Pd(OAc)$_2$-catalyzed dehydrogenative C–H activation:
An expedient synthesis of uracil-annulated β-carbolinones
Biplab Mondal$^1$, Somjit Hazra$^1$, Tarun K. Panda$^2$ and Brindaban Roy$^*$

Abstract
An intramolecular dehydrogenative C–H activation enabled an efficient synthesis of an uracil-annulated β-carbolinone ring system. The reaction is simple, efficient and high yielding (85–92%).

Introduction
The presence of a β-carbolinone skeleton in various natural products, such as secofascaplysin A (I), SL651498 (II) (Figure 1), and their remarkable biological and pharmacological properties make them stand out amongst all the carboline class of compounds [1-12]. For example, SL651498 was documented as a potential drug development candidate in a research program designed to discover subtype-selective GABA$\text{A}$ receptor agonists for the treatment of muscle spasms and generalized anxiety disorder [13]. β-Carbolinones such as strychnocarpine, the alkaloid from Alstonia venenata, and substituted 1-oxo-13-carbolines were also shown to have serotonin-receptor-binding activity (5-HT receptor) [14]. Moreover the natural and synthetic β-carbolines are also known to show anticancer activity against colon and lung cancers, and some β-carbolinones act as biological control agents for receptor research on bioenzyme inhibitors, such as the inhibition of HLE (human leukocyte elastase) [15-18].

Uracil, on the other hand, is one of the four nucleobases of RNA. It holds immense importance from a pharmaceutical and
biological point of view [19]. For example, 5-fluorouracil [20] and other uracil-based molecules [21-23] such as 3'-azido-3'-deoxythymidine (AZT), 2',3'-dideoxycytidine (DDC), (E)-5-[2-(bromovinyl)-2'-deoxyuridine] (BVDU), are active against cancer and the H1 virus [24-31].

Diverse approaches towards the synthesis of β-carbolinones have been developed [32-36], such as an intramolecular Heck reaction strategy of 2- and 3-iodoindoles for the synthesis of β- or γ-carbolinones by Beccalli et al. [32], AuCl₃ and Pd-catalyzed cycloisomerization of indole-2-carboxamides to β-carbolinones [33-35], Pd-catalyzed dehydrogenative annulation of indole-carboxamides with alkynes etc [36]. The development of metal-catalyzed C–H activation reaction has revolutionized the way a synthetic chemist now approaches a traditional C–C bond disconnection [32-44]. Dehydrogenative C–H activation [45-52] is the most elegant alternative in this endeavor as it avoids pre-functionalization of any C–H bond beforehand. But regioselectivity is the main problem in this type of reaction due to the ubiquitous presence of various C–H bonds in a simple organic molecule. However, sometimes the issue of regioselectivity can be resolved by the electronic property of the substrate itself. Pioneering work published by Fagnou et al. shows how a catalyst inverts its selectivity and reactivity between the coupling partners to achieve indole C3-arylation in a cross coupling reaction of an unactivated arene and N-acetylindole [53]. Driven by the same logic and guided by our previous work we envisioned that Pd(OAc)₂ would be an excellent starting point for catalyst screening. The amide 4a (R¹ = R² = R³ = R⁴ = Me) was used as a model substrate for this dehydrogenative coupling reaction. The reaction was set up in the presence of Pd(OAc)₂ (10 mol %), Cu(OAc)₂ (2 equiv) in DMF under open air at 70 °C (Table 1, entry 1). After 8 h we obtained 35% yield of 5a with 52% conversion of starting material. Increasing the temperature to 90 °C (Table 1, entry 2) afforded 63% yield of 5a with 80% conversion of 4a. Then different oxidants [Cu(OTf)₂, PhI(OAc)₂, K₂S₂O₈, (NH₄)₂S₂O₈, p-benzoquinone (BQ), oxone, AgOAc, molecular oxygen] were examined under these reaction conditions. With Cu(OTf)₂ (Table 1, entry 3) and oxone (Table 1, entry 8), total recovery of starting material was observed while PhI(OAc)₂ (Table 1, entry 4), (NH₄)₂S₂O₈ (Table 1, entry 6) showed total decomposition of starting material. With BQ the yield was almost the same (65%) as with Cu(OAc)₂ (Table 1, entry 7). The use of K₂S₂O₈ increased the yield of 5a to 83% (Table 1, entry 5) with complete conversion of starting material; AgOAc further increased the yield to 91% (Table 1, entry 9). Molecular oxygen also used as an oxidant resulted in a low 30% yield of 5a (Table 1, entry 10) with 51% conversion of 4a. Examination of different solvents led to determining that the polar solvents (DMF/DMSO (9:1), DMSO, DMAc, Table 1, entries 11, 12, 13) were far superior compared to non-polar solvent toluene (Table 1, entry 14). But the optimal result was obtained with the use of DMF (Table 1, entry 9). Testing the efficiency of other Pd catalysts for this reaction revealed that PdCl₂, i.e., Pd(0) did not show any catalytic activity (Table 1, entry 17). The yield decreased sharply for other Pd catalysts such as PdCl₂, Pd(CH₂CN)₂Cl₂ and

Results and Discussion
We started our investigation with the preparation of amide precursors 4 from N-substituted indole-2-carboxylic acids 1 (Scheme 1). The amides were treated with oxalyl chloride at room temperature [33] and the resulting acid chloride obtained was transformed to the amide by the reaction with amine 3 in dry THF using NaH as a base.

The amide precursor was then subjected to a series of reactions in pursuit of the best reaction conditions for the dehydrogenative coupling process. Assuming that the reaction goes through an electrophilic metatllation pathway, it was projected that Pd(OAc)₂ would be an excellent starting point for catalyst screening. The amide 4a (R¹ = R² = R³ = R⁴ = Me) was used as a model substrate for this dehydrogenative coupling reaction. The reaction was set up in the presence of Pd(OAc)₂ (10 mol %), Cu(OAc)₂ (2 equiv) in DMF under open air at 70 °C (Table 1, entry 1). After 8 h we obtained 35% yield of 5a with 52% conversion of starting material. Increasing the temperature to 90 °C (Table 1, entry 2) afforded 63% yield of 5a with 80% conversion of 4a. Then different oxidants [Cu(OTf)₂, PhI(OAc)₂, K₂S₂O₈, (NH₄)₂S₂O₈, p-benzoquinone (BQ), oxone, AgOAc, molecular oxygen] were examined under these reaction conditions. With Cu(OTf)₂ (Table 1, entry 3) and oxone (Table 1, entry 8), total recovery of starting material was observed while PhI(OAc)₂ (Table 1, entry 4), (NH₄)₂S₂O₈ (Table 1, entry 6) showed total decomposition of starting material. With BQ the yield was almost the same (65%) as with Cu(OAc)₂ (Table 1, entry 7). The use of K₂S₂O₈ increased the yield of 5a to 83% (Table 1, entry 5) with complete conversion of starting material; AgOAc further increased the yield to 91% (Table 1, entry 9). Molecular oxygen also used as an oxidant resulted in a low 30% yield of 5a (Table 1, entry 10) with 51% conversion of 4a. Examination of different solvents led to determining that the polar solvents (DMF/DMSO (9:1), DMSO, DMAc, Table 1, entries 11, 12, 13) were far superior compared to non-polar solvent toluene (Table 1, entry 14). But the optimal result was obtained with the use of DMF (Table 1, entry 9). Testing the efficiency of other Pd catalysts for this reaction revealed that PdCl₂, i.e., Pd(0) did not show any catalytic activity (Table 1, entry 17). The yield decreased sharply for other Pd catalysts such as PdCl₂, Pd(CH₂CN)₂Cl₂ and

| 18    | Pd(PPh<sub>3</sub>)<sub>2</sub>Cl<sub>2</sub> | AgOAc | DMF         | 90        | 40                          | 32                     |

All reactions were performed with 1 equiv starting material (4), 10 mol % Pd-catalyst, 2 equiv oxidant in 5 mL solvent at mentioned temperature, 8 h under open air. <sup>a</sup>Calculation on the basis of isolation of starting material. <sup>b</sup>Isolated yield.

Pd(PPh<sub>3</sub>)<sub>2</sub>Cl<sub>2</sub> presumably be due to the less electrophilic nature of these catalysts (Table 1, entries 15, 16, 18).

With the optimized reaction conditions in hand (10 mol % Pd(OAc)<sub>2</sub>, 2 equiv AgOAc in DMF at 90 °C for 8 h), we further explored the substrate scope of the reaction (Scheme 2).

All the reactions went very smoothly giving excellent yields in the range of (85–92%). No distinct steric influence was noticed when the indole-N-methyl group was replaced by ethyl, butyl or benzyl groups. However, the reaction did not proceed at all with the unsubstituted indole precursor (R<sub>1</sub> = H, 4m), this result may be explained with potential coordination of the Pd catalyst between the indole nitrogen and amide carbonyl oxygen. A representative X-ray crystal structure of β-carbolinone derivative 5h was obtained [57] (Figure 2).

The inactivity of Pd(0) (Table 1, entry 17), and inferior reactivity of other less electrophilic Pd catalysts indicates a mechanistic pathway that commence with electrophilic metalation at the indole C3 position. The nucleophilicity of indole at C3 is well known [58] and a similar kind of electrophilic reaction leads to the intermediate A (Scheme 3). We believe this inter-
mediate then undergoes a σ-bond metathesis reaction to form a seven-membered palladacycle $B$ which in turn produces the product β-carbolinones after reductive elimination from the 7-membered palladacycle $B$. The catalytic cycle is completed by AgOAc.

**Conclusion**

In conclusion we have developed an elegant method for the preparation of uracil annulated β-carbolinones via a high yielding dehydrogenative C–H activation process. The key to the success of this reaction is the complementary elec-
Electronic properties of the indole C3–H bond and the uracil C6–H bond. It is anticipated this efficient and atom economic approach can be emulated for the preparation of other β-carbolinones as well, and further results in this regard will be reported in due course.

Experimental
Representative procedure for the preparation of uracil annulated β-carbolinones (5a–m):

In a flame-dried round bottomed flask equipped with a magnetic bar, a mixture of 1 equiv starting material 4, 5 mL dry DMF, 2 equiv of AgOAc and 10 mol % Pd(OAc)₂ was taken and stirred at room temperature for 5 min. Then the reaction mixture was heated in an oil bath fixed at 90 °C for 8 h under air. Completion of the reaction was monitored by checking TLC. The reaction mixture was cooled to room temperature, diluted with water and 50 mL of EtOAc and passed through a pad of celite. The organic layer was washed with H₂O (2 × 10 mL) and saturated NaCl (aq) (1 × 10 mL). The organic part was washed with Na₂SO₄, evaporated and passed through a pad of celite. The organic layer was washed with H₂O (2 × 10 mL) and saturated NaCl (aq) (1 × 10 mL). The organic part was washed with Na₂SO₄, evaporated and purified by flash chromatography, using ethyl acetate/petroleum ether (2:8) as the eluent to afford product 5.
