Kleinian groups with ubiquitous surface subgroups

Joseph D. Masters

February 1, 2008

Abstract

We show that every finitely-generated free subgroup of a right-angled, co-compact Kleinian reflection group is contained in a surface subgroup.

1 Introduction

It is conjectured that every co-compact Kleinian group contains a surface subgroup. We show that, for some special examples, much more is true.

Theorem 1.1. Let $P$ be a right-angled, compact Coxeter polyhedron in $\mathbb{H}^3$, and let $\Gamma(P) \subset \text{Isom}(\mathbb{H}^3)$ be the group generated by reflections in the faces of $P$. Then every finitely-generated free subgroup of $\Gamma(P)$ is contained in a surface subgroup of $\Gamma(P)$.

Remarks:
1. It is well-known that every such $\Gamma(P)$ contains a surface subgroup. Indeed, it was shown in [5] that the number of “inequivalent” surface subgroups of $\Gamma(P)$ grows factorially with the genus.
2. Lewis Bowen has recently applied Theorem 1.1 to show that every such $\Gamma(P)$ contains a sequence of surface subgroups for which the Hausdorff dimensions of the limit sets approach two (see [2]).

2 Outline of the proof

Given a free subgroup $F$, we look at the convex core $\text{Core}(F) = \text{Hull}(\Lambda(F))/F$, which will be homeomorphic to a handlebody. Replacing $\text{Hull}(\Lambda(F))$ with a suitable neighborhood in $\mathbb{H}^3$, we can expand the handlebody to make it polyhedral, so that the boundary is a union of copies of the faces of $F$. By expanding further, we can make the induced decomposition of the boundary finer and finer. If we expand enough, it becomes possible to attach mirrors to certain faces along the boundary (see Figure 1), in such a way that the resulting 3-orbifold is the product of a compact 2-orbifold with an interval. The desired surface group is a finite-index subgroup of the 2-orbifold group.

3 Proof

Proof. The first ingredient is the Tameness Theorem. Let $F$ be a free subgroup of $\Gamma(P)$. Then by [1] and [4], the (infinite-volume) hyperbolic manifold $\mathbb{H}^3/F$ is topologically tame,
i.e. homeomorphic to the interior of a compact 3-manifold. Then work of Canary ([3])
implies that $F$ is geometrically finite—i.e. if $C$ is the convex hull of the limit set of $F$, then
$C/F$ is compact.

The next step, based on the ideas of [6], is to give a polyhedral structure to $C/F$. Let $T$
be the tesselation of $H^3$ by copies of $P$, and let $C^+$ be the tiling hull of $F$– this is the
union of all the tiles in $T$ which meet $C$. Then $C^+$ is invariant under $F$, and $C^+/F$ is a
compact, irreducible 3-manifold with free fundamental group. Thus $C^+/F$ is a handlebody
$W$.

The tesselation $T$ induces a tesselation of $\partial W$. Since all dihedral angles of $P$ are $\pi/2$,
then every pair of adjacent faces in $\partial W$ will meet at an angle of either $\pi/2$ or $\pi$. However,
if two faces meet at an angle of $\pi$, then we actually consider them as part of a single face.
Thus, every face in $\partial W$ can be decomposed as a union $F = X_1 \cup \ldots \cup X_m$, where each
$X_i$ is congruent to a face of the original polyhedron $P$. Along each $X_i$, we may attach
to $W$ a copy of $P$, to obtain a handlebody with convex boundary containing $W$, called
the expansion of $W$ along $F$. More generally, we define an expansion of $W$ to be a
handlebody $W'$ ⊃ $W$, obtained from $W$ by a finite sequence of such operations.

Let $g$ be the genus of $H$, and represent $H$ as $P \times I$, for a planar surface $P$. Let $\alpha_1, \ldots, \alpha_{g+1}$
be the boundary curves of $P \times \{0\}$. Say that a collection of faces $F$ of $\partial H$ forms a face
annulus if the faces can be indexed as $F_1, \ldots, F_n$, where $F_i$ is adjacent to $F_j$ if and only if
$|i - j| = 1$ (mod n), and $\cap_i F_i = \emptyset$. The last condition excludes the case of three faces
meeting at a vertex.

The following lemma is the key to proving Theorem 1.1.

**Lemma 3.1.** There is an expansion $W'$ of $W$, and a collection $F$ of disjoint face annuli
$A_1, \ldots, A_n \subset \partial W'$, so that the core curve of $A_i$ is freely homotopic to $\alpha_i$ in $W'$.

**Proof.** Let $A = \cup_i \alpha_i$. Our first claim is that there is an expansion $W'$ of $W$ so that, after
an isotopy of the $\alpha_i$’s to $\partial W'$, we have $F \cap A$ being connected for each $F \in \partial W'$.

We may assume, after an isotopy, that each face in $\partial W$ meets $A$ in a collection of
disjoint, properly embedded arcs. Let

$$k = k(A) = \text{Max}_{F \in \partial W} |F \cap A|.$$ 

Suppose $k > 1$. Let $n(A)$ be the number of faces in $\partial W$ which meet $A$ in $k$ components.
Let $F \in \partial W$ such that $|F \cap A| = k$, and let $W'$ be the expansion of $W$ along $F$. Note
that $W' - W$ is a polyhedron $P'$ (made up of copies of $P$) with dihedral angles $\pi/2$. Let
$F'$ be the face of $P'$ which is identified to $F$, and let $F_1', \ldots, F_n'$ be the faces in $P'$ which are
adjacent to $F'$, in cyclic order.
Let $N_1(F') = \bigcup F'_i \cup \ldots \cup F'_n$, and let $N_2(F')$ be the union of $N_1(F')$ together with all faces in $P'$ which meet faces in $N_1(F')$. Since $P'$ is a Coxeter polyhedron in $\mathbb{H}^3$, it follows that $\text{int} N_2(F')$ is an embedded disk.

Recall that $\mathcal{A} \cap F$ consists of $k$ disjoint arcs; let $\beta_1, \ldots, \beta_k$ be the images of these arcs in $F'$, and let $(p_i, q_i)$ be the endpoints of $\beta_i$.

**Lemma 3.2.** There are disjoint arcs $\gamma_i$ in $\partial P' - F'$, with endpoints $(p_i, q_i)$, so that:
1. $|F^* \cap (\cup \gamma_i)| < k$, for all faces $F^*$ in $\partial P' - N_1(F')$.
2. $|F'_j \cap (\cup \gamma_i)| = |F'_j \cap (\cup \partial \beta_i)|$ for all $j$.

**Proof.** (Of Lemma 3.2)

**Case 1:** There are four endpoints (say $(p_1, q_1), (p_2, q_2)$) which lie on four distinct sides of $F'$.

In this case, we let $\delta$ be a properly embedded arc in $N_1(F')$, disjoint from $\cup_i \beta_i$, which separates $\beta_1$ and $\beta_2$ (See Figure 2). For each $i$, let $\beta_i^+$ (resp. $\beta_i^-$) be an arc, properly embedded in some $F_j$, so that one endpoint is on $\partial N_1(F)$, the other is the point $p_i$ (resp. $q_i$), and so that the arcs $\beta_1^+, \beta_2^+, \ldots$ are all disjoint from each other and from $\delta$. Let $\beta_i^*$ be the component of $\partial N_1(F') - (\beta_i^+ \cup \beta_i^-)$ which is disjoint from $\delta$. Let $\gamma_i = \beta_i^+ \cup \beta_i^- \cup \beta_i^*$. After an isotopy (supported in a neighborhood of $\beta_i^*$ in $N_2(F') - \text{int} N_1(F')$) the arcs $\gamma_i$ satisfy the hypotheses of the lemma.

**Case 2:** Suppose that some edge of $F$ meets every arc $\beta_i$.

We repeat the construction from Case 1. (i.e. pick an arc $\delta$ in $N_1(F')$ disjoint from the $\beta_i$’s, separating $\beta_1$ and $\beta_2$; then construct $\beta_i^+\delta$, $\beta_i^*\delta$, and $\gamma_i\delta$.) The only difference is that we must arrange that the arcs $\beta_1^+, \beta_2^+, \ldots$ are not all parallel (i.e. their union meets at least
three distinct sides), and that the arcs $\beta_1, \beta_2, \ldots$ are not all parallel. This can be done, since, $P'$ being a right-angled Coxeter polyhedron in $\mathbb{H}^3$, each $F'_i$ has at least five edges. (See Figure 3).

![Figure 3: Construction of $\gamma_i$'s (Case 2).](image)

Now we return to the proof of Lemma 3.1. We obtain a loop $\alpha'_i$ in $W'$, by replacing each $\beta_j \subset \alpha_i$ with $\gamma_j$. Let $A' = \cup \alpha'_i$. Since the face $F$ has been removed, and replaced by faces which meet $A'$ in fewer than $k$ components, we have $n(A') < n(A)$.

Similarly, we see that, by enlarging $W$ repeatedly, $n(A)$ can be reduced until it reaches 0. By further enlargements, we may assume that $k(A) = 1$. So we may assume that $F \cap A$ is connected for each $F$.

Let $A_i$ be the union of the faces which meet $\alpha_i$. For each face $F$ in $\cup A_i$, let us define the overlap of $F$ by the formula:

$$o(F) = (\text{Number of faces in } \cup A_i \text{ which are adjacent to } F) - 2.$$ 

Since the core curve of $A_i$ is essential in $W$, no point in $\partial W$ meets every face in $A_i$. Thus, if $o(F) = 0$ for all $F \in \cup A_i$, then the $A_i$’s are the disjoint face annuli we are looking for.

Let $F$ be a face in $A_i$, let $F_1$ and $F_2$ be the two faces in $A_i$ which are consecutive to $F$, and let $e_i = F \cap F_i$. Let $\gamma_1$ and $\gamma_2$ be the components of $\partial F - \{e_1 \cup e_2\}$. We say that $F$ is good if one of the $\gamma_i$’s is disjoint from the interior of $\cup A_i$.

Case 3: Every face in $\cup A_i$ is good.

Let $F$ be a face in some $A_i$, and let $\beta = F \cap (\cup \alpha_i)$. By previous assumption, $\beta$ is connected. Let $p$ and $q$ be the endpoints of $\beta$. As before, let $W'$ be the enlargement of $W$ along $F$, let $P' = W' - \text{int } W$, and let $F'$ be the face of $W'$ which is identified to $F$. Let $F'_1, \ldots, F'_n$ be the faces adjacent to $F'$ in $P'$, labeled consecutively, so that $p \in \partial F'_1$ and
$q \in \partial F_i'$. Since $F$ is good, then we may assume that none of the faces $F_1', ..., F_i'$ is glued to a face in $\cup A_i$.

As in the proof of Lemma 3.2, we replace $\beta$ with an appropriate arc $\gamma \subset \partial P' - F'$. In this case, we choose arcs $\beta^+$ (resp. $\beta^-$) from $p$ (resp. $q$) to $\partial N_1(F')$, so that $\beta^+$ and $\beta^-$ each meet only one face of $\partial P'$. We let $\beta^*$ be the component of $\partial N_1(F') - (\beta^+_1 \cup \beta^-_1)$ contained in $F_1', ..., F_i'$; then we perturb $\beta^*$ so that it is a properly embedded arc in $N_2(F') - N_1(F')$. See Figure 4.

Figure 4: Construction of $\gamma$ in Case 3. Only shaded faces can be glued to $\cup A_i$.

A complication is that $\partial N_2(F')$ may not be an embedded circle in $P'$, and thus there may be pairs of adjacent faces in $P'$ which meet $\beta^*$ non-consecutively. In this case, we perform “shortcut” operations on $\beta^*$, as indicated in Figure 5.

Let $\gamma = \beta^+ \cup \beta^- \cup \beta^*$. Then we have the required arc $\gamma$, and a new loop $\alpha'$. The number of faces with positive overlap decreases, so eventually we may eliminate them all.

**Case 4:** Suppose there is a face $F$ in $\cup A_i$ which is not good.

Here the construction is similar to the construction of Case 3. In this case, we choose $\beta^*$ to be either of the two components of $\partial N_1(F') - (\beta^+_1 \cup \beta^-_1)$; then we push $\beta^*$ off of $\partial N_1(F')$; and then, as in Case 3, we perform shortcuts if possible. The result is that the face $F$ is removed, and replaced with good faces. Repeating this operation along all faces which are not good, we may reduce to Case 3.

Thus, we have shown that, after a sequence of enlargements, every face in $\cup A_i$ has zero overlap. Thus we have constructed the required $A_i$’s, completing the proof of Lemma 3.1.

Returning to the proof of Theorem 1.1 we let $G$ be the group generated by $F$, together with the reflections in the lifts to $\mathbb{H}^3$ of the faces of the face annuli $A_1, ..., A_n$. Then we claim that $G$ is the group of a closed, hyperbolic 2-orbifold.
Figure 5: If the edges with arrows are actually the same, then it is possible to shorten the arc $\beta^\ast$.

Indeed, let $V$ be the orbifold with underlying space $W$, and with mirrors on the faces of $A_1, \ldots, A_n$. Then $V$ is a hyperbolic 3-orbifold with convex boundary, and there is a local isometry $i : V \to \mathbb{H}^3/\Gamma(P)$, with induced map $i_\ast : \pi orb_1(V) \to \Gamma(P)$, so that Image$(i_\ast) = G$. Since $V$ has convex boundary, every element in $\pi orb_1(V)$ is represented by a closed geodesic, and since $i$ takes geodesics to geodesics, it follows that $i$ is $\pi_1$-injective.

Note that $V$ is equivalent to a product orbifold $X \times I$, where $X$ is the 2-orbifold with reflector edges corresponding to one of the components of $\partial W - \bigcup A_i$. Thus $G = \text{image}(i_\ast)$ is isomorphic to the orbifold fundamental group of $X$.

The orientable double cover of $X$ is a 2-orbifold, $\tilde{X}$, where the underlying space is an orientable surface of genus $g$, and the cone points of $\tilde{X}$ all have order 2. If we identify $G$ with $\pi orb_1 X$, then the loops generating $F$ all lift to $\tilde{X}$, and so $F \subset \pi_1 \tilde{X}$. The group $\pi_1 \tilde{X}$ has a torsion-free subgroup, of index two (if the number of cone points is even) or four (if the number of cone points is odd), containing $F$. This is the surface subgroup we were looking for.
