10.** There is an obvious generalization of this definition to other settings, for example the group may be any profinite group. Likewise, the spectrum \(X\) may live in another category where analogues of the generalized Moore spectra \(M_{J(i)}\) play a similar role. For example \(X\) may be a \(p\)-complete spectrum, so \(X \simeq \holim_{i} X \wedge S/p^i\). While we will in effect construct a continuous \(p\)-complete \(Z_p^{\infty}\) spectrum in this sense in Section 3, we refrain from setting up a general theory.

The following is an easy but useful property, which we record as a lemma for convenient future reference.

**Lemma 2.11.** Let \(X\) be a continuous \(G\)-spectrum. If \(X^{hG}\) is given the trivial \(G\)-action, the “inclusion of fixed points” map \(X^{hG} \to X\) is \(G\)-equivariant.

**Proof.** The map in question is \(\holim_{\Delta}\) of the cosimplicial map
\[
F_c(G_+^{\star}, X) \simeq F_c(G_+^{\star+1}, X) \overset{G}{\longrightarrow} F_c(G_+^{\star+1}, X),
\]
given by the inclusion of fixed points, which by construction has the required properties.

One way to summarize the results of Devinatz and Hopkins [DH04] is as follows. The phrase “essentially unique” means the space of choices is contractible.

**Theorem 2.12.** The $G$-spectrum $E$ has an essentially unique structure as a continuous $G$-spectrum with the property that if $K \subseteq G$ is closed, then the map of Morava modules $E_*E^{hK} \rightarrow E_*E$ is naturally isomorphic to the inclusion

$$\text{Map}^c(G/K, E_*) \rightarrow \text{Map}^c(G, E_*).$$

The Morava modules $E_*E^{hK}$ and $E_*E$ are discussed in more details immediately after Remark 2.13.

**Remark 2.13.** The statement of Theorem 2.12 at once disguises quite a bit of difficult work and obscures the logic of the Devinatz–Hopkins argument; thus, it is surely worth going into a bit of detail.

Suppose for a moment that we knew that Theorem 2.12 was true. As above, choose a nested sequence of open normal subgroups $U_{j+1} \subseteq U_j \subseteq G$ with $\cap U_j = \{e\}$. Then we would have a sequence of spectra

$$\cdots \rightarrow E^{hU_j} \rightarrow E^{hU_{j+1}} \rightarrow \cdots \rightarrow E$$

with the following properties

1. $E^{hU_j}$ is a $G/U_j$ spectrum and all the maps of (2.6) are $G$-equivariant;
2. the map $E_*E^{hU_j} \rightarrow E_*E$ of Morava modules is isomorphic to the inclusion

$$\text{Map}^c(G/U_j, E_*) \rightarrow \text{Map}^c(G, E_*);$$
3. the induced map $\text{hocolim}_j E^{hU_j} \rightarrow E$ is a $K$-local equivalence.

Let us give some detail on Part (3). By Remark 2.1, Part (6) we have that if $X$ is $L_n$-local then $L_KX = \text{holim}_X \wedge M_{J(i)}$. The spectra $E^{hU_j}$ are $K$-local and, hence $L_n$-local. Since $L_n$ is smashing the homotopy colimit is $L_n$-local, so Part (3) is equivalent to the statement that

$$\text{hocolim}_j E^{hU_j} \wedge M_{J(i)} \rightarrow E \wedge M_{J(i)}$$

is an equivalence for all $i$. This follows from (2) and the fact that $\cap U_j = \{e\}$.

Next observe that since $G/U_j$ is finite, $E_*E^{hU_j}$ is finitely generated as an $E_*$-module, hence $E^{hU_j}$ is dualizable in the $K$-local category, by [HS99, Thm. 8.6]. Putting all this together – and still assuming we know Theorem 2.12 – we would have the following diagram of cosimplicial spectra, with the vertical maps being $K$-local equivalences

$$\begin{array}{ccc}
\text{hocolim}_j E^{hU_j} & \rightarrow & \text{hocolim}_j F((G/U_j)_{+}^*, E^{hU_j}) \\
\approx & & \approx \\
E \rightarrow & & F_c(G_{+}^*, E).
\end{array}$$

Devinatz and Hopkins prove Theorem 2.12 by reversing the logical order of this discussion: Recall that the Goerss–Hopkins–Miller theorem provides $E$ with an essentially unique structure as an $E_\infty$-ring spectrum, the space map$_{E_\infty}(E, E)$ has
contractible components, and \( \pi_0 \text{map}_{E_{\infty}}(E, E) \cong \mathbb{G} \). This gives \( E \) an essentially unique structure as \( \mathbb{G} \)-spectrum, with the action through \( E_{\infty} \)-ring maps.

Using the Goerss–Hopkins–Miller Theorem, Devinatz and Hopkins define a sequence of spectra which they call \( E^{hL} \) and maps as in (2.6) satisfying Parts (1)–(3) above. They then define the continuous \( \mathbb{G} \)-structure on \( E \) using the diagram of (2.7). Then they must justify the notation \( E^{hL} \); that is, they must show the spectra defined this way agree, up to equivalence, with the fixed points as defined in (2.5). Finally, they must calculate \( E_\ast E^{hK} \). For this they use the remarkable Proposition 2.16 below.

We further unpack the statement of Theorem 2.12 and generalize it (Proposition 2.17 and Corollary 2.18). For any \( X \),

\[ E_\ast(E \wedge X) = \pi_\ast L_K(E \wedge E \wedge X) \]

is a Morava module, using the action of \( \mathbb{G} \) on the left factor \( E \). Now, suppose \( X \) itself has a \( \mathbb{G} \)-action so that the diagonal action on \( E \wedge X \) is continuous. If \( h \in \mathbb{G} \) and \( x \in E \wedge X \), then we write \( h \ast x \) for this action. The adjoint of the diagonal action of \( \mathbb{G} \) on \( E \wedge X \) gives rise to a map

\[ \eta: E_\ast(E \wedge X) \longrightarrow \text{Map}^\ast(\mathbb{G}, E_\ast X). \]

Explicitly, if \( x: S^1 \rightarrow E \wedge E \wedge X \) and \( g \in \mathbb{G} \), then \( \eta(x)(g) \) is the composite

\[ S^1 \longrightarrow E \wedge E \wedge X \xrightarrow{1 \wedge g \wedge 1} E \wedge E \wedge X \xrightarrow{\mu \wedge 1} E \wedge X, \]

where \( \mu \) is multiplication and we have suppressed the \( K \)-localizations.

If \( X \) is \( S^0 \) with the trivial action, then \( \eta \) gives the identification of \( E_\ast E \) with \( \text{Map}^\ast(\mathbb{G}, E_\ast) \) which appeared in Theorem 2.12. The following result covers every case that arises in this note.

**Lemma 2.14.** Suppose \( X = Y \wedge Z \) where \( K_\ast Y \) is zero in odd degrees and \( Z \) is a \( K \)-locally dualizable spectrum. Then the map \( \eta \) in (2.8) is an isomorphism.

**Proof.** As in the proof of [GHMR05, Prop. 2.4], it suffices to show that the natural map

\[ E_\ast(E \wedge X) \longrightarrow \lim_i E_\ast(E \wedge M_{J(i)} \wedge X) \]

occurring in the Milnor sequence associated to \( \text{holim}_i E \wedge E \wedge X \wedge M_{J(i)} \) is an isomorphism, i.e., that \( \lim^1_i E_\ast(E \wedge M_{J(i)} \wedge X) = 0 \). The assumption on \( Y \) implies that \( E_\ast(Y) \) is a flat \( E_\ast \)-module, so there is an isomorphism

\[ E_\ast(E \wedge M_{J(i)} \wedge X) \cong E_\ast E \otimes E_\ast(X) \otimes E_\ast(M_{J(i)} \wedge Z). \]

Since \( Z \) is dualizable, \( M_{J(i)} \wedge Z \) is \( K \)-locally compact, hence \( E_\ast(M_{J(i)} \wedge Z) \) is finite. This shows that the tower \( (E_\ast(M_{J(i)} \wedge Z))_i \) is Mittag-Leffler, which implies that the required \( \lim^1 \) vanishes.

**Remark 2.15.** We now have (at least) two actions to keep straight.

1. For the Morava module structure on \( E_\ast(E \wedge X) \) the isomorphism \( \eta \) becomes \( \mathbb{G} \)-equivariant if we give the module of functions the conjugation action

\[ (h \phi)(g) = h \ast \phi(h^{-1} g). \]
(2) The diagonal action on $E \wedge X$ gives an action of $G$ on $E_*(E \wedge X)$; this involves the right factor of $E$. With respect to this action $\eta$ becomes $G$-equivariant if we give the module of functions the action 
\[(h \star \phi)(g) = \phi(gh).\]

Note that the two actions commute.

At this point, we need the following remarkable result due to Devinatz and Hopkins.

**Proposition 2.16.** Let $W^\bullet$ be a cosimplicial spectrum. Suppose there exists an integer $N$ and a finite type 0 spectrum $Y$ so that for all spectra $Z$ the Bousfield–Kan spectral sequence

$$\pi^s \pi_t F(Z, Y \wedge W^\bullet) \Rightarrow \pi_{t-s} F(Z, \text{holim}_\Delta(Y \wedge W^\bullet))$$

has a horizontal vanishing line of intercept $s = N$ at the $E_\infty$-page. Then for any spectra $A$ and $F$ and maps $v : \Sigma^k A \to A$, there is an equivalence

$$v^{-1}L_F(A \wedge \text{holim}_\Delta W^\bullet) \simeq \text{holim}_\Delta(v^{-1}L_F(A \wedge W^\bullet)).$$

**Proof.** This is all contained in [DH04, §5], even if it is not explicitly stated this way. More specifically, we combine the material before their Lemma 5.11, Lemma 5.12, and the argument given in the proof of their Theorem 5.3, substituting our $Y$ for their spectrum $X$. \[\square\]

**Proposition 2.17.** Let $X$ be a $G$-spectrum, which is (K-locally) dualizable, and such that the diagonal action of $G$ on $E \wedge X$ is continuous. Then for a closed subgroup $K$ of $G$ and any spectrum $A$, there is a $K$-local equivalence

$$A \wedge (E \wedge X)_{hK} \simeq (A \wedge E \wedge X)_{hK},$$

where on the right-hand side, $K$ is acting trivially on the first factor.

**Proof.** We will prove this by applying Proposition 2.16 (with $F = K$, and $v = \text{id}$) to the cosimplicial spectrum which computes the homotopy fixed points $(E \wedge X)_{hK}$. Specifically, $(E \wedge X)_{hK} \simeq \text{holim}_\Delta W^\bullet$, with

$$W^s = F_c(G^{s+1}_+, E \wedge X)^K = F_c(G/\langle k \rangle_+ \wedge G^{s+1}_+, E \wedge X).$$

We need to check that the conditions of Proposition 2.16 are satisfied; then the result follows. The argument we give exactly mirrors that of [DH04, Theorem 5.3].

We choose $Y$ to be a finite type 0 spectrum so that $E_0 Y$ is free as a $C$-module for every cyclic subgroup $C \subseteq G$ of order $p$ and so that $E_1 Y = 0$. Moreover, $E_0 Y$ is free as an $E_*$-module. Such a spectrum $Y$ is constructed by Jeff Smith; see [Rav92, §6.4, 8.3, 8.4].

Since both $X$ and $Y$ are dualizable, Lemma 2.3 gives us that, for any spectrum $Z$, there is an isomorphism

$$\pi_t F(Z, Y \wedge W^\bullet) \cong \text{Map}^C(G^{s+1}_+, \pi_t F(Z, E \wedge X \wedge Y))^K.$$

Using again that $X$ and $Y$ are dualizable as well as that $E_* Y$ is in even degrees and free over $E_*$,

$$\pi_t F(Z, E \wedge X \wedge Y) \cong E^{-t}(Z \wedge DX) \otimes_{E_0} E_0(Y).$$
Now $E_0(Y)$ is free as a $C$-module for every cyclic subgroup $C \subseteq G$ of order $p$, so the same is true for $\pi_1 F(Z, E \wedge X \wedge Y)$, and that fact implies that

$$\pi^s \pi_t F(Z, Y \wedge W^*) \cong H^s(K, E^{-i}(Z \wedge DX) \otimes_{E_0} E_0(Y))$$

is zero for $s > n^2$ [Rav92, Lemma 8.3.5]. In particular, this gives a horizontal vanishing line at the $E_2$-page, and Proposition 2.16 applies to give the claim. □

**Corollary 2.18.** If $X$ and $k$ are as in Proposition 2.17, then there is an isomorphism of Morava modules

$$E_*(\langle E \wedge X \rangle^{hK}) \cong \text{Map}^c(\mathbb{G}/k, E_*(X))$$

where the Morava module structure on the right-hand side is the conjugation action described in Remark 2.15.

**Proof.** Proposition 2.17 implies that $E_*(\langle E \wedge X \rangle^{hK}) \cong \pi_*(E \wedge X)^{hK}$. We will use the homotopy fixed point spectral sequence computing $\pi_*(E \wedge X)^{hK}$. As was discussed in Remark 2.15, there is a $k$-equivariant isomorphism

$$E_*(E \wedge X) \cong \text{Map}^c(G, E_*(X))$$

with the $k$-action on $E_*(E \wedge X) = \pi_*(E \wedge E \wedge X)$ the diagonal action on the right two factors and the $k$-action on $\text{Map}^c(G, E_*(X))$ is right multiplication on the source. It follows that the $E_2$-term of the homotopy fixed point spectral sequence is

$$H^s(K, \pi_*(E \wedge E \wedge X)) \cong H^s(k, \text{Map}^c(G, E_*(X))).$$

Furthermore

$$H^s(k, \text{Map}^c(G, E_*(X))) \cong \begin{cases} \text{Map}^c(G/k, E_*(X)), & s = 0; \\ 0, & s \neq 0 \end{cases}$$

since $\text{Map}^c(G, E_*(X))$, is induced as $G$-module, and hence as $k$-module. Thus, the homotopy fixed point spectral sequence collapses and the edge homomorphism gives an isomorphism of Morava modules

$$E_*(\langle E \wedge X \rangle^{hK}) \cong (E_*(E \wedge X))^K \cong \text{Map}^c(G/k, E_*(X)).$$

□

3. The Tate sphere and the determinant sphere

In order to define the determinant sphere, we need a spectrum-level construction which twists actions. This is accomplished by a sphere spectrum we suggestively denote by $S(1)$, to be indicative of a Tate twist. Namely, $S(1)$ is the $p$-completed sphere spectrum $S^0$ with a continuous action of $\mathbb{Z}_p^\times$ coming from its action as automorphisms on $\pi_0 S^0$, to be constructed below.

We can also consider $S(1)$ as a spectrum with a $G$-action, where $G$ acts through the determinant homomorphism

$$\det : G \to \mathbb{Z}_p^\times,$$

defined as in [GHMR05, Section 1.3]. The determinant is a surjection and we let $SG$ denote its kernel, so that there is an exact sequence

$$1 \to SG \to G \to \mathbb{Z}_p^\times \to 1.$$
We will then define $S(\det)$ as the homotopy fixed points of a particular $\mathbb{G}$-spectrum in the $K$-local category.

We now begin the construction of $S(1)$; we will start by constructing a discrete action of a dense subgroup of $\mathbb{Z}_p^\times$. If $p > 2$, we have a decomposition

$$(1 + p\mathbb{Z}_p) \times \mathbb{Z}_p^\times$$

where $\mathbb{Z}_p^\times$ is the cyclic group of order $p - 1$ given by the Teichmüller lifts. Let $C \subseteq 1 + p\mathbb{Z}_p$ be the infinite cyclic subgroup generated by $\tau = 1 + p \in 1 + p\mathbb{Z}_p$.

If $p = 2$, we have a slightly different decomposition

$$(1 + 4\mathbb{Z}_2) \times \mathbb{Z}_2^\times$$

where now $\mathbb{Z}_2^\times = \{\pm 1\}$. Let $C$ be generated by $\tau = 1 + 4 = 5 \in 1 + 4\mathbb{Z}_2$.

With this setup, we write $G = C \times \mu$ for all primes. Note that $G$ is a dense subgroup of $\mathbb{Z}_p^\times$, and $\tau$ is a generator of the torsion-free subgroup $C \cong \mathbb{Z}$. If $p > 2$ the inclusion $C \to 1 + p\mathbb{Z}_p$ completes to an isomorphism $\mathbb{Z}_p^\times \cong 1 + p\mathbb{Z}_p$. At $p = 2$ we get a similar isomorphism $\mathbb{Z}_2^\times \cong 1 + 4\mathbb{Z}_2$.

**Proposition 3.1.** The inclusion $G \to \mathbb{Z}_p^\times = \pi_1 \text{Bhaut}(S^0)$ can be canonically realized by a map

$$BG \to \text{Bhaut}(S^0).$$

**Proof.** Since $\text{Bhaut}(S^0)$ is an infinite loop space we need only realize separately the maps $C \to \mathbb{Z}_p^\times$ and $\mu \to \mathbb{Z}_p^\times$ as maps $BC \to \text{Bhaut}(S^0)$ and $B\mu \to \text{Bhaut}(S^0)$. The map we want will then be the composite

$$BG \simeq BC \times B\mu \to \text{Bhaut}(S^0) \times \text{Bhaut}(S^0) \to \text{Bhaut}(S^0)$$

where the second map is the loop space multiplication.

At all primes $BC \simeq B\mathbb{Z} \simeq S^1$ and the choice of $\tau$ defines the required map $S^1 \to \text{Bhaut}(S^0)$.

If $p = 2$, then $B\mu \simeq B\mathbb{Z}/2 \simeq BO(1)$ and the map we need is defined by the composition

$$BO(1) \to BO \to \text{Bhaut}(S^0).$$

Suppose $p > 2$ and let $A$ be some 2-skeleton of $B\mu$. The inclusion $\mu \subseteq \mathbb{Z}_p^\times$ defines a map $A \to \text{Bhaut}(S^0)$ by extending a generator of $\mu \subset \pi_1 \text{Bhaut}(S^0)$ to $A$. Since $\pi_i \text{Bhaut}(S^0) \cong \pi_{i-1} S^0$ is $p$-complete for $i \geq 2$ and $\mu$ has order prime to $p$, the map out of $A$ extends uniquely to a map $B\mu \to \text{Bhaut}(S^0)$. \hfill $\square$

Let $k \geq 1$ and let $G_k \subseteq G$ be the kernel of the composition

$$G \twoheadrightarrow \mathbb{Z}_p^\times \to (\mathbb{Z}/p^k)^\times.$$ 

If $p > 2$, then $G_1 = C$ and $G_k$ is infinite cyclic generated by $\tau^{p^k-1}$. If $p = 2$, then $G_2 = C$ and for $k > 1$ the group $G_k$ is infinite cyclic generated by $\tau^{p^{k-2}}$. We have that the intersection $\cap G_k$ is trivial, and $\lim_k G/G_k \cong \mathbb{Z}_p^\times$; thus, the subgroups $G_k$ define the usual topology on $\mathbb{Z}_p^\times$. 

Proposition 3.2. Let \( \widetilde{S}(1) \) be the \( p \)-complete sphere spectrum with the discrete action of \( G \) constructed above. If \( p \) is odd let \( k \geq 1 \) and if \( p = 2 \) let \( k > 1 \). Then there is an equivalence
\[
S/p^k \cong EG_+ \wedge_{G_k} \widetilde{S}(1)
\]
and the residual action of \( G/G_k \cong (\mathbb{Z}/p^k)\times \) realizes the standard action of \( (\mathbb{Z}/p^k)\times \) on \( \mathbb{Z}/p^k \cong \pi_0 S/p^k \).

Proof. The homotopy orbit spectrum \( EG_+ \wedge_{G_k} \widetilde{S}(1) \) is a connected spectrum and we have a homotopy orbit spectral sequence for \( H_*(-) = H_*(-, \mathbb{Z}) \):
\[
E^2_{p,q} \cong H_p(G_k, H_q \widetilde{S}(1)) \Rightarrow H_{p+q}(EG_+ \wedge_{G_k} \widetilde{S}(1)).
\]
Let \( p > 2 \). The group \( G_k \) is infinite cyclic generated by \( \tau p^{k-1} \) where \( \tau = 1 + p \).
Since \( \tau p^{k-1} \equiv 1 + p \) modulo \( p+1 \) we have \( E^2_{p,q} = 0 \) unless \( (p,q) = (0,0) \) and there is a surjection of \( G \)-modules
\[
\mathbb{Z}_p \cong H_0(\widetilde{S}(1)) \rightarrow H_0(G_k, H_0(\widetilde{S}(1))) \cong \mathbb{Z}/p^k.
\]
It follows that \( EG_+ \wedge_{G_k} \widetilde{S}(1) \) must be a Moore spectrum for \( \mathbb{Z}/p^k \) with the standard action of \( \mathbb{Z}/p^k \) on \( \pi_0 S/p^k \). The proof at the prime 2 is completely analogous. \( \square \)

Recall that continuous actions were discussed in Section 2. See in particular Definition 2.5 and Remark 2.10.

Proposition 3.3. The \( G \)-action on \( \widetilde{S}(1) \) extends to a continuous action of the profinite group \( \mathbb{Z}_p^\times \), in the sense that we have an augmented cosimplicial spectrum
\[
\widetilde{S}(1) \rightarrow F_c((\mathbb{Z}_p^\times)^{\bullet+1}, \widetilde{S}(1)),
\]
so that the augmentation refines the \( \mathbb{Z}_p^\times \)-action.

Proof. Write \( S/p^k(1) \) for \( EG_+ \wedge_{G_k} \widetilde{S}(1) \) with its \( G/G_k \cong (\mathbb{Z}/p^k)\times \)-action. Then the augmented cosimplicial spectra
\[
S/p^k(1) \rightarrow F((G/G_k)^{\bullet+1}, S/p^k(1))
\]
assemble to give a map
\[
\widetilde{S}(1) \cong \operatorname{holim}_k S/p^k(1) \rightarrow \operatorname{holim}_k \operatorname{hocolim}_j F((G/G_j)^{\bullet+1}, S/p^k(1))
= F_c((\mathbb{Z}_p^\times)^{\bullet+1}, \widetilde{S}(1))
\]
as needed. \( \square \)

Definition 3.4. We will write \( S(1) \) for the \( p \)-complete sphere \( S^0 \) with the continuous \( \mathbb{Z}_p^\times \)-action of Proposition 3.3. The same construction gives \( S(1) \) as a continuous \( p \)-complete \( G \)-spectrum, where \( G \) acts through the determinant surjection \( \det : G \rightarrow \mathbb{Z}_p^\times \).

We refer to this equivariant sphere as the Tate sphere.

Now we take the Morava \( E \)-theory spectrum \( E \) and give \( E \wedge S(1) \) the diagonal \( \mathbb{G} \)-action. The next result indicates that this is an interesting construction.

Proposition 3.5. There is an isomorphism of Morava modules
\[
E_* \langle \det \rangle \cong \pi_*(E \wedge S(1)) = E_* S(1).
\]
Proof. The edge map of the Tor spectral sequence
\[ E_\ast (\det) = E_\ast \otimes_{\pi_0 S^0} \pi_0 (E \wedge S(1)) \] is an isomorphism, and respects the \( G \)-action by the naturality of the spectral sequence. \qed

The following technical result is the key to our calculations.

**Proposition 3.6.** The \( G \)-spectrum \( E \wedge S(1) \) has the structure of a \( K \)-local continuous \( G \)-spectrum.

Proof. As in (2.3) we need to construct an augmented cosimplicial \( G \)-spectrum
\[ E \wedge S(1) \rightarrow F_c((G \wedge S^0)^+ \wedge S^0(1)) \]
so that the augmentation refines the \( G \)-action on \( E \wedge S(1) \).

As above, we continue writing \( S/p^k \) for \( EG^{+} \wedge \tilde{S} \) with its \( G/G^{+} \) action. Let us also write \( S/p^k \) for the Moore spectrum when we do not need to refer to the action.

Since \( M_{J(i)} \) and \( S/p^k \) are finite spectra we have
\[ F_c((G \wedge S^0)^+ \wedge S^0(1)) = \text{holim}_i \text{hocolim}_j F_c((G \wedge S^0)^+ \wedge S^0(1) \wedge M_{J(i)}); \]
indeed, both sides of the last equivalence are \( p \)-complete and the natural map between them is an equivalence after smashing with \( S/p^k \). For all \( j \) so that \( U_j \) is in the kernel of the diagonal action of \( G \) on \( E \wedge S^0 \), these assemble into the cosimplicial spectrum we need. \qed

We can now make our central definition.

**Definition 3.7.** The determinant sphere is the spectrum
\[ S(\det) = (E \wedge S(1))^{h \mathbb{G}} = \text{holim}_\Delta F_c((G^+)^{+1}, E \wedge S(1))^\mathbb{G}. \]

**Remark 3.8.** If \( \mathbb{K} \subseteq \mathbb{G} \) is closed we defined (Definition 2.5)
\[ (E \wedge S(1))^{h \mathbb{K}} = \text{holim}_\Delta F_c((G^+)^{+1}, E \wedge S(1))^\mathbb{K}. \]
Therefore, using Proposition 3.5 and Remark 2.9, we have a homotopy fixed point spectral sequence
\[ H_\ast (\mathbb{K}, E_\ast S(\det)) \Rightarrow \pi_{-s}(E \wedge S(1))^{h \mathbb{K}}. \]

We now must show that there is an isomorphism of Morava modules \( E_\ast S(\det) \cong E_\ast \langle \det \rangle \). But this follows directly from Proposition 3.5 and Corollary 2.18.

**Proposition 3.9.** There is an isomorphism of Morava modules
\[ E_\ast S(\det) \cong E_\ast \langle \det \rangle. \]
We now extend this map to an equivalence of spectra. Let \( \iota : S(\det) = (E \wedge S(1))^hG \to E \wedge S(1) \) be the inclusion of the fixed points from Lemma 2.11, and let \( \mu : E \wedge E \to E \) be the multiplication. Define

\[
f : E \wedge S(\det) \to E \wedge S(1)
\]

to be the composition

\[
(3.1) \quad E \wedge S(\det) \xrightarrow{1 \wedge \iota} E \wedge E \wedge S(1) \xrightarrow{\mu \wedge 1} E \wedge S(1).
\]

This map is \( G \)-equivariant if we use the action on \( E \) on the source and the diagonal action on the target.

**Theorem 3.10.** The map \( f : E \wedge S(\det) \to E \wedge S(1) \) of (3.1) is a \( G \)-equivariant equivalence and induces the isomorphism of Morava modules

\[
E_*S(\det) \cong E_*S(1).
\]

of Proposition 3.9.

**Proof.** To check that \( f \) is an equivalence we need only check that it induces the indicated map on Morava modules. Applying \( \pi_*(-) \) to (3.1) gives

\[
(3.2) \quad E_*S(\det) \xrightarrow{\cong} E_*(E \wedge S(1)) \xrightarrow{\cong} E_*S(1)
\]

\[
\cong \quad \Map^c(G, E_*(S(1)))^G \xrightarrow{\cong} \Map^c(G, E_*S(1)) \xrightarrow{\cong} E_*S(1).
\]

The first vertical isomorphism is from Corollary 2.18, whereas the second is the isomorphism of Lemma 2.14. In the bottom row, the first map is the inclusion of fixed points and the second map is evaluation at the unit \( e \in G \). The fixed points on the bottom left are exactly the constant functions, so the composite is an isomorphism as claimed. \( \square \)

This yields the following practical invariance result.

**Corollary 3.11.** If \( K \) is a closed subgroup of \( G \) which is in the kernel of the determinant, then \( E^hK \wedge S(\det) \cong E^hK \).

**Proof.** We use Theorem 3.10. When we restrict the \( G \)-action on the Tate sphere \( S(1) \) to \( K \), we get that \( K \) acts trivially, so \( S(1) \) is \( K \)-equivariantly equivalent to \( S^0 \). We have

\[
E^hK \wedge S(\det) \cong (E \wedge S(\det))^hK \cong (E \wedge S(1))^hK \cong E^hK,
\]

where the first equivalence follows since \( S(\det) \) is a \( K \)-locally dualizable spectrum with trivial \( K \)-action. \( \square \)

**Remark 3.12.** The specifics of the determinant homomorphism are not relevant for this construction and its immediate properties. Indeed, for any continuous homomorphism \( \phi : G \to \mathbb{Z}_p^\times \), we may define a \( K \)-local \( \phi \)-twisted sphere by the formula

\[
S(\phi) = (E \wedge S(1))^hG,
\]

where on the right hand side \( G \) acts diagonally, and through \( \phi \) on \( S(1) \). The proof of Proposition 3.9 generalizes to compute the corresponding Morava module as

\[
E_*S(\phi) \cong E_*\phi,
\]
where the right hand side denotes the action on $E_\ast$ obtained by twisting the standard action with $\phi$. This construction amounts to giving the dashed lift as indicated in the following diagram involving the group $\text{Pic}_{n}^0$ of $K$-local spectra $X$ with $E_\ast X \cong E_\ast$ and the algebraic Picard group $(\text{Pic}_{n}^0)_{\text{alg}}$ of invertible $G$-$E_0$-modules:

$$
\begin{array}{ccc}
\text{Pic}_{n}^0 & \longrightarrow & (\text{Pic}_{n}^0)_{\text{alg}} \cong H^1_c(G, E_0^\times) \\
\downarrow & & \downarrow \\
H^1_c(G, Z_p^\times) & \longrightarrow & H^1_c(G, E_0^\times).
\end{array}
$$

The bottom horizontal map is induced by the inclusion $Z_p^\times \rightarrow E_0^\times$.

We note that the determinant homomorphism topologically generates most of the image of the depicted horizontal arrow, so we are not losing much information by restricting our attention to its study. In particular, Westerland’s version of the determinant [Wes17] and ours have the same image in the algebraic Picard group. Indeed, they agree on $S \subseteq G$ and the map from $H^1_c(G, Z_p^\times)$ to $(\text{Pic}_{n}^0)_{\text{alg}}$ factors through $H^1_c(S, \mathcal{W}_p^\times) \cong H^1_c(S, \mathcal{W}_p^\times)^{\text{Gal}}$.

4. Deconstructing the determinant sphere

Let $SG \subseteq G$ be the kernel of the determinant. Then we can form the fixed point spectrum $E^{hSG}$. This will have a residual action of $G/SG \cong Z_p^\times$. (See the paragraph before Theorem 4 in [DH04].) Furthermore

$$(E \wedge S(1))^{hSG} \cong E^{hSG} \wedge S(1),$$

where the right hand side has a diagonal $Z_p^\times$-action.

At odd primes we get a simple description of $S(\det)$ directly from Devinatz–Hopkins fixed point theory.

**Proposition 4.1.** Let $p > 2$ and let $\phi \in G$ be any element so that $\det(\phi)$ topologically generates $Z_p^\times$. Then there is a fiber sequence

$$S(\det) \longrightarrow E^{hSG} \longrightarrow E^{hSG} \wedge S(1).$$

**Proof.** By construction, the action of $g \in G$ on $S(1)$ is given, up to homotopy, by multiplication by $\det(g) \in Z_p^\times$. Thus, the diagonal action of $\phi$ on $E^{hSG} \wedge S(1)$ is, up to homotopy, given by

$$\phi \wedge \det(\phi) : E^{hSG} \wedge S(1) \longrightarrow E^{hSG} \wedge S(1).$$

Using that $S(1)$ is non-equivariantly the sphere $S^0$, we have a homotopy commutative diagram

$$
\begin{array}{ccc}
E^{hSG} \wedge S(1) & \longrightarrow & E^{hSG} \wedge S(1) \\
\downarrow & \phi \wedge \det(\phi) \downarrow & \phi \wedge \det(\phi) \downarrow \\
E^{hSG} & \longrightarrow & E^{hSG}.
\end{array}
$$

Let $F$ be fiber of the bottom map. The composition

$$S(\det) = (E \wedge S(1))^{hG} \longrightarrow E^{hSG} \wedge S(1) \xrightarrow{\phi \wedge \det(\phi) \wedge \phi^{-1}} E^{hSG} \wedge S(1).$$
is null-homotopic, so we get a map \( f: S(\det) \to F \). Using the fact that 
\[
E_\ast E^{hSG} \cong \text{Map}^c(G/SG, E_\ast) \cong \text{Map}^c(Z_p^\times, E_\ast)
\]
we compute that \( f \) induces an isomorphism of Morava modules. \( \square \)

We can refine the fiber sequence of Proposition 4.1. We still have \( p > 2 \) and we have a splitting
\[
\mu \times (1 + p\mathbb{Z}_p) \cong \mathbb{Z}_p^\times.
\]
The group \( \mu \cong \mathbb{F}_p^\times \) is cyclic of order \( p - 1 \) and \((1 + p\mathbb{Z}_p)\) is isomorphic to \( \mathbb{Z}_p \) itself.

Let \( \alpha \in \mathbb{W}^\times \subseteq G \) be a primitive \((p^n - 1)\)st root of unity; then \( \det(\alpha) \in \mu \) is a generator. The group \( \mu \subseteq \mathbb{Z}_p^\times \) acts on \( E^{hSG} \) and, since this group is abstractly isomorphic to \( C_p \), the spectrum \( E^{hSG} \) splits as a wedge of the eingenspectra for this action. Let \( E^{hSG}_\chi \) be the summand defined by the equations
\[
\pi_*E^{hSG}_{\chi} = \{ x \in \pi_*E^{hSG} \mid \alpha x = \det(\alpha)^{-1} x \}.
\]
Note that the spectrum \( E^{hSG}_\chi \) corresponds to \((E^{hSG} \wedge S(1))^\mu \). Indeed, forgetting the \( \mu \)-action and remembering that the underlying spectrum of \( S(1) \) is the \( p \)-complete sphere, the map which sends \( x \in \pi_*E^{hSG} \) to \( x \wedge 1 \in \pi_*\left( E^{hSG} \wedge S(1) \right) \) is a non-equivariant isomorphism. Now note that if \( \alpha \cdot x = \det(\alpha)^{-1} x \) in \( \pi_*E^{hSG} \) then \( \alpha \cdot (x \wedge 1) = \alpha x \wedge \det(\alpha) = x \wedge 1 \) in \( \pi_*\left( E^{hSG} \wedge S(1) \right) \) so that
\[
x \wedge 1 \in \left( \pi_*\left( E^{hSG} \wedge S(1) \right) \right)^\mu \cong \pi_*\left( E^{hSG} \wedge S(1) \right)^\mu.
\]

**Proposition 4.2.** Let \( p > 2 \) and let \( \psi \in G \) be any element so that \( \det(\psi) \) topologically generates \( 1 + p\mathbb{Z}_p \subseteq \mathbb{Z}_p^\times \). Then there is a fiber sequence
\[
S(\det) \xrightarrow{\det(\psi)^{-1}} E^{hSG}_\chi \xrightarrow{\det(\psi)^{-1}} E^{hSG}.
\]

The proof is very similar to that of Proposition 4.1. This fiber sequence appears in [GHMR15, Rem. 2.5] although there is a typo there: the factor of \( \det(\psi^{p+1}) \) should be replaced by \( \det(\psi)^{-(p+1)} \) in Equation (2.6).

At the prime 2 we have \( Z_2^\times \cong \mu \times (1 + 4\mathbb{Z}_2) \) for \( \mu = \{ \pm 1 \} \) and the decomposition is more subtle. In particular, \( E^{hSG} \) does not decompose as a wedge of \( \mu \)-eigenspectra, where \( \mu \) acts on \( E^{hSG} \) through \( Z_2^\times \cong G/SG \). Thus we need a replacement. The following construction expands on ideas of Hans-Werner Henn.

It follows from its construction in Proposition 3.1 that, as a \( \mu \)-spectrum, \( S(1) \) is \( S^{\sigma - 1} \) where \( \sigma \) is the one-dimensional sign representation of \( \mu \). We have a fiber sequence of \( \mu \)-spectra
\[
S^{\sigma - 1} \to S^0 \wedge \mu_+ \to S^0
\]
where \( S^0 \) has the trivial action. This is a fiber sequence of \( Z_2^\times \)-spectra by restriction along the quotient map \( Z_2^\times \to \mu_+ \) with kernel \( 1 + 4\mathbb{Z}_2 \).

We smash this sequence with \( E^{hSG} \) and use the diagonal action to obtain a fiber sequence of \( Z_2^\times \)-spectra
\[
E^{hSG} \wedge S^{\sigma - 1} \to E^{hSG} \wedge \mu_+ \to E^{hSG}.
\]

Now take \( \mu \)-homotopy fixed points to get a fiber sequence of \( Z_2 \cong Z_2^\times / \mu \)-spectra. We give a special name to the fiber, i.e., we denote by \( E^{hSG}_- \) the spectrum
\[
E^{hSG}_- = (E^{hSG} \wedge S^{\sigma - 1})^\mu.
\]
where $\mu$ acts diagonally on the right-hand side. Thus, we have the fiber sequence

\[(4.1)\]

\[E^{hSG} \rightarrow E^{hSG} \xrightarrow{\text{tr}} (E^{hSG})^{h\mu},\]

where $\text{tr}$ is the transfer.

Now let $\psi \in G$ is any element so that $\det(\psi)$ topologically generates $1 + 4\mathbb{Z}_2$.

Since (4.1) is a cofiber sequence of $\mathbb{Z} \times \mathbb{Z}_2$-$\text{spectra}$ there is an extension of the map $\psi: E^{hSG} \rightarrow E^{hSG}$ to a commutative diagram

\[
\begin{array}{ccc}
E^{hSG} & \longrightarrow & E^{hSG} \\
\downarrow & & \downarrow \\
E^{hSG} & \longrightarrow & E^{hSG}
\end{array}
\]

Proposition 4.3. Let $p = 2$. Then there is a fiber sequence

\[S(\langle \det \rangle) \longrightarrow E^{hSG}_{\langle \det \rangle} \xrightarrow{\psi^{-1}} E^{hSG}_{\langle \det \rangle}.\]

Proof. The argument is essentially the same as in Proposition 4.1. Here is more detail. By construction

\[S(\langle \det \rangle) = (E \wedge S(1))^{hG} \simeq (E^{hSG} \wedge S(1))^{h\mathbb{Z}_2}.\]

Using the decomposition $\mathbb{Z}_2^\times = (1 + 4\mathbb{Z}_2) \times \mu$ we obtain a fiber sequence

\[S(\langle \det \rangle) \longrightarrow (E^{hSG} \wedge S(1))^{h\mu} \xrightarrow{(\psi \wedge \det(\psi) - 1)^{h\mu}} (E^{hSG} \wedge S(1))^{h\mu}.\]

Here we are again using that, up to homotopy, $g \in G$, acts on $S(1) = S^0$ by multiplication by $\det(g)$. Since $E^{hSG} \wedge S(1) \simeq E^{hSG} \wedge S^{\sigma-1}$ as $\mu$-$\text{spectra}$, we have a commutative diagram

\[
\begin{array}{ccc}
(E^{hSG} \wedge S(1))^{h\mu} & \longrightarrow & (E^{hSG} \wedge S(1))^{h\mu} \\
\downarrow \simeq & & \downarrow \simeq \\
E^{hSG}_{\langle \det \rangle} & \longrightarrow & E^{hSG}_{\langle \det \rangle}
\end{array}
\]

The result follows. \(\Box\)

Example 4.4. At height 1, the determinant map $G \rightarrow \mathbb{Z}_2^{\times}$ is the identity. We can also choose $E = K$, the $p$-completion on complex theory. We have that

\[K_pS^2 \simeq K_p\langle \det \rangle\]

so the $K$-localization of $S^2$ is a valid model for the determinant sphere. If $p > 2$, this must be the same as ours, but at $p = 2$ there is a possibility that $S(\langle \det \rangle) \simeq S^2 \wedge P$, where $P = DQ$ is the dual of the ‘question mark complex’. By [HMS94], $P$ is the unique element in the $K$-local Picard group so that $K_pP \simeq K_pS^0$ as $\mathbb{Z}_2^{\times}$-modules but $KO \wedge P \simeq \Sigma^4KO$. This possibility turns out to be the case.

To see this, we observe that $KO = K_{h\mu}$. We can use Theorem 3.10 to deduce that $\mathbb{Z}_2^{\times}$-equivariantly, and therefore $\mu$-equivariantly, we have an equivalence $K \wedge S(\langle \det \rangle) \simeq K \wedge S(1)$, where the action on the right hand side is diagonal. As
mentioned above, \(\mu\)-equivariantly \(S(1)\) is the representation sphere \(S^{\sigma-1}\), so we conclude that
\[
(K \wedge S(\det))^{h\mu} \simeq (K \wedge S^{\sigma-1})^{h\mu}.
\]
By Proposition 2.17, we get that the left-hand side is \(KO \wedge S(\det)\). For the right-hand side, we can use the \(\mu\)-equivariant Bott periodicity equivalence \(K \wedge S^{\sigma+1} \simeq K\) to conclude, altogether, that
\[
KO \wedge S(\det) \simeq (K \wedge S^{-2})^{h\mu} \simeq \Sigma^{-2}KO.
\]
Thus \(S(\det) \simeq S^2 \wedge P\).

Note that in this case we have shown that \(E^{hBG}_\bullet = \Sigma^{-2}KO\), and the fiber sequence of Proposition 4.3 is a shifted version of that given by \(P\) in [GHMR15, Ex. 5.1].
