Abstract. Bouncing scenarios offer an alternative to the inflationary paradigm for the generation of perturbations in the early universe. Recently, there has been a surge in interest in examining the issue of primordial magnetogenesis in the context of bouncing universes. As in the case of inflation, the conformal invariance of the electromagnetic action needs to be broken in bouncing scenarios in order to generate primordial magnetic fields which correspond to observed strengths today. The non-minimal coupling, which typically depends on a scalar field that possibly drives the homogeneous background, leads to a cross-correlation at the level of the three-point function between the perturbation in the scalar field and the magnetic fields. This has been studied in some detail in the context of inflation and, specifically, it has been established that the three-point function satisfies the so-called consistency relation in the squeezed limit. In this work, we study the cross-correlation between the magnetic fields and the perturbation in an auxiliary scalar field in a certain class of bouncing scenarios. We consider couplings that lead to scale invariant spectra of the magnetic field and evaluate the corresponding cross-correlation between the magnetic field and the perturbation in the scalar field. We find that, when compared to de Sitter inflation, the dimensionless non-Gaussianity parameter that characterizes the amplitude of the cross-correlations proves to be considerably larger in bouncing scenarios. We also show that the aforementioned consistency condition governing the cross-correlation is violated in the bouncing models. We discuss the implications of our results.

Keywords: alternatives to inflation, inflation, non-gaussianity, primordial magnetic fields

ArXiv ePrint: 1807.05530
1 Introduction

Magnetic fields permeate the universe over a wide range of scales. In addition to the detection of magnetic fields in astrophysical systems such as stars and galaxies, recent observations also point towards the prevalence of these fields on cosmological scales, viz. in the large scale structures [1–6] and even in the intergalactic medium [7, 8]. In galaxies and clusters of galaxies, the strengths of the magnetic fields have been measured to be a few micro Gauss, while in the intergalactic medium, they are estimated to be of the order of $10^{-17}$ Gauss at 1 Mpc [7–16]. In contrast, using CMB observations by Planck and POLARBEAR, the upper bound on the magnetic fields has been arrived at to be about a few nano Gauss [17, 18], which has also been corroborated by the upper limits obtained from the NRAO VLA Sky Survey [19]. It is well known that certain astrophysical processes, particularly the dynamo mechanism, can, in the presence of a seed field, augment the strength of the magnetic fields in galaxies. The origin of such progenitor fields is usually attributed to primordial processes.

Inflation is presently the most widely accepted paradigm to explain the generation and evolution of perturbations in the early universe. The issue of magnetogenesis, viz. the origin of magnetic fields, has been widely studied in various inflationary scenarios and, by means of the breaking of conformal invariance of the electromagnetic field, it has been possible to obtain scale invariant magnetic fields of the relevant strengths over the correlation scales of interest [20–38]. Nevertheless, such models are known to be afflicted by the backreaction and
strong coupling problems [23, 39, 40]. Consequently, it seems worthwhile to investigate the
generation of magnetic fields in scenarios that provide a feasible alternative to the inflationary
framework. Among such alternatives, the most popular ones are the so-called bouncing
models [41–61]. In these models, the universe goes through a period of contraction followed
by an expanding phase, with a ‘bounce’ connecting the two epochs. Lately, there have
been some efforts towards understanding the generation of magnetic fields in the bouncing
scenarios [62–68].

In a recent work [65], we had analytically illustrated how scale invariant magnetic fields
can be produced in a certain sub-class of symmetric bouncing scenarios. Using these analyti-
cal solutions, it would be interesting to examine the cross-correlations of these magnetic fields
with scalar perturbations present in the bouncing scenarios. These correlations have been
examined before in the context of inflation [69–73]. The magnitude of the non-Gaussianities
generated through such correlations has been estimated to be quite large for inflation, and
the shape of the non-Gaussianities peaks in the flattened limit, i.e. when the wavenumber
of the scalar perturbation is twice the wavenumber associated with the two modes of the
magnetic field. In this work, we study the cross-correlations of the magnetic fields produced
in bouncing universes with the perturbations in an auxiliary scalar field. Ideally, it would
be more appropriate to evaluate the cross-correlation between the primordial magnetic fields
and the curvature perturbation. However, as is well known, examining the behavior of the
curvature perturbations in bouncing models necessitates considerable modeling, often involv-
ing more than one field (see, for instance, ref. [74]). Therefore, it would be instructive to first
investigate the behavior of the cross-correlation of the magnetic fields with the perturbation
in an auxiliary scalar field and explore their ramifications.

One of the most important characteristics of three-point functions is their behavior
in the squeezed limit of the wavenumbers involved, i.e. when one of the wavenumbers is
assumed to be much smaller than the other two. In inflation, typically, the amplitude of the
mode with the longest wavelength and, therefore, the smallest wavenumber, freezes on super-
Hubble scales. Therefore, in the squeezed limit, the three-point function can be completely
expressed in terms of the two-point function through a relation referred to as the consistency
condition (see refs. [75–81] in the context of three-point functions involving scalar and tensor
perturbations, and refs. [71, 72] for cross-correlations between the scalar perturbation and
the magnetic fields). However, in the case of the bouncing models that we shall study, the amplitude of the scalar perturbations grows strongly as one approaches the bounce (in this
case, see refs. [74, 82]). This suggests that the consistency relation may not hold in such
scenarios (for a similar effect in the case of the tensor bispectrum, see ref. [82]). Therefore,
it is of utmost significance to examine whether the consistency relation, which holds true for
inflationary magnetogenesis, would be valid in the bouncing models.

This paper is organized as follows. In the following section, we shall describe a few
essential aspects concerning the evolution of the electromagnetic field in the presence of
non-minimal coupling. We shall also evaluate the power spectra of the magnetic fields that
arise in inflationary as well as bouncing scenarios in the presence of a non-minimal, power
law coupling that is often considered in this context. In section 3, after briefly revisiting
the calculation of the cross-correlations between the perturbation in the scalar field and the
magnetic fields in the context of inflation, we shall evaluate the corresponding three-point
function in the matter bounce scenario of our interest. In section 4, we shall define a dimen-
sionless non-Gaussianity parameter to characterize the three-point function and calculate
the parameter in both the inflationary and bouncing models. In section 5, we shall evaluate
the cross-correlation in the squeezed limit and illustrate that, while the consistency relation holds true in the case of inflation, it is violated in the bouncing scenario. Finally, we shall conclude with a brief discussion in section 6.

We shall work with natural units such that \( \hbar = c = 1 \), and set the Planck mass to be \( M_{\text{Pl}} = (8\pi G)^{-1/2} \). We shall adopt the metric signature of \((-++,++)\). Greek indices shall denote the spacetime coordinates, whereas the Latin indices shall represent the spatial coordinates, except for \( k \) which shall be reserved for denoting the wavenumber. Lastly, an overprime shall denote differentiation with respect to the conformal time coordinate.

2 Generation of scale invariant magnetic fields in the early universe

In this section, we shall describe the generation of primordial magnetic fields via a non-minimal coupling. We shall introduce the form of the electromagnetic action and, after choosing to work in a specific gauge, we shall obtain the equation of motion governing the electromagnetic vector potential. We shall quantize the vector potential in terms of the modes that satisfy the equation of motion in Fourier space. We shall also define the power spectrum corresponding to the energy density associated with the magnetic field. Thereafter, we shall consider a certain form of the coupling function wherein it can be expressed as a simple power of the scale factor, and analytically evaluate the magnetic power spectra in de Sitter inflation and in a specific class of bouncing scenarios.

2.1 Non-minimally coupled electromagnetic fields

We shall consider the background to be the spatially flat, Friedmann-Lemaître-Robertson-Walker (FLRW) metric that is described by the line-element

\[
ds^2 = a^2(\eta) \left( -d\eta^2 + \delta_{ij} dx^i dx^j \right),
\]

where \( a(\eta) \) is the scale factor and \( \eta \) denotes the conformal time coordinate. We shall consider the action

\[
S_{\text{em}}[A^\mu, \phi] = -\frac{1}{16\pi} \int d^4 x \sqrt{-g} J^2(\phi) F_{\mu\nu} F^{\mu\nu},
\]

where the electromagnetic field tensor \( F_{\mu\nu} \) is given in terms of the vector potential \( A^\mu \) by the relation

\[
F_{\mu\nu} = \partial_\mu A_\nu - \partial_\nu A_\mu.
\]

The quantity \( J(\phi) \) describes the non-minimal coupling, with \( \phi \) denoting a scalar field that possibly contributes to the background evolution. We shall assume that there is no homogeneous component to the electromagnetic field. We shall choose to work in the Coulomb gauge wherein \( A_0 = 0 \) and \( \partial_i A^i = 0 \). In such a gauge, at the quadratic order in the inhomogeneous modes, the action describing the electromagnetic field is found to be (see, for example, refs. [24, 27])

\[
S[A_i] = \frac{1}{4\pi} \int d\eta \int d^3 x \left\{ J^2(\phi) \left[ \frac{1}{2} A_i'^2 - \frac{1}{4} (\partial_i A_j - \partial_j A_i)^2 \right] \right\}.
\]

We can vary this action to arrive at the following equation of motion for the electromagnetic vector potential:

\[
A_i'' + 2 \frac{J'}{J} A_i' - \nabla^2 A_i = 0.
\]
For each comoving wavevector $k$, we can define the right-handed orthonormal basis $(\varepsilon_{k1}, \varepsilon_{k2}, \hat{k})$, where

$$|\varepsilon_k|^2 = 1, \quad \varepsilon_{k1} \times \varepsilon_{k2} = \hat{k} \quad \text{and} \quad \varepsilon_{k1} \cdot \varepsilon_{k2} = \hat{k} \cdot \varepsilon_{k1} = \hat{k} \cdot \varepsilon_{k2} = 0. \quad (2.6)$$

On quantization, the vector potential $\hat{A}_i$ can be Fourier decomposed as follows [24, 27]:

$$\hat{A}_i(\eta, x) = \sqrt{4\pi} \int \frac{d^3 k}{(2\pi)^{3/2}} \sum_{\lambda=1}^2 \varepsilon_{\lambda i} \left[ \hat{b}_{\lambda k}^\dagger \bar{A}_{\lambda k}(\eta) e^{ik \cdot x} + \hat{b}_{\lambda k} \bar{A}_{\lambda k}^*(\eta) e^{-ik \cdot x} \right], \quad (2.7)$$

where the Fourier modes $\bar{A}_k$ satisfy the differential equation

$$\bar{A}_k'' + \frac{2J'}{J} \bar{A}_k + k^2 \bar{A}_k = 0. \quad (2.8)$$

The quantities $\varepsilon_{\lambda i}$ represent the polarization vectors and the summation corresponds to the two orthonormal transverse polarizations. The operators $\hat{b}_{\lambda k}$ and $\hat{b}_{\lambda k}^\dagger$ are the annihilation and creation operators satisfying the following standard commutation relations:

$$[\hat{b}_{\lambda k}, \hat{b}_{\lambda' k'}^\dagger] = [\hat{b}_{\lambda k}^\dagger, \hat{b}_{\lambda' k'}] = 0, \quad [\hat{b}_{\lambda k}, \hat{b}_{\lambda' k'}] = \delta^{(3)}(k - k') \delta_{\lambda \lambda'}. \quad (2.9)$$

Let us now define a new variable $\mathcal{A}_k = J \bar{A}_k$, which, as we shall see, proves to be convenient to deal with. In terms of the new variable, eq. (2.8) for $\bar{A}_k$ simplifies to

$$\mathcal{A}_k'' + \left( k^2 - \frac{J''}{J} \right) \mathcal{A}_k = 0. \quad (2.10)$$

2.2 Power spectra

Since we shall be focusing only on the properties of the magnetic field and not those of the electric field, let us attend to the power spectra of the generated magnetic fields. Let $\hat{\rho}_B$ denote the operator corresponding to the energy density associated with the magnetic field. Upon using the decomposition (2.7) of the vector potential, the expectation values of the energy density $\hat{\rho}_B$ can be evaluated in the vacuum state, say, $|0\rangle$, that is annihilated by the operator $\hat{b}_{\lambda k}$ for all $k$ and $\lambda$. It can be shown that the spectral energy density of the magnetic field can be expressed in terms of the modes $\bar{A}_k$ and $\mathcal{A}_k$ and the coupling function $J$ as follows [24, 27]:

$$P_B(k) = \frac{d}{d \ln k} \left. \frac{d}{d \ln k} \right|_{\eta=0} = \frac{J^2(\eta)}{2\pi^2} \frac{k^5}{a^4(\eta)} |\bar{A}_k(\eta)|^2 = \frac{1}{2\pi^2} \frac{k^5}{a^4(\eta)} |\mathcal{A}_k(\eta)|^2. \quad (2.11)$$

The spectral energy density $P_B(k)$ is often referred to as the power spectrum of the generated magnetic fields. A flat or scale invariant magnetic field spectrum corresponds to a constant, i.e. $k$-independent, $P_B(k)$.

2.3 The inflationary case

Let us first consider the simple case of de Sitter inflation, wherein the scale factor is given by

$$a(\eta) = \frac{1}{H_0 \eta}, \quad (2.12)$$

$$P_B(k) = \frac{1}{2\pi^2} \frac{k^5}{a^4(\eta)} |\mathcal{A}_k(\eta)|^2. \quad (2.11)$$

The spectral energy density $P_B(k)$ is often referred to as the power spectrum of the generated magnetic fields. A flat or scale invariant magnetic field spectrum corresponds to a constant, i.e. $k$-independent, $P_B(k)$.
with $H_0$ being the value of the Hubble parameter during inflation. In order to solve for the electromagnetic modes, we need to choose a form of the coupling function. In keeping with the expressions for the coupling functions that have been adopted earlier [24, 27, 69–72], we shall work with a coupling function that can be written as a simple power of the scale factor as follows:

$$ J(\eta) = J_0 \left[a(\eta)\right]^n = \frac{J_0}{(-H_0 \eta)^n}. \quad (2.13) $$

We shall set $J_0 = (-H_0 \eta_c)^n$, where $\eta_c$ denotes the conformal time at the end of inflation. This choice ensures that $J$ reduces to unity at $\eta_c$. For such a coupling function, $J''/J = n (n+1)/\eta^2$ and the solutions to eq. (2.10) can then be expressed as [6, 24]:

$$ A_k(\eta) = \sqrt{-k \eta} \left[C_1(k) J_{n+1/2}(-k \eta) + C_2(k) J_{-n-1/2}(-k \eta) \right], \quad (2.14) $$

where $J_n(x)$ refers to the Bessel function and the coefficients $C_1(k)$ and $C_2(k)$ can be fixed from the standard Bunch-Davies initial conditions to be

$$ C_1(k) = \sqrt{\frac{\pi}{4k}} e^{-i(n-1)\pi/2} \cos(n\pi), \quad C_2(k) = \sqrt{\frac{\pi}{4k}} e^{i\pi/2} \cos(n\pi). \quad (2.15) $$

We should emphasize here that the initial conditions are imposed in the domain wherein $k^2 \gg J''/J$, which, for the simple cases of de Sitter inflation and a power law coupling [cf. eq. (2.13)], roughly corresponds to the modes being well inside the Hubble radius. It is useful to note that the mode $A_k$ can be expressed conveniently in terms of the Hankel function of the first kind $H^{(1)}_n(x)$ as

$$ \tilde{A}_k(\eta) = \frac{1}{J(\eta)} \sqrt{\frac{\pi \eta}{4}} e^{i(n+1)\pi/2} H^{(1)}_{n+1/2}(-k \eta), \quad (2.16) $$

with $J(\eta)$ given by eq. (2.13).

Using the above expression for the modes and the definition (2.11), the power spectrum for the magnetic field can be obtained to be

$$ P_B(k) = \frac{H_0^4}{8\pi} (-k \eta_c)^5 \left|H^{(1)}_{n+1/2}(-k \eta_c)\right|^2, \quad (2.17) $$

For $n > -1/2$, at late times (i.e. as $\eta_c \to 0$), this expression reduces to

$$ P_B(k) = \frac{H_0^4}{8\pi^3} \left[2^{2n+1} \Gamma \left(\frac{1}{2} + n\right)^2 \right] (-k \eta_c)^{4-2n}. \quad (2.18) $$

Therefore, the spectral index characterizing the power spectrum of the magnetic field is given by $n_B = 4 - 2n$. Clearly, we must have $n = 2$ in order to obtain a scale invariant power spectrum. On the other hand, for $n < -1/2$, at late times (i.e. as $\eta_c \to 0$), the power spectrum can be obtained to be

$$ P_B(k) = \frac{H_0^4}{8\pi^3} \left[2^{-2n-1} \Gamma \left(-\frac{1}{2} - n\right)^2 \right] (-k \eta_c)^{6+2n}. \quad (2.19) $$

In this case, the spectral index of the magnetic field power spectrum is given by $n_B = 6 + 2n$. Therefore, a scale invariant power spectrum can also be obtained for $n = -3$. However, the cases wherein $n < 0$ lead to severe backreaction issues which result in the termination of inflation within about 10 e-folds [69, 72]. Therefore, we shall avoid such scenarios in this work. Also, note that, when $n_B = 0$, the amplitude of the power spectrum is determined only by the value of $H_0$. One finds that, in order to obtain magnetic fields of nano Gauss strength today, the value of $H_0$ should be of the order of $10^{13}$ GeV [69].
2.4 The bouncing scenarios

We shall now discuss the generation of magnetic fields in bouncing scenarios. Let us assume that the non-singular bouncing scenario of our interest is described by the following form of the scale factor \( a(\eta) \) (in this context, see refs. [64, 74, 82]):

\[
a(\eta) = a_0 \left( 1 + \frac{\eta^2}{\eta_0^2} \right)^q = a_0 \left( 1 + k_0^2 \eta^2 \right)^q,
\]

where \( a_0 \) is the minimum value of the scale factor attained at the bounce (i.e. at \( \eta = 0 \)), \( \eta_0 = 1/k_0 \) denotes the time scale of the duration of the bounce and \( q > 0 \). It is evident that, for the case \( q = 1 \), during very early times wherein \( \eta \ll -\eta_0 \), the scale factor behaves as \( a \propto \eta^2 \), which corresponds to the behavior of the scale factor in a matter dominated universe. Therefore, the \( q = 1 \) case is often referred to as the matter bounce scenario. Later, when calculating the three-point function of interest, we shall restrict ourselves to the case of the matter bounce, but for now let us consider an arbitrary \( q \). Evidently, we shall also be required to assume a form of the non-minimal coupling function \( J \). As in the case of inflation, we shall assume that the coupling function can be expressed as a power law of the scale factor as follows:

\[
J(\eta) = J_0 \left[ a(\eta) \right]^\bar{n} = J_0 a_0^{\bar{n}} \left( 1 + k_0^2 \eta^2 \right)^{\bar{n} q},
\]

where \( J_0 \) is a suitable constant. We shall comment on the choice of \( J_0 \) in due course.

In order to solve the equation of motion governing the evolution of the electromagnetic mode in the matter bounce scenario, for convenience, we shall divide the time period of our interest into two domains, one far away from and prior to the bounce (i.e. \( -\infty < \eta < -\alpha \eta_0 \), with \( \alpha \gg 1 \)) and another around the bounce (i.e. \( -\alpha \eta_0 < \eta < \beta \eta_0 \), with \( \beta > 0 \)). We shall assume that \( \alpha \) is of the order of \( 10^5 \) and, as we shall explain later, we shall set \( \beta \) to be \( 10^2 \). During the first domain, the non-minimal coupling function \( J \) simplifies to a power law form: \( J(\eta) \propto \eta^{\bar{n}} \), where \( \bar{n} = 2 \bar{m} q \). Under these conditions, we have \( J''/J \approx \bar{\gamma} (\bar{\gamma} - 1)/\eta^2 \), which is of the same form as in the inflationary case that we had discussed in the previous sub-section. Therefore, in the first domain, we can express the electromagnetic modes \( \tilde{A}_k \) in terms of the Hankel function \( H^{(1)}_\gamma(x) \) as follows [64, 65]:

\[
\tilde{A}_k(\eta) \approx \frac{1}{J(\eta)} \sqrt{-\frac{\pi \eta}{4}} e^{i \bar{\gamma} \pi/2} H^{(1)}_{\bar{\gamma} - 1/2}(-k\eta),
\]

with \( J(\eta) \simeq J_0 a_0^{\bar{n}} (k \eta)^{\bar{m}} \). We should emphasize again that this solution has been constructed assuming that the Bunch-Davies initial conditions are imposed on the modes when \( k^2 > J''/J \). As we have clarified in the context of inflation, for the form of the coupling function we are working with [cf. eq. (2.21)], this condition again corresponds to the modes of interest being well inside the Hubble radius.

Let us now evaluate the power spectra of the magnetic fields as one approaches the bounce, in fact as \( k \eta \rightarrow 0^{+} \). Since the solution (2.22) is assumed to be applicable only in the first domain (i.e. over \( -\infty < \eta < -\alpha \eta_0 \)), we need to restrict ourselves to wavenumbers such that \( k \ll k_0/\alpha \). The power spectra of the magnetic fields for such modes can be written as [64, 65]

\[
\mathcal{P}_n(k) \approx \frac{\mathcal{F}(m)}{2 \pi^2} \left( \frac{H}{2 q} \right)^4 (-k \eta)^{4+2m},
\]

\[ \text{JCAP01(2019)048} \]
where $H \simeq (2q/a_0 \eta)(\eta_0/\eta)^2q$, while $m = \bar{\gamma}$ for $\bar{\gamma} \leq 1/2$ and $m = 1 - \bar{\gamma}$ for $\bar{\gamma} \geq 1/2$. The quantity $\mathcal{F}(m)$ is given by

$$\mathcal{F}(m) = \frac{\pi}{2^{m+1} \Gamma^2(m+1/2) \cos^2(\pi m)}. \quad (2.24)$$

Evidently the value of the index $m = -2$, which corresponds to either $\bar{\gamma} = 3$ or $\bar{\gamma} = -2$, leads to a scale invariant spectrum for the magnetic field.

The power spectrum (2.23) has been calculated before the bounce. We need to evolve the modes across the bounce and evaluate the power spectrum of the magnetic field after the bounce. In order for the problem to be tractable analytically, we shall hereafter restrict our analysis to the cases wherein $\bar{n} > 0$ [65]. We find that for scales of cosmological interest such that $k \ll k_0$, $k^2 \ll J''/J$ around the bounce. Hence, near the bounce, we can neglect the $k^2$ term in eq. (2.8) to arrive at

$$\bar{A}_k'' + 2 \frac{J'}{J} \bar{A}_k' \simeq 0. \quad (2.25)$$

This equation can be integrated twice to yield [65]

$$\bar{A}_k(\eta) \simeq \bar{A}_k(\eta_*) + \bar{A}'_k(\eta_*) \frac{a_{2,2}^n(\eta_*)}{a_0^2} \left[ \eta \, 2F_1 \left( \frac{1}{2}, \bar{\gamma}; \frac{3}{2}; -\frac{\eta^2}{\eta_0^2} \right) - \eta_* \, 2F_1 \left( \frac{1}{2}, \bar{\gamma}; \frac{3}{2}; -\frac{\eta_*^2}{\eta_0^2} \right) \right] \quad (2.26)$$

where $2F_1(a, b; c; z)$ denotes the hypergeometric function (see, for instance, ref. [83]). We shall choose $\eta_* = -\alpha \eta_0$, which then permits us to use the solution (2.22) in first domain to determine $\bar{A}_k(\eta_*)$ and $\bar{A}'_k(\eta_*)$, and thereby arrive at the solution in the second domain.

Note that the solution (2.26) is valid only when $k^2 \ll J''/J$ and, evidently, the condition will fail at suitably late times after the bounce (just as it does prior to the bounce). Therefore, the solution has to be utilized to evaluate the power spectrum of the magnetic field in the domain of its validity. Moreover, the numerical analysis of the modes suggest that the analytical solutions that we have obtained would be invalidated well before the condition $k^2 = J''/J$ is satisfied after the bounce [64]. For these reasons, we shall choose to evaluate the power spectrum after the bounce at $\eta = \beta \eta_0$, with $\beta$ chosen to be about $10^2$. Interestingly, for the scale factor (2.20) we are working with, for, say, $q = 1$, the time $\eta = \beta \eta_0$ roughly corresponds to the time of reheating that follows the phase of inflation in the conventional hot big bang model [64]. Having explained the reasons behind our choice of $\beta$, this seems an ideal stage to mention the value of $J_0$ we shall work with. It is straightforward to show that the power spectrum of the magnetic field does not depend on $J_0$. However, as we shall see later, the three-point cross-correlation indeed depends on its value. We shall choose the value of $J_0$ such that $J(\beta \eta_0) = 1$. This ensures that we recover the standard electromagnetic coupling after the bounce at roughly the time when the universe is expected to transit to the radiation dominated era, just as is done in the context of inflation. We can now analytically evaluate the power spectrum after the bounce at $\eta = \beta \eta_0$. We find that the power spectrum of the magnetic field retains its scale dependence across the bounce [65]. In the scale invariant case corresponding to $\bar{\gamma} = 3$, the amplitude of the power spectrum for $k/(a_0 k_0) \ll 1$ can be determined to be

$$\mathcal{P}_m(k) \simeq \left( \frac{45}{16 \beta} \right)^2 \left( \frac{k_0}{a_0} \right)^4. \quad (2.27)$$

For instance, if we choose, $k_0/(a_0 M_{Pl}) \simeq 10^{-4}$, we find that the above spectrum will lead to magnetic fields of nano Gauss strengths today.
3 Cross-correlations between the scalar perturbation and magnetic field

As is evident from the results of the preceding section, it is possible to obtain scale invariant magnetic fields of the requisite strength both in the case of inflation as well as in bouncing scenarios. Therefore, the behavior of the two-point function of the primordial magnetic fields alone is not adequate to distinguish between the inflationary and bouncing scenarios. It would hence be of utmost importance to study the cross-correlations of these fields with other fields that are expected to exist in the early universe, particularly the scalar fields. In this section, we shall arrive at the expression for the three-point function involving the magnetic field and the perturbation in the scalar field which leads to the non-minimal coupling. We shall first revisit the case of de Sitter inflation, wherein we shall consider the perturbation in an auxiliary scalar field and evaluate the three-point function. Thereafter, we shall calculate the three-point function in the bouncing model of our interest. We shall analyze the three-point function in these scenarios for two cases – one which leads to a scale invariant power spectrum for the magnetic field and another which results in a blue-tilted power spectrum that scales as the square of the wavenumber involved. While the former is observationally relevant, the latter case involves simpler computations and we shall utilize it to illustrate certain points.

The Lagrangian at the third order involving the perturbation \( \delta \phi \) in the scalar field and the electromagnetic vector potential \( A_i \) can be easily obtained from the original action (2.2). The corresponding interaction Hamiltonian can be determined to be [69]

\[
H_{\text{int}} = \frac{1}{4\pi} \int d^3x J^i \frac{d\delta \phi}{d\phi} \left( \frac{A_i'}{M_{\text{Pl}}}^2 + \frac{1}{2} (\partial_i A_j - \partial_j A_i)^2 \right), \tag{3.1}
\]

where \( \delta \phi \) denotes the perturbation in the scalar field. The cross-correlation between the perturbation in the scalar field and the magnetic field in real space is defined as

\[
\left\langle \frac{\delta \phi(\eta, \mathbf{x})}{M_{\text{Pl}}} \tilde{B}^i(\eta, \mathbf{x}) \right\rangle = \int \frac{d^3k_1}{(2\pi)^{3/2}} \int \frac{d^3k_2}{(2\pi)^{3/2}} \int \frac{d^3k_3}{(2\pi)^{3/2}} \left\langle \frac{\delta \phi_{k_1}(\eta) B_{k_2}^i(\eta) B_{k_3}^i(\eta)}{M_{\text{Pl}}} \right\rangle e^{i(k_1 + k_2 + k_3) \cdot \mathbf{x}}, \tag{3.2}
\]

where the components \( B_i \) of the magnetic field are related to the vector potential \( A_i \) through the relation

\[
B_i = \frac{1}{a} \epsilon_{ijl} \partial_j A_l, \tag{3.3}
\]

while \( \delta \phi_k \) and \( B_k^i \) denote the Fourier modes associated with the perturbation in the scalar field and the \( i \)-th component of the magnetic field. According to the standard rules of perturbative quantum field theory, the cross-correlation between the perturbation in the scalar field and the magnetic field in Fourier space, evaluated at the end of inflation, is given by [69, 72]

\[
\left\langle \frac{\delta \phi_{k_1}(\eta_e)}{M_{\text{Pl}}} \tilde{B}_{k_2}^i(\eta_e) \tilde{B}_{k_3}^i(\eta_e) \right\rangle = -i \int_{\eta_i}^{\eta_f} \frac{d\eta}{\eta} \left\langle \left[ \frac{\delta \phi_{k_1}(\eta_e)}{M_{\text{Pl}}} \tilde{B}_{k_2}^i(\eta_e) \tilde{B}_{k_3}^i(\eta_e), \tilde{H}_{\text{int}}(\eta) \right] \right\rangle, \tag{3.4}
\]

where \( \tilde{H}_{\text{int}} \) is the operator associated with the Hamiltonian (3.1) and the square brackets indicates the commutator.
We have already discussed the quantization of the electromagnetic modes in the previous section. The perturbation in the scalar field can be quantized in terms of the corresponding Fourier modes, say, \( f_k \) as

\[
\delta \phi (\eta, x) = \int \frac{d^3 k}{(2\pi)^{3/2}} \left[ \hat{a}_k f_k(\eta) e^{i k \cdot x} + \hat{a}_k^\dagger f_k^*(\eta) e^{-i k \cdot x} \right],
\]

(3.5)

where the annihilation and creation operators \( \hat{a}_k \) and \( \hat{a}_k^\dagger \) satisfy the following standard commutation relations:

\[
[\hat{a}_k, \hat{a}_{k'}] = [\hat{a}_k^\dagger, \hat{a}_{k'}^\dagger] = 0, \quad [\hat{a}_k, \hat{a}_{k'}^\dagger] = \delta^{(3)}(k - k').
\]

(3.6)

As we shall see, in order to achieve the coupling functions (2.13) and (2.21), we shall assume that the canonical scalar field is governed by the linear potential in the case of inflation and is free in the case of the bounce. We should emphasize that the field \( \phi \) is actually an auxiliary scalar field that does not necessarily source the background. In both the cases of inflation and bounce, the perturbation in the scalar field \( \delta \phi \) is governed by the equation of motion

\[
\delta \phi'' + 2 \mathcal{H} \delta \phi' - \nabla^2 \delta \phi = 0,
\]

(3.7)

where \( \mathcal{H} = a' / a \) is the conformal Hubble parameter. The Fourier modes \( f_k \) therefore satisfy the differential equation

\[
f_k'' + 2 \mathcal{H} f_k' + k^2 f_k = 0.
\]

(3.8)

Let us now define

\[
\left\langle \delta \phi_{k_1}(\eta_e) M_{vi} \hat{B}_{k_2}(\eta_e) \hat{B}_{k_3}(\eta_e) \right\rangle \equiv (2\pi)^{-3/2} G_{\delta \phi BB}(k_1, k_2, k_3) \delta^{(3)}(k_1 + k_2 + k_3).
\]

(3.9)

Then, upon using the expression (3.4), along with the form of the interaction Hamiltonian (3.1) and Wick’s theorem that applies to the products of the operators \( \hat{A}_k \) and \( \delta \phi_k \), one can show that the quantity \( G_{\delta \phi BB}(k_1, k_2, k_3) \) can be expressed as

\[
G_{\delta \phi BB}(k_1, k_2, k_3) = \frac{8\pi}{M_{Pl}} \frac{f_{k_1}(\eta_e) A_{k_2}(\eta_e) A_{k_3}(\eta_e)}{a^2(\eta_e)} \left\{ 2(k_2 \cdot k_3) G_1(k_1, k_2, k_3) - \left[ \frac{(k_2 \cdot k_3)^2}{k_2 k_3} + k_2 k_3 \right] G_2(k_1, k_2, k_3) \right\} + \text{complex conjugate},
\]

(3.10)

where \( G_1(k_1, k_2, k_3) \) and \( G_2(k_1, k_2, k_3) \) are described by the integrals

\[
G_1(k_1, k_2, k_3) = i \int_{\eta_i}^{\eta_f} d\eta \frac{dJ}{d\phi} f_{k_1}(\eta) \hat{A}_{k_2}^\dagger(\eta) \hat{A}_{k_3}^\dagger(\eta),
\]

(3.11a)

\[
G_2(k_1, k_2, k_3) = i k_2 k_3 \int_{\eta_i}^{\eta_f} d\eta \frac{dJ}{d\phi} f_{k_1}(\eta) \hat{A}_{k_2}^\dagger(\eta) \hat{A}_{k_3}^\dagger(\eta).
\]

(3.11b)

Given the solutions for the electromagnetic modes \( \hat{A}_k \) and the scalar perturbations \( f_k \) [cf. eqs. (2.8) and (3.8)], the above integrals can be evaluated in the inflationary and bouncing scenarios to arrive at the three-point function \( G_{\delta \phi BB}(k_1, k_2, k_3) \).
3.1 The three-point function in de Sitter inflation

Before we go on to evaluate the three-point function in the bouncing scenario, we shall first revisit its calculation in inflation in order to illustrate a few points. In section 2, when we had considered the evolution of the electromagnetic modes, for simplicity, we had assumed that the non-minimal coupling \( J(\eta) \) is given by eq. (2.13). In contrast, to evaluate the three-point function of interest, apart from \( J(\eta) \), we also need the behavior of \( \frac{dJ}{d\eta} \) [cf. eqs. (3.11)], which requires \( J(\phi) \). This can be arrived at easily. Let the auxiliary scalar field \( \phi \) that is evolving in de Sitter spacetime characterized by the scale factor (2.12) be described by the potential \( V(\phi) \). In de Sitter spacetime, the homogeneous scalar field \( \phi \) satisfies the following equation of motion:

\[
\phi'' - \frac{2}{\eta} \phi' + a^2 V_{,\phi} = 0,
\]

(3.12)

where \( V_{,\phi} = \frac{dV}{d\phi} \). If we now assume that \( V(\phi) = -3n M_{pl} H_0^2 \phi \), where \( n \) is a constant, then it is straightforward to show that, for a suitable choice of initial conditions, the solution to the above equation governing the scalar field can be written as [69]

\[
\phi(\eta) = -n M_{pl} \ln \eta.
\]

(3.13)

Therefore, upon setting \( J(\phi) = J_0 \exp(\phi/M_{pl}) \), we can arrive at the desired behavior of \( J(\eta) \) [as given by eq. (2.13)] that we had worked with. With \( J(\phi) \) at hand, we can, evidently, obtain \( \frac{dJ}{d\phi} \) to be

\[
\frac{dJ}{d\phi} = \frac{J(\phi)}{M_{pl}},
\]

(3.14)

thereby arriving at the required quantities related to the background.

We shall now evaluate the three-point function \( G_{\phi BB}(k_1, k_2, k_3) \) for two specific values of \( n \), as it proves to be difficult to evaluate the quantity for arbitrary \( n \). Therefore, we shall consider the two cases wherein \( n = 1 \) and \( n = 2 \). The \( n = 1 \) case leads to a blue-tilted power spectrum for the magnetic field with the spectral index \( n_B = 2 \). Whereas, the \( n = 2 \) case leads to the desired scale invariant spectrum. Note that the behavior of the mode \( f_k \) depends only on the scale factor [cf. eq. (3.8)]. As is well known, in de Sitter spacetime, the mode \( f_k \) satisfying the standard Bunch-Davies initial condition is given by

\[
f_k(\eta) = \frac{i H_0}{\sqrt{2k^3}} (1 + i k \eta) e^{-i k \eta}.
\]

(3.15)

3.1.1 The case of \( n = 1 \)

When \( n = 1 \), the electromagnetic mode \( \tilde{A}_k \) and its derivative \( \tilde{A}'_k \) can be written as

\[
\tilde{A}_k(\eta) = \sqrt{-\frac{\pi \eta}{4}} \left( \frac{\eta}{\eta_e} \right) e^{i\pi H_{3/2}^{(1)}(-k\eta)} = \frac{1}{\sqrt{2k^3 \eta_e}} (-i + k \eta) e^{-i k \eta},
\]

(3.16a)

\[
\tilde{A}'_k(\eta) = -k \sqrt{-\frac{\pi \eta}{4}} \left( \frac{\eta}{\eta_e} \right) e^{i\pi H_{3/2}^{(1)}(-k\eta)} = -i \sqrt{\frac{k}{2} \left( \frac{\eta}{\eta_e} \right)} e^{-i k \eta}.
\]

(3.16b)

Then, upon using the expressions (2.13) and (3.14) as well as the above modes in the integrals (3.11), we find that the integrals [viz. \( G_1(k_1, k_2, k_3) \) and \( G_2(k_1, k_2, k_3) \)] can be evaluated
easily (we have listed the results in the appendix). The two corresponding contributions to the three-point function can then be calculated to be

\[
G_{\delta\phi BB(1)}(k_1, k_2, k_3) = \frac{2 \pi H_0^4}{M_{\text{pl}}^2} \frac{(k_1 + k_T) (k_1^2 - k_2^2 - k_3^2)}{k_1^3 k_2 k_3 k_T^2},
\]

\[
G_{\delta\phi BB(2)}(k_1, k_2, k_3) = -\frac{\pi H_0^4}{2 M_{\text{pl}}^2} k_1^3 k_2^3 k_3^3 k_T^2 \left[ k_1^4 - 2 k_1^2 (k_2^2 + k_3^2) + k_1^2 + 6 k_1^2 k_2^2 + k_3^2 \right]
\times \left[ k_1^3 + k_2^3 + k_3^3 + 2 k_1^2 (k_2 + k_3) + 2 k_1 (k_2 + k_2 k_3 + k_3^3) + 2 k_2^3 + 2 k_2 k_3 + k_3^3 \right],
\]

where \( k_T = k_1 + k_2 + k_3 \). The complete three-point function \( G_{\delta\phi BB}(k_1, k_2, k_3) \) is evidently arrived at by adding the above two contributions.

### 3.1.2 The case of \( n = 2 \)

Let us now consider the case of \( n = 2 \). Since the scalar modes depend only on the scale factor, they remain the same as in the case of \( n = 1 \) [i.e. as given by eq. (3.15)]. Whereas, the electromagnetic mode and its derivative are given by

\[
\bar{A}_k(\eta) = -\frac{\pi}{4} \left( \frac{\eta}{\eta_e} \right)^2 e^{3i\pi/2} H_{1/2}^{(1)}(-k\eta) = \frac{-1}{\sqrt{2k^5 \eta_e^2}} (3 + 3i k \eta - k^2 \eta^2) e^{-i k \eta},
\]

\[
\bar{A}'_k(\eta) = -k \frac{\pi}{4} \left( \frac{\eta}{\eta_e} \right)^2 e^{3i\pi/2} H_{1/2}^{(1)}(-k\eta) = \frac{-\eta}{\sqrt{2k \eta_e^2}} (1 + i k \eta) e^{-i k \eta}.
\]

Upon evaluating the integrals (3.11) using the above modes (in this context, see appendix) and eventually taking the limit \( \eta_e \to 0 \), one can obtain that

\[
G_{\delta\phi BB(1)}(k_1, k_2, k_3) = \frac{18 \pi H_0^6 a^2(\eta_e)}{M_{\text{pl}}^2} \frac{(k_2^2 - k_3^2 - k_T^2)}{k_1^2 k_2^3 k_3^2 k_T^2} \left[ k_1^3 + 2 k_1^2 (k_2 + k_3) + 2 k_1^2 + 2 k_2 k_3 + 2 k_2 k_3^2 + k_3^3 \right],
\]

\[
G_{\delta\phi BB(2)}(k_1, k_2, k_3) = \frac{9 \pi H_0^6 a^2(\eta_e)}{2 M_{\text{pl}}^2} \frac{1}{k_1^3 k_2^3 k_3^3} \left[ k_1^4 - 2 k_1^2 (k_2^2 + k_3^2) + k_1^2 + 6 k_1^2 k_2^2 + k_3^2 \right]
\times \left\{ 3 \gamma_e + 3 \ln(-k_T \eta_e) - k_T^2 - \frac{k_3^2}{k_1^2} + 3 \left[ k_1^2 - k_1 (k_2 + k_3) - k_2 k_3 \right] k_T^2
\right.

\left. - k_2 k_3 \left[ 3 k_1^2 (k_2 + k_3) + k_1 (3 k_3^2 + 8 k_2 k_3 + 3 k_3^2) + k_2 k_3 (k_2 + k_3) \right] k_T^2 \right\},
\]

where \( \gamma_e \) is the Euler-Mascheroni constant. Clearly, the complete three-point function is a sum of the above two contributions.

A few clarifications need to made regarding the expressions we have arrived at above in the \( n = 2 \) case. To begin with, note that the two contributions in this case explicitly depend on \( \eta_e \) [cf. eqs. (3.19)]. The dependence arises through \( a^2(\eta_e) \) as an overall factor and the term \( \ln(-k_T \eta_e) \) that is encountered in the second contribution. While the first contribution
is relatively straightforward to arrive at, the second requires some care (when considering the \( \eta_e \to 0 \) limit), specifically, in order to arrive at the logarithmic term. Later, in section 4, we shall illustrate the amplitude and shape of the dimensionless non-Gaussianity parameter associated with the three-point function \( G_{\delta\phi BB}(k_1, k_2, k_3) \). The non-Gaussianity parameter will involve the ratio of the three-point function and the power spectra of the magnetic field as well as the perturbation in the scalar field. We shall see that the overall \( a^2(\eta_e) \) term will be cancelled by a similar term that arises in the power spectrum of the magnetic field. Also, we shall find that the logarithmic term considerably enhances the three-point function in the flattened limit (i.e. when \( k_1 = 2k_2 = 2k_3 \)) leading to a characteristic shape for the non-Gaussianity parameter [72].

### 3.2 The three-point function in the matter bounce

Let us now turn to the evaluation of the three-point function in the bouncing models. In this case, we shall assume the canonical scalar field \( \phi \) to be a free field. This choice is motivated by the fact that it will lead to a scale invariant spectrum for the perturbation in the scalar field in the matter bounce scenario (just as in de Sitter inflation) that we shall focus on [82, 84]. Such a scalar field is governed by the following equation of motion:

\[
\phi'' + 2 \mathcal{H} \phi' = 0. \tag{3.20}
\]

This equation can be immediately integrated to arrive at

\[
\phi' = \frac{C_\phi}{a^2}, \tag{3.21}
\]

where \( C_\phi \) is a constant of integration. Recall that, apart from the form of the coupling function \( J \), we require its derivative \( dJ/d\phi \) to calculate the three-point function. Upon using the quantity \( \phi' \) we have obtained above, \( dJ/d\phi \) can be expressed as

\[
\frac{dJ}{d\phi} = \frac{dJ}{d\eta} \frac{d\eta}{d\phi} = \frac{2 J_0 \bar{n} q k_0^2 a_0^{1/q}}{C_\phi} \eta^{\bar{n} + 2 - (1/q)}. \tag{3.22}
\]

In what follows, we shall assume the background to be the matter bounce scenario wherein \( q = 1 \), and we shall consider the cases \( \bar{n} = 1 \) and \( \bar{n} = 3/2 \). Since we are considering the perturbation \( \delta \phi \) to be a massless scalar field, it essentially behaves like the tensor perturbation. In the case of tensor perturbations, it is well known that the \( q = 1 \) case leads to scale invariant spectra [82]. It is for this reason that we shall focus on the case \( q = 1 \) in this work. Let us now understand the behavior of the modes. Since the Fourier modes \( f_k \) of the perturbation in the massless scalar field depend only on the scale factor [cf. eq. (3.8)], it can be solved for independent of the value of \( \bar{n} \). The modes \( f_k \) can be arrived at by dividing the period of interest into two domains (over \(-\infty < \eta < -\alpha \eta_0 \) and \(-\alpha \eta_0 < \eta < \beta \eta_0 \), where \( \alpha = 10^5 \) and \( \beta = 10^2 \)) just as we had done in the case of the electromagnetic modes. In the first domain, the mode is given by the following well known matter bounce form [82, 84]:

\[
f_k(\eta) = \frac{1}{\sqrt{2k}} \frac{1}{a_0 k_0^2 \eta^2} \left( 1 - \frac{i}{k \eta} \right) e^{-i k \eta}. \tag{3.23}
\]

While in the second domain, it can be obtained to be (in this context, see ref. [82])

\[
f_k(\eta) = S_{1k} + S_{2k} g_1(k_0 \eta), \tag{3.24}
\]
Figure 1. The behavior of the scalar mode $f_k$ (on the left) and the electromagnetic mode $\tilde{A}_k$ (on the right, for the case $\tilde{n} = 3/2$) in the matter bounce scenario (i.e. when $q = 1$) has been plotted as a function of time. We have chosen to work with a time variable called e-N-folds that is convenient to describe symmetric bounces [64]. Note that both the modes grow as one approaches the bounce. This property can lead to large non-Gaussianities. These plots correspond to a typical cosmological scale with wavenumber $k/k_0 = 10^{-20}$ and we should add that modes corresponding to all the scales of cosmological interest behave in a similar fashion. We should also point out that numerical analyses suggest that these analytical approximations match the exact numerical solutions very well [64, 65, 82].

where

$$S_{1k} = \frac{1}{\sqrt{2k}} \frac{1}{a_0 \alpha^2} \left(1 + \frac{i k_0}{\alpha k}\right) e^{i \alpha k/k_0} + S_{2k} g_1(\alpha),$$

$$S_{2k} = \frac{1}{\sqrt{2k}} \frac{1}{2a_0 \alpha^2} \left(1 + \alpha^2\right)^2 \left(3 \frac{i k_0}{\alpha^2 k} + \frac{3}{\alpha} - \frac{i k}{k_0}\right) e^{i \alpha k/k_0},$$

while the function $g_1(x)$ is given by

$$g_1(x) = \frac{x}{1 + x^2} + \tan^{-1} x.$$  

The behavior of the mode $f_k$ is plotted in figure 1 as a function of so-called e-N-folds $N$ in terms of which the scale factor is given by $a(N) = a_0 \exp(N^2/2)$ [64], where $a_0$ is the value of the scale factor at the bounce. Note that the modes $f_k$ and $\tilde{A}_k$ grow strongly as one approaches the bounce. Such a growth may lead to large non-Gaussianities in the bouncing scenarios.

3.2.1 The case of $\tilde{n} = 1$

Let us first consider the case of $\tilde{n} = 1$, as we had done in the context of inflation. In such a case, we have

$$\frac{dJ}{d\phi} = \frac{2 J_0 k_0^2 a_0^2}{C_\phi} \eta \left(1 + k_0^2 \eta^2\right)^2.$$  

Since we now know the background quantities as well as the behavior of the modes, we have all the information required to evaluate the integrals characterizing the three-point function [cf. eqs. (3.11)]. In order to calculate these integrals, evidently, we can divide the period of
interest (i.e. \(-\infty < \eta < \beta \eta_0\)) into two domains \((-\infty < \eta < -\alpha \eta_0\) and \(-\alpha \eta_0 < \eta < \beta \eta_0\)) over which we have constructed solutions for the modes.

In the first domain, for the bouncing scenario of our interest, the scale factor can be approximately written as \(a(\eta) \simeq a_0 k_0^2 \eta^2\). Therefore, we have [cf. eqs. (2.21) and (3.22)]

\[
J \frac{dJ}{d\phi} \simeq \frac{2 J_0^2 k_0^8 \alpha_0^4}{C_\phi} \eta^7 = J_{00} \eta^7, \tag{3.28}
\]

where we have set \(J_{00} = 2 J_0^2 k_0^8 \alpha_0^4 / C_\phi\). Also, when \(\bar{n} = 1\), the electromagnetic modes (2.22) and their time derivative reduce to

\[
\bar{A}_k(\eta) = \frac{-i}{\sqrt{2} k^3 a_0 J_0 k_0^2 \eta^3} (1 + i k \eta) e^{-ik \eta}, \tag{3.29a}
\]

\[
\bar{A}'_k(\eta) = \frac{1}{\sqrt{2} k^3 a_0 J_0 k_0^2 \eta^4} (3i - 3k \eta - ik^2 \eta^2) e^{-ik \eta}. \tag{3.29b}
\]

Now, in order to arrive at the three-point function, we need to evaluate the integrals (3.11). After writing these equations in terms of the coupling function and the scalar and electromagnetic modes, we find that the integrals involved are mainly of the following form:

\[
Q_m(k_T) = \int_{-\infty}^{-\alpha/k_0} d\eta \frac{e^{i k_T \eta}}{\eta^m}, \tag{3.30}
\]

which can be evaluated to be [85]

\[
Q_1(k_T) = i \pi + \operatorname{Ei} \left( -\frac{i k_T \alpha}{k_0} \right), \tag{3.31a}
\]

\[
Q_{m+1}(k_T) = \frac{i k_T}{m} Q_m(k_T) - \frac{e^{-i k_T \alpha/k_0}}{m} \left( \frac{-k_0}{\alpha} \right)^m, \tag{3.31b}
\]

with \(\operatorname{Ei}(z)\) being the exponential integral function. Therefore, in the first domain, the integrals (3.11) can be completely written in terms of the quantities \(Q_m(k_T)\) (see appendix for the complete expressions).

In the second domain, we have

\[
J \frac{dJ}{d\phi} = J_{01} \eta \left(1 + k_0^2 \eta^2\right)^3, \tag{3.32}
\]

where we have defined \(J_{01} = 2 J_0^2 k_0^2 \alpha_0^4 / C_\phi\). Also, the modes and their derivatives are given by the expressions [cf. eq. (2.26)]

\[
\tilde{A}_k(\eta) = B_{1k} + B_{2k} g_1(k_0 \eta), \tag{3.33a}
\]

\[
\tilde{A}'_k(\eta) = \frac{2 B_{2k} k_0}{(1 + k_0^2 \eta^2)^2}, \tag{3.33b}
\]

where

\[
B_{1k} = \tilde{A}_k(-\alpha \eta_0) + \frac{1}{2 k_0} \tilde{A}'_k(-\alpha \eta_0) \left(1 + \alpha^2\right)^2 g_1(\alpha), \tag{3.34a}
\]

\[
B_{2k} = \frac{1}{2 k_0} \tilde{A}'_k(-\alpha \eta_0) \left(1 + \alpha^2\right)^2, \tag{3.34b}
\]
with $\tilde{A}_k(-\alpha \eta_0)$ and $\tilde{A}_k'(-\alpha \eta_0)$ being obtained from the corresponding values evaluated at the end of the first domain [cf. eqs. (3.29)], while $g_1(x)$ is given by eq. (3.26). On using the above expressions, we find that the integrals (3.11) in the second domain are of the following form:

\[
G_1(k_1, k_2, k_3) = 4 i J_{01} B_{2k_2}^* B_{2k_3}^* \int_{-\alpha/k_0}^{\beta/k_0} \frac{d\eta}{1 + k_0^2 \eta^2} \left[ S_{k_1}^* + S_{k_2}^* g_1(k_0 \eta) \right], \quad (3.35a)
\]

\[
G_2(k_1, k_2, k_3) = i k_2 k_3 J_{01} \int_{-\alpha/k_0}^{\beta/k_0} d\eta \eta \left( 1 + k_0^2 \eta^2 \right)^3 \left[ S_{k_1}^* + S_{k_3}^* g_1(k_0 \eta) \right] \times \left[ B_{1k_2}^* + B_{2k_2}^* g_1(k_0 \eta) \right] \left[ B_{1k_3}^* + B_{2k_3}^* g_1(k_0 \eta) \right]. \quad (3.35b)
\]

These integrals can be evaluated easily in terms of elementary functions. Thereafter, these two integrals can be combined to arrive at the total contribution to the three-point function from the second domain.

### 3.2.2 The case of $\tilde{n} = 3/2$

For the case of $q = 1$ and $\tilde{n} = 3/2$, which is when scale invariant magnetic fields are generated, we have

\[
\frac{dJ}{d\phi} = \frac{3 J_0 k_0^2 a_0^{7/2}}{C_\phi} \eta \left( 1 + k_0^2 \eta^2 \right)^{5/2}. \quad (3.36)
\]

In the first domain, for the matter bounce scenario, we therefore have

\[
J \frac{dJ}{d\phi} = \frac{3 J_0^2 k_0^2 a_0^{5/2}}{C_\phi} \eta^9 = J_{10} \eta^9, \quad (3.37)
\]

where we have set $J_{10} = 3 J_0^2 k_0^2 a_0^5 / C_\phi$. In this case, the electromagnetic modes (2.22) in the first domain simplify to

\[
\tilde{A}_k(\eta) = \frac{1}{J_0 a_0^{3/2} k_0^{3/2}} \left( \frac{1}{\eta^3} - \frac{3 i}{k \eta^4} \right) e^{-i k \eta}, \quad (3.38a)
\]

\[
\tilde{A}_k'(\eta) = \frac{1}{J_0 a_0^{3/2} k_0^{3/2}} \left( \frac{15}{k^2 \eta^6} + \frac{15 i}{k \eta^7} - \frac{6 i}{\eta^5} \right) e^{-i k \eta}. \quad (3.38b)
\]

Using these solutions, we can compute the contribution to the three-point function from the first domain. We find that the integrals (3.11) can be completely expressed in terms of the functions $Q_m(k_\gamma)$ we had introduced in eqs. (3.30) and (3.31) (see appendix).

In the second domain, we have

\[
J \frac{dJ}{d\phi} = J_{11} \eta^4 \left( 1 + k_0^2 \eta^2 \right)^4, \quad (3.39)
\]

where we have defined $J_{11} = 3 J_0^2 k_0^2 a_0^5 / C_\phi$. Also, the electromagnetic modes are given by the following expressions [82]:

\[
\tilde{A}_k(\eta) = C_{1k} + C_{2k} g_{2/3}^1(k_0 \eta), \quad (3.40a)
\]

\[
\tilde{A}_k'(\eta) = \frac{8 C_{2k} k_0}{(1 + k_0^2 \eta^2)^3}, \quad (3.40b)
\]
where the quantities $C_{1k}$ and $C_{2k}$ can be written as

\begin{align}
C_{1k} &= \bar{A}_k(-\alpha \eta_0) + \frac{1}{8k_0} \bar{A}'_k(-\alpha \eta_0) \left(1 + \alpha^2\right)^3 g_2(\alpha), \\
C_{2k} &= \frac{1}{8k_0} \bar{A}'_k(-\alpha \eta_0) \left(1 + \alpha^2\right)^3,
\end{align}

while the function $g_2(x)$ is given by

\[g_2(x) = \frac{(5 + 3x^2)}{1 + x^2} + 3 \tan^{-1}(x).\]

Upon using the above expressions for the modes, we find that the integrals (3.11) in the second domain are of the following form:

\begin{align}
\mathcal{G}_1(k_1, k_2, k_3) &= 64i J_{11} C_{2k_1}^* C_{1k_2}^* k_0^2 \int_{-\alpha/k_0}^{\beta/k_0} \frac{d\eta \eta}{(1 + k_0^2 \eta^2)^2} \left[S_{1k_1}^* + S_{1k_1}^* g_1(k_0 \eta)\right], \\
\mathcal{G}_2(k_1, k_2, k_3) &= ik_2 k_3 J_{11} \int_{-\alpha/k_0}^{\beta/k_0} d\eta \eta \left(1 + k_0^2 \eta^2\right)^4 \left[S_{1k_1}^* + S_{1k_1}^* g_1(k_0 \eta)\right] \\
&\quad \times \left[C_{1k_2}^* + C_{2k_2}^* g_2(k_0 \eta)\right] \left[C_{1k_3}^* + C_{2k_3}^* g_2(k_0 \eta)\right].
\end{align}

These integrals can again be evaluated easily and expressed in terms of elementary functions and they can then be combined to arrive at the complete three-point function.

It is useful to note here that, on comparing the amplitude of the contributions to the three-point function from the first and second domains, we find that the second domain leads to a much larger contribution than that from the first domain in both the cases of $\bar{n} = 1$ and $\bar{n} = 3/2$. The final expressions describing the three-point functions prove to be quite lengthy and cumbersome. Due to this reason, rather than write them down explicitly, we shall instead illustrate the behavior of the corresponding non-Gaussianity parameter as density plots in the next section.

### 4 Amplitude and shape of the non-Gaussianity parameter

Motivated by definitions of the non-Gaussianity parameters describing the three-point auto and cross-correlations of the scalar and tensor perturbations [86, 87], we shall now define a non-Gaussianity parameter $b_{\text{NL}}$ to characterize the cross-correlation between the magnetic field and the perturbation in the scalar field. As we shall see, the parameter will prove to be a dimensionless quantity involving the ratio of the cross-correlation and the power spectra of the scalar perturbation and the magnetic field. The parameter captures the amplitude and shape of the three-point function, and we should clarify that it has a form very similar to the parameters defined earlier in this context [69, 71, 72]. In this section, we shall arrive at the expression for the non-Gaussianity parameter by following the same procedure as was used to arrive at similar parameters for the three-point functions involving the scalar and tensor perturbations [87]. With the definition at hand, we shall evaluate the parameter for the inflationary and bouncing scenarios of our interest.

The amplitude of the non-Gaussianity in the local model for the scalar three-point function is usually parameterized in terms of a parameter $f_{\text{NL}}$ which, in this model, coincides with
the bispectrum scaled by products of the power spectra. Here, we generalize that analogously to a non-Gaussianity parameter $b_{NL}$ which we define through the following relation:

$$
\mathcal{B}_{i,q}(\eta) = \mathcal{B}_{i,q}^{(G)}(\eta) + \frac{b_{NL}}{2 M_{Pl}} \int \frac{d^3p}{(2\pi)^{3/2}} \delta \phi_{q-p}(\eta) \mathcal{B}_{i,p}^{(G)}(\eta),
$$

(4.1)

where $\mathcal{B}_{i,q}$ is the Fourier mode of the actual magnetic field and $\mathcal{B}_{i,q}^{(G)}$ indicates the Fourier mode of its Gaussian part, while, as usual, $\delta \phi_{q-p}$ refers to Fourier mode of the perturbation in the scalar field which has already been assumed to be Gaussian. We can evaluate the three-point function and the power spectra $(\delta \phi_{k_1} \mathcal{B}_{k_2} \mathcal{B}_{k_3})$, upon using the above definition of $\mathcal{B}_{i,q}$ and Wick’s theorem which applies to Gaussian operators. On making use of the definition (3.9) of $G_{\delta \phi BB}(\mathbf{k}_1, \mathbf{k}_2, \mathbf{k}_3)$ and inverting the resulting expression, we obtain the following expression for $b_{NL}$:

$$
b_{NL}(\mathbf{k}_1, \mathbf{k}_2, \mathbf{k}_3) = \frac{1}{16 \pi^5} \frac{J^2(\eta_c)}{a^2(\eta_c)} \left[ k_1^3 k_2^3 k_3^3 G_{\delta \phi BB}(\mathbf{k}_1, \mathbf{k}_2, \mathbf{k}_3) \right]
$$

$$
\times \left\{ \mathcal{P}_{\delta \phi}(k_1) \left[ k_3^3 \mathcal{P}_\eta(k_2) + k_2^3 \mathcal{P}_\eta(k_3) \right] \right\}^{-1}.
$$

(4.2)

In this expression, $\mathcal{P}_\eta(k)$ is the power spectrum of the magnetic field we have discussed earlier, while $\mathcal{P}_{\delta \phi}(k)$ is the power spectrum of the scalar field, given by

$$
\mathcal{P}_{\delta \phi}(k) = \frac{k^3}{2 \pi^2 M_{Pl}^2} |H_k|^2,
$$

(4.3)

with the right hand side to be evaluated as $\eta_c \to 0$ in the context of inflation and at $\eta = \beta \eta_0$ in the context of the bouncing models. Due to their dual nature \[84\], both de Sitter inflation and matter bounce are expected to lead to scale invariant spectra for the perturbation in the scalar field. In de Sitter inflation, the spectrum is given by the well known scale invariant form

$$
\mathcal{P}_{\delta \phi}(k) = \frac{H_0^2}{4 \pi^2 M_{Pl}^2}.
$$

(4.4)

In the matter bounce, using the modes (3.24), it can be determined to be \[82\]

$$
\mathcal{P}_{\delta \phi}(k) = \frac{9 k_0^2}{16 a_0^2 M_{Pl}^2}.
$$

(4.5)

Let us first consider the amplitude and shape of the non-Gaussianity parameter $b_{NL}$ for an arbitrary triangular configuration of the wavevectors $\mathbf{k}_1, \mathbf{k}_2$ and $\mathbf{k}_3$ in the context of inflation. In de Sitter inflation, for the case of $n = 1$, from the two contributions (3.17) to the three-point function and the power spectra (2.18) and (4.4), the parameter $b_{NL}$ can be obtained to be

$$
b_{NL}(\mathbf{k}_1, \mathbf{k}_2, \mathbf{k}_3) = -\frac{1}{2 k_2^2 k_3^2 (k_2 + k_3) k_1^2} \left\{ 4 k_2^2 k_3^2 (k_1 + k_2) (-k_1^2 + k_2^2 + k_3^2)
$$

$$
+ k_1^2 - 2 k_2^2 (k_2 + k_3) + k_2^2 + 6 k_2^2 k_3^2 + k_3^2 \right\} \left[ k_1^2 + 2 k_2^2 (k_2 + k_3)
$$

$$
+ 2 k_1 (k_2^2 + k_2 k_3 + k_3^2) + k_3^2 + 2 k_2^2 k_3 + 2 k_2 k_3 + k_3^2 \right\}.
$$

(4.6)
Note that, in the squeezed limit, wherein \( k_1 \to 0 \) and \( k_2 = k_3 \), we have \( b_{nL} = -4 \). For the case of \( n = 2 \), the non-Gaussianity parameter can be obtained [from eqs. (3.19), (2.18) and (4.4)] to be

\[
b_{nL}(k_1, k_2, k_3) = \frac{1}{2 k_2^2 k_3^2 (k_3^2 + k_3^3) k_1^2} \left\{ 4 k_2^2 k_3^2 (k_1^2 - k_2^2 - k_3^3) \left[ k_1^3 + 2 k_1^2 (k_2 + k_3) + 2 k_1 (k_2^2 + k_2 k_3 + k_3^2) + k_2^2 + 2 k_2 k_3 + 2 k_2 k_3 + k_3^3 \right] - \left[ k_1^4 + k_2^2 + k_3^4 \right] - 2 k_1^2 \left( k_2^2 + k_3^2 \right) + 6 k_2^2 k_3^2 \right\} \left[ -3 \gamma_g k_1^3 k_2^3 - 3 k_1^3 k_2^2 \ln(-k_1 \eta_0) + k_2 k_3 \left( 3 k_1^2 (k_2 + k_3) + k_1 (3 k_2^3 + 8 k_2 k_3 + 3 k_3^3) + k_2 k_3 (2 k_3 + k_3) \right) \right] + 3 \left( k_1^4 - k_1 (k_2 + k_3) - k_2 k_3 \right) k_2^3 + k_1^5 \right\}. \tag{4.7}
\]

In the squeezed limit, we have \( b_{nL} = -8 \). In the next section, we shall discuss the properties of \( b_{nL} \) in the squeezed limit in more detail.

For the matter bounce scenario and the two cases of \( n = 1 \) and \( n = 3/2 \) that we had considered, we can arrive at the non-Gaussianity parameter \( b_{nL} \) from the various expressions we had obtained earlier and the corresponding power spectra. However, as the resulting expressions are too lengthy and cumbersome, we do not explicitly write them down here. We shall plot them below and compare them with the results in inflation.

In figures 2 and 3, we have illustrated the non-Gaussianity parameter \( b_{nL} \) as a density plot for an arbitrary triangular configuration of the wavevectors \( k_1, k_2, \) and \( k_3 \), as is often done for the scalar non-Gaussianity parameter \( f_{nL} \) (see, for instance, ref. [86]). In these plots, the x-axis corresponds to the ratio of the amplitudes of \( k_1 \) and \( k_2 \), while the y-axis
corresponds to the ratio of the amplitudes of $k_3$ and $k_2$. For the case of three-point functions involving perturbations of similar nature, such as the scalar and tensor bispectra, due to the symmetrical nature of these three-point functions, it is sufficient to construct these density plots over the domain $0.0 < k_1/k_2 < 1.0$ and $0.5 < k_3/k_2 < 1.0$. However, for the cases of three-point functions involving one mode of a nature dissimilar from the other two, such as in the case of the three-point function with one scalar mode and two electromagnetic modes that we are studying here, we find that the above ranges of ratios of the wavenumbers do not adequately represent all the various combinations of wavenumbers that can arise in such a context. Therefore, in figures 2 and 3, we have plotted the $b_{\text{NL}}$ parameter over the ranges $0.0 < k_1/k_2 < 2.0$ and $0.0 < k_3/k_2 < 1.0$. These values of the ratios of wavenumbers can satisfactorily represent the entire range of triangular configuration of wavevectors of our interest.

A few points need to be stressed regarding the results that have been illustrated in figures 2 and 3. Let us first discuss the case of de Sitter inflation. To begin with, note that, in this case, the amplitude as well as the shape of the non-Gaussianity parameter $b_{\text{NL}}$ is considerably different depending on whether $n = 1$ or $n = 2$. Also, the amplitude in the $n = 2$ case is considerably larger due to the appearance of the $\ln(-k_+ y_e)$ term, with the maximum values of the parameter arising in the flattened limit wherein $k_1 = 2 k_2 = 2 k_3$. Moreover, as we already mentioned, in the squeezed limit wherein $k_1 \to 0$ and $k_2 = k_3$, we have $b_{\text{NL}} = -4$ when $n = 1$ and $b_{\text{NL}} = -8$ when $n = 2$. This is essentially the so-called consistency relation which we shall establish in the next section for an arbitrary $n$ in the case of inflation. In contrast, the non-Gaussianity parameter seems to have primarily the same shape for $n = 1$ and $n = 3/2$ in the matter bounce case. This can be attributed to the fact that, as the wavenumbers of cosmological interest are much smaller than the bounce scale, the matter bounce scenario is unable to strongly discriminate between these

---

**Figure 3.** The dimensionless non-Gaussianity parameter $b_{\text{NL}}$ arising in the matter bounce scenario has been illustrated in the form of density plots as in the previous figure for the two cases of $\bar{n}$ we had discussed ($\bar{n} = 1$ on the left and $\bar{n} = 3/2$ on the right). When compared with the results in the inflationary case, two points are evident. Firstly, the shape of the parameter proves to be considerably more homogeneous. This is primarily because of the fact that all the scales of cosmological interest are much smaller than the bounce scale $k_0$, and hence the simple bouncing scenario we are considering here does not strongly discriminate between the wavenumbers of interest. Secondly, the amplitude of $b_{\text{NL}}$ is considerably larger. This can be completely attributed to the forms of the coupling functions that we have considered. Moreover, in the $\bar{n} = 3/2$ case, there arises a strong red tilt with, say, $b_{\text{NL}}$ behaving as $k^{-2}$ in the equilateral limit, which leads to even larger values (compared to the $\bar{n} = 1$ case, where it is nearly scale invariant) over cosmological scales. In contrast, in de Sitter inflation, $b_{\text{NL}}$ is nearly scale invariant in all the limits for both the values of $n$ that we have considered.
modes. However, the amplitude of $b_{NL}$ in the matter bounce is considerably larger than in de Sitter inflation, which is possibly because of the form of the coupling function that we have considered. While, for $\bar{n} = 1$, $b_{NL}$ is nearly scale invariant, say, in the equilateral limit, we find that the parameter has a strong red tilt when $\bar{n} = 3/2$ (with $b_{NL}$ behaving as $k^{-2}$), leading to rather large values for the small wavenumbers (say, for $10^{-20} < k/k_0 < 10^{-15}$) corresponding to cosmological scales. We shall discuss the implications of this result in the concluding section.

5 The three-point function in the squeezed limit and the consistency relation

One of the most important characteristics of three-point functions is their behavior in the squeezed limit of the three wavenumbers, viz. when one of the three wavenumbers is much smaller than the other two, or, equivalently, when one of the three wavelengths is much longer than the other two. For the case of inflation, in this limit, the longest wavelength mode freezes on super Hubble scales and therefore acts as a background for the smaller wavelength modes. Consequently, the three-point function can be expressed in terms of the two-point functions involving the perturbations through the so-called consistency relation [75, 76]. In this section, we shall obtain the consistency relation for the three-point function involving the magnetic field and the scalar perturbation in the case of de Sitter inflation. We shall also discuss its validity in the bouncing scenario.

Let us first consider the case of de Sitter inflation. In the squeezed limit, i.e. when $k_1 \rightarrow 0$ and, say, $k_2 = -k_3 = k$, the scalar mode with wavenumber $k_1$ can be considered to have exited the Hubble radius and hence its amplitude can be treated as a constant. Therefore, the mode $f_k$ can be extracted out of the integrals (3.11). For the coupling function $J(\phi)$ that we had considered, given the modes (2.16), we obtain that, for arbitrary $n$ [85],

$$G_1(k_1, k, -k) = \frac{i}{M_{Pl}} \int_{-\infty}^{\eta_0} d\eta J^2(\eta) f^*_k(\eta) \bar{A}_{k}^{\ast 2}(\eta)$$

$$\approx \frac{i}{M_{Pl}} f^*_k(\eta_0) \int_{-\infty}^{\eta_0} d\eta J^2(\eta) \bar{A}_{k}^{\ast 2}(\eta)$$

$$= \frac{i \pi k^2 \eta_0^2 e^{-i n \pi}}{8 M_{Pl}} f^*_k(\eta_0)$$

$$\times \left\{ \left[ H_{n-1/2}^{(2)}(-k \eta_0) \right]^2 - H_{n-3/2}^{(2)}(-k \eta_0) H_{n+1/2}^{(2)}(-k \eta_0) \right\}, \quad (5.1a)$$

$$G_2(k_1, k, -k) = \frac{i}{M_{Pl}} k^2 \int_{-\infty}^{\eta_0} d\eta J^2(\eta) f^*_k(\eta) \bar{A}_{k}^{\ast 2}(\eta)$$

$$\approx \frac{i k^2}{M_{Pl}} f^*_k(\eta_0) \int_{-\infty}^{\eta_0} d\eta J^2(\eta) \bar{A}_{k}^{\ast 2}(\eta)$$

$$= \frac{i \pi k^2 \eta_0^2 e^{-i n \pi}}{8 M_{Pl}} f^*_k(\eta_0)$$

$$\times \left\{ \left[ H_{n+1/2}^{(2)}(-k \eta_0) \right]^2 - H_{n-1/2}^{(2)}(-k \eta_0) H_{n+3/2}^{(2)}(-k \eta_0) \right\}. \quad (5.1b)$$

Adding the contributions due to these two integrals, the three-point function in the squeezed
limit can be written as
\[
G_{\delta \phi BB}(k_1, k, -k) = -\frac{i \pi^3 H_0^2 \eta_e^5 k^4}{2 M_P^2} \left| f_{k_1}^e(\eta_e) \right|^2 \times \left\{ \left[ H^{(1)}_{n+1/2}(-k \eta_e) \right]^2 + \left[ H^{(2)}_{n-1/2}(-k \eta_e) \right]^2 + \left[ H^{(2)}_{n+1/2}(-k \eta_e) \right]^2 \right\} - \left[ H^{(2)}_{n+1/2}(-k \eta_e) \right]^2 \left\{ \left[ H^{(1)}_{n-1/2}(-k \eta_e) \right]^2 + \left[ H^{(1)}_{n+1/2}(-k \eta_e) \right]^2 - \left[ H^{(1)}_{n-3/2}(-k \eta_e) \right]^2 \times \left[ H^{(1)}_{n-1/2}(-k \eta_e) \right]^2 \times \left[ H^{(1)}_{n+1/2}(-k \eta_e) \right]^2 \times \left[ H^{(1)}_{n+3/2}(-k \eta_e) \right]^2 \right\}.
\]

Using this result, the expressions for the power spectra of the scalar field and the magnetic field as well as the behavior of Hankel functions \(H_n(x)\) for small values of \(x\), we can obtain the non-Gaussianity parameter in the squeezed limit to be [85]
\[
\lim_{k_1 \to 0} b_{nL}(k_1, k, -k) = 2n - 8,
\]
where \(n = (4 - 2n)\) is the spectral index of the power spectrum of the magnetic field. This implies that, in the squeezed limit, \(b_{nL} = -4\) for \(n = 1\) and \(b_{nL} = -8\) for \(n = 2\), results that we had already arrived at in the previous section.

In the bouncing scenario under consideration, we find that the scalar mode strongly grows as one approaches the bounce and, in fact, also exhibits a slow growth even after the bounce (in this context, see figure 1). Specifically, in contrast to its behavior in de Sitter inflation, the scalar mode \(f_k\) does not become a constant at late times. Therefore, it can be expected that, contrary to the reduced integrals (5.1) that we had obtained in the squeezed limit in the inflationary context, the corresponding integrals in bounces would involve all the three modes. Consequently, the consistency relation (5.3) that is valid in the case of de Sitter inflation may not hold true in the bouncing model. On evaluating the three-point function and the non-Gaussianity parameter in the bouncing model in the bounce, we find that the consistency relation is indeed violated. The violation of the consistency relation corresponding to the tensor bispectrum in a matter bounce was observed in a previous work [82], and it is interesting to note that a similar behavior is exhibited by the three-point function involving one scalar and two electromagnetic modes as well. This difference in the behavior of the non-Gaussianity parameter between de Sitter inflation and matter bounce scenarios, despite the similarities in the two-point functions obtained in these two models, can potentially serve as a discriminator between the inflationary paradigm and the bouncing scenarios.

6 Discussion

The magnetic fields existing on various scales in the universe are considered to have originated from a primordial seed field. Although the generation of such fields via the inflationary mechanism has been well studied, there have been far fewer endeavors to investigate the origin of the primordial magnetic fields in bouncing models. One of the most important signatures of such fields would be the extent of non-Gaussianity associated with the cross-correlations
between these fields and the scalar perturbations. These three-point functions have been evaluated in certain inflationary scenarios and it has been found that the corresponding non-Gaussianity parameter can be expected to be quite large.

In the matter bounce scenario of our interest, the modes grow as one approaches the bounce, and grow very slowly thereafter. Due to the enhancement in the amplitude of the modes, it can be expected that the non-Gaussianities associated with the three-point functions would be very large. In a previous work [82], it was shown that irrespective of the growth of the tensor modes in a matter bounce, the corresponding tensor non-Gaussianities are rather small and the consistency relation for the tensor bispectrum is violated. In contrast, in this work, we find that the non-Gaussianity parameter associated with the cross-correlations involving the primordial magnetic fields and the scalar perturbations is very large and, in fact, is much larger than what is expected in the de Sitter inflationary scenario. Further, the corresponding consistency relation is violated in the bouncing model. It should be noted that the bouncing scenario that we have considered here suffers from considerable backreaction in the vicinity of the bounce [64, 65], which can possibly be responsible for the large non-Gaussianities that we encounter. This issue of circumventing the backreaction in the proximity of the bounce is non-trivial and needs to be investigated in more detail.

Recall that we have restricted ourselves to the matter bounce scenario. Evidently, other combinations of the parameters $\bar{n}$ and $q$ can also lead to scale invariant magnetic power spectra of relevant amplitude. It would be interesting to examine whether other scenarios that result in similar amplitude for the scale invariant power spectrum also lead to similar results for the non-Gaussianities. Note that the extent of non-Gaussianities depends on $J(\phi)$ as well as $dJ/d\phi$, with the latter depending on $\phi'$ [cf. eq. (3.22)]. Therefore, it is important to explore a wide variety of coupling functions $J(\phi)$, some of which may lead to considerably different levels of non-Gaussianities. It seems difficult to be able to make generic remarks regarding the results one can obtain from different forms of couplings. Therefore, one may have to examine the effects of each type of coupling separately. We believe that it may be challenging to simultaneously produce magnetic fields of observable strengths in bounces while also ensuring that the levels of non-Gaussianities remain as small as encountered in inflation. We are currently systematically exploring these issues.

Acknowledgments

This work was initiated during visits by DC and LS to the Department of Physics and Astronomy, Johns Hopkins University, Baltimore, Maryland, U.S.A. under the aegis of The Indo-US Science and Technology Forum grant IUSSTF/JC-Fundamental Tests of Cosmology/2-2014/2015-16. DC would like to thank the Indian Institute of Technology Madras, Chennai, India, for financial support through half-time research assistantship. A Evaluation of integrals

In this appendix, we shall provide the results for the integrals $G_1(k_1, k_2, k_3)$ and $G_2(k_1, k_2, k_3)$ [cf. eqs. (3.11)] evaluated in de Sitter inflation and in the first domain in the matter bounce scenario of our interest.
Let us first consider the $n = 1$ case in de Sitter inflation. In this case, we find that the integrals can be evaluated to be

$$
G_1(k_1, k_2, k_3) = \frac{i H_0 \sqrt{2} k_3 e^{i k_T \eta_e}}{\sqrt{8} k_1^3 k_2^2 k_3 M_{pl}^2} \left( -i k_1 k_T \eta_e + 2 k_1 + k_2 + k_3 \right), \quad (A.1a)
$$

$$
G_2(k_1, k_2, k_3) = \frac{H_0 k_2 k_3 e^{i k_T \eta_e}}{\sqrt{8} k_1^3 k_2^2 k_3 M_{pl}^2} \left\{ \frac{1}{\eta_e} - \frac{k_1 k_2 k_3 \eta_e}{k_T} - i \frac{k_2}{k_T} \left[ k_3^2 (k_2 + k_3) + k_1 \left( k_2^2 + 4 k_2 k_3 + k_3^2 \right) + k_2 k_3 (k_2 + k_3) \right] \right\}. \quad (A.1b)
$$

In the case of $n = 2$, we find that the integrals are given by

$$
G_1(k_1, k_2, k_3) = \frac{i H_0 \sqrt{2} k_3 e^{i k_T \eta_e}}{\sqrt{8} k_1^3 k_2^2 k_3 M_{pl}^2} \left[ \frac{i}{\eta_e} - \frac{i k_1 k_2 k_3 \eta_e}{k_T} + \frac{k_1^2 (k_2 + k_3) + k_1 \left( k_2^2 + 4 k_2 k_3 + k_3^2 \right) + k_2 k_3 (k_2 + k_3)}{k_T^2} \right], \quad (A.2a)
$$

$$
G_2(k_1, k_2, k_3) = \frac{H_0 k_2 k_3}{\sqrt{8} k_1^3 k_2^2 k_3 M_{pl}^2} \left\{ 3 i k_2^3 \left[ \text{Ei} (i k_T \eta_e) + i \pi \right] + e^{i k_T \eta_e} \left[ -3 \frac{3}{\eta_e^2} \right. \right. \\
\left. \left. \left. - i k_2 k_3 \left[ 3 k_3^2 (k_2 + k_3) + k_1 \left( 3 k_2^2 + 8 k_2 k_3 + 3 k_3^2 \right) + k_2 k_3 (k_2 + k_3) \right] \right. \right. \\
\left. \right. \left. + 3 \left[ -k_1^2 + k_1 (k_2 + k_3) + k_2 k_3 \right] \frac{k_2}{\eta_e} - \frac{k_1 k_2 k_3 \eta_e}{k_T} + \frac{3 i k_T}{\eta_e^2} \right\}. \quad (A.2b)
$$

It should be mentioned that the integrals have been regulated (as is usually done in this context) in the $\eta \to -\infty$ limit to arrive at the above results.

Let us now turn to the case of the bouncing scenario. In the first domain, as in the inflationary case, the integrals have to be suitably regulated in the first domain (in the $\eta \to -\infty$ limit) to arrive at the required results. The integrals in the second domain do not entail considering any non-trivial limits and can be evaluated in a straightforward manner. Moreover, the results for the integrals in the second domain prove to be rather lengthy. Therefore, in what follows, we shall provide the results only in the first domain.

In the $\bar{n} = 1$ case, we find that the integrals are given by

$$
G_1(k_1, k_2, k_3) = \frac{a_0}{\sqrt{2} \alpha^3 C_\phi (k_1 k_2 k_3)\sqrt{2} k_3^2 k_2^2} \left\{ 3 i \alpha^3 k_0 k_3^3 k_2 e^{i \alpha k_T / k_0} \text{Ei} \left( -\frac{i k_T}{k_0} \right) \right. \\
\left. + 3 k_0^3 k_T^2 + 3 i \alpha k_0^3 k_T^3 + 3 \alpha^2 k_0^3 k_T^2 \left[ k_1^2 - k_1 (k_2 + k_3) - k_2 k_3 \right] \right. \\
\left. - \alpha^3 k_0 \left[ 3 \pi k_1^5 e^{i \alpha k_T / k_0} + 6 \pi k_1^4 (k_2 + k_3) e^{i \alpha k_T / k_0} + i k_2^2 k_3^2 (k_2 + k_3) \right. \right. \\
\left. \left. + 3 \pi k_1^4 (k_2 + k_3) k_T k_2 k_3 (k_2 + k_3) + i k_1 k_2 k_3 \left( 3 k_3^2 + 8 k_2 k_3 + 3 k_3^2 \right) \right] + \alpha^4 k_1 k_2^2 k_3^2 k_T \right\}, \quad (A.3a)
$$

$$
G_2(k_1, k_2, k_3) = \frac{a_0}{\sqrt{2} \alpha C_\phi (k_1 k_2 k_3)\sqrt{2} k_3^2 k_2^2} \left\{ k_0^2 k_T^2 + i \alpha k_0 \left[ k_0^2 (k_2 + k_3) \right. \right. \\
\left. \left. + k_1 \left( k_2^2 + 4 k_2 k_3 + k_3^2 \right) + k_2 k_3 (k_2 + k_3) \right] - \alpha^2 k_1 k_2 k_3 k_T \right\}. \quad (A.3b)
$$
While, in the $\tilde{n} = 3/2$ case, they can be obtained to be

$$\mathcal{G}_1(k_1, k_2, k_3) = -\frac{3 a_0 k_0 e^{-i \alpha k_T/k_0}}{4 \sqrt{2} \alpha^3 C_g k_1^{3/2} k_2^{5/2} k_3^{5/2} k_T} \left\{ 90 k_0^5 k_T^2 + 90 i \alpha k_0^5 k_T^3 \\
- 15 i \alpha^5 k_0 k_1^2 k_T^2 (k_1^2 - k_2^2 - k_3^2) e^{i \alpha k_T/k_0} Ei\left(-i \frac{k_T \alpha}{k_0}\right) \\
+ 30 \alpha^2 k_0^4 k_T^2 \left[ k_1^2 - 3 k_1 (k_2 + k_3) - k_2^2 - 3 k_2 k_3 - k_3^2 \right] - 15 i \alpha^3 k_0^3 k_T^2 k_T^3 \\
- 2 k_T^2 (k_2 + k_3) + 2 k_1 \left( k_2^2 + 3 k_2 k_3 + k_3^2 \right) + 2 k_2 (k_2 + k_3) \right\},$$

(A.4a)

$$\mathcal{G}_2(k_1, k_2, k_3) = -\frac{3 a_0 k_0 k_2 k_3 e^{-i \alpha k_T/k_0}}{2 \sqrt{2} \alpha^3 C_g k_1^{3/2} k_2^{5/2} k_3^{5/2} k_T} \left\{ 3 i \alpha^3 k_0 k_1^3 k_T^2 e^{i \alpha k_T/k_0} Ei\left(-i \frac{k_T \alpha}{k_0}\right) \\
+ 3 k_0^4 k_T^2 + 3 i \alpha k_0^3 k_T^3 + 3 \alpha^2 k_0^2 k_T^2 \left[ k_1^2 - k_1 (k_2 + k_3) - k_2 k_3 \right] \\
- \alpha^3 k_0 \left[ 3 \pi k_0^3 e^{i \alpha k_T/k_0} + 6 \pi k_1^4 (k_2 + k_3) e^{i \alpha k_T/k_0} \\
+ 3 \pi k_1^3 (k_2 + k_3)^2 e^{i \alpha k_T/k_0} + 3 i k_1^2 k_2 k_3 (k_2 + k_3) \\
+ i k_1 k_2 k_3 \left( 3 k_2^2 - 8 k_2 k_3 + 3 k_3^2 \right) + 3 i k_2^2 k_3^2 (k_2 + k_3) \right] + 4 \alpha^4 k_1 k_2^4 k_3^4 k_T \right\},$$
