Phosphatidylinositol 4-phosphate 5-kinase \( \alpha \) negatively regulates nerve growth factor-induced neurite outgrowth in PC12 cells

Tian Liu\(^1\),\(^2\),\(^3\) and Sang Yoon Lee\(^1\),\(^2\)

Neurite outgrowth, a cell differentiation process involving membrane morphological changes, is critical for neuronal network and development. The membrane lipid, phosphatidylinositol (PI) 4,5-bisphosphate (PIP2), is a key regulator of many important cell surface events of membrane signaling, trafficking and dynamics. This lipid is produced mainly by the type I PI 4-phosphate 5-kinase (PIP5K) family members. In this study, we addressed whether PIP5K\( \alpha \), an isoform of PIP5K, could have a role in neurite outgrowth induced by nerve growth factor (NGF). For this purpose, we knocked down PIP5K\( \alpha \) in PC12 rat pheochromocytoma cells by stable expression of PIP5K\( \alpha \) microRNA that significantly reduced PIP5K\( \alpha \) expression and PIP2 level. Interestingly, NGF-induced neurite outgrowth was more prominent in PIP5K\( \alpha \)-knockdown (KD) cells than in control cells. Conversely, add-back of PIP5K\( \alpha \) into PIP5K\( \alpha \) KD cells abrogated the effect of NGF on neurite outgrowth. NGF treatment activated PI 3-kinase (PI3K)/Akt pathway, which seemed to be associated with reactive oxygen species generation. Similar to the changes in neurite outgrowth, the PI3K/Akt activation by NGF was potentiated by PIP5K\( \alpha \) KD, but was attenuated by the reintroduction of PIP5K\( \alpha \). Moreover, exogenously applied PIP2 to PIP5K\( \alpha \) KD cells also suppressed Akt activation by NGF. Together, our results suggest that PIP5K\( \alpha \) acts as a negative regulator of NGF-induced neurite outgrowth by inhibiting PI3K/Akt signaling pathway in PC12 cells.

INTRODUCTION

Neurite outgrowth is a cellular process involved in neuronal migration, differentiation and plasticity.\(^1\) Neurite outgrowth is propagated through multiple steps of membrane remodeling such as formations of membranes protrusion and lamellipodia.\(^2\) These membrane structures are supported by actin cytoskeletal rearrangements. The Rho family of small guanosine triphosphatases, RhoA, Rac1 and Cdc42 that have critical roles in actin polymerization, function as primary regulators of neurite outgrowth.\(^3\),\(^4\) In addition, a number of studies have demonstrated that multiple signaling events, including phosphatidylinositol (PI) 3-kinase (PI3K) and its downstream effector Akt, MAPK and reactive oxygen species (ROS) generation, participate in the mediation of neurite outgrowth.\(^5\)–\(^9\)

Nerve growth factor (NGF) is a neurotrophin crucial for neuronal growth and survival. NGF is also a potent inducer of neurite outgrowth.\(^1\),\(^10\) NGF binds to the tyrosine kinase receptor TrkA, triggering activation of various signaling pathways including PI3K/Akt, phospholipase C and Ras/Raf/MAPK cascades.\(^6\),\(^10\)–\(^13\) PC12 cells derived from pheochromocytoma of the rat adrenal medulla have been widely used as a model system for studies of NGF-induced neurite outgrowth. Following NGF treatment, these cells stop dividing and show terminally differentiated neuronal phenotype.

PI 4,5-bisphosphate (PIP2), a membrane lipid enriched in the plasma membrane, is generated mainly by the type I PI 4-phosphate 5-kinase (PIP5K) family members comprising three isoforms, PIP5K\( \alpha \), PIP5K\( \beta \) and PIP5K\( \gamma \).\(^14\),\(^15\) PIP2 is a key regulator of membrane signaling and trafficking, and actin cytoskeletal reorganization.\(^14\),\(^16\),\(^17\) It was previously shown that overexpression of PIP5K\( \beta \) (in this study, the previous mouse and rat PIP5K\( \beta \) is referred to as PIP5K\( \alpha \), and vice versa,
Inhibition of neurite outgrowth by PIP5K\textsubscript{a}  
T Liu and SY Lee

according to the revised nomenclature in the current GenBank database\textsuperscript{17} in mouse N1E-115 neuroblastoma cells induced neurite retraction and cell rounding, while overexpression of its catalytically inactive mutant promoted neurite extension.\textsuperscript{18,19} The signaling pathway of RhoA and its downstream effector p160 Rho-associated coiled-coil-forming protein kinase (ROCK) is known to mediate neurite retraction. RhoA/ROCK functioned upstream of PIP5K\textsubscript{a} in the PIP5K\textsubscript{b}–induced neurite retraction.\textsuperscript{18,19}

However, a functional role of PIP5K\textsubscript{a} and PIP2 in NGF–dependent neurite growth remains unaddressed. In this study, we aimed to determine whether PIP5K\textsubscript{a}, another isoform of PIP5K, has a regulatory role in neurite outgrowth elicited by NGF. Here, we present evidence that PIP5K\textsubscript{a} acts to inhibit NGF-induced neurite outgrowth by negatively regulating PI3K/Akt signaling pathway in a PIP2-dependent manner.

**MATERIALS AND METHODS**

**Materials**

Most research chemicals, including Dulbecco’s modified Eagle’s medium, basicfleid, N-acetyl-l-cysteine and paraformaldehyde, were purchased from Sigma-Aldrich (St Louis, MO, USA). Fetal bovine serum and penicillin/streptomycin were obtained from Hyclone (Logan, UT, USA). NGF (murine 2.5S) was purchased from Promega (Madison, WI, USA). LY294002 was from Biomol (Plymouth Meeting, PA, USA). Goat polyclonal antibodies to PIP5K and β-actin were obtained from Santa Cruz Biotechnology (Santa Cruz, CA, USA). Rabbit polyclonal antibodies to Akt and phospho-Akt (Ser473), and mouse mAb to Myc were obtained from Cell Signaling Technology (Beverly, MA, USA). Lipofectamine 2000, Opti-MEM I, dihydroethidium (DHE) and horse serum were from Invitrogen (Carlsbad, CA, USA). PC12 rat pheochromocytoma cell line was a gift from Haeyoung Suh-Kim (Ajou University). Expression plasmids of Myc–PIP5K\textsubscript{a} and monomeric red fluorescence protein (mRFP)–PI3K\textsubscript{a} were described previously.\textsuperscript{20}

**Cell culture and treatment**

PC12 rat pheochromocytoma cells were maintained in Dulbecco’s modified Eagle’s medium supplemented with 10% fetal bovine serum, 5% horse serum and penicillin/streptomycin at 37°C in a humidified atmosphere of 5% CO\textsubscript{2} in air. Cells were serum starved overnight and then treated with 100 ng ml\textsuperscript{-1} NGF. In case of experiments with LY294002 or blasticidin, cells were pretreated from Cell Signalling Technology (Beverly, MA, USA). Lipofectamine 2000, Opti-MEM I, dihydroethidium (DHE) and horse serum were from Invitrogen (Carlsbad, CA, USA). PC12 rat pheochromocytoma cell line was a gift from Haeyoung Suh-Kim (Ajou University). Expression plasmids of Myc–PIP5K\textsubscript{a} and monomeric red fluorescence protein (mRFP)–PI3K\textsubscript{a} were described previously.\textsuperscript{20}

**Stable knockdown (KD) of PIP5K\textsubscript{a}**

A PC12 cell line stably expressing PIP5K\textsubscript{a} microRNA (miR) was generated using BLOCK-iT Pol II miR RNAi Expression Vector Kits (Invitrogen) according to the manufacturer’s instructions. Synthesized oligonucleotides (Genotech, Daejeon, Korea) harboring the rat PIP5K\textsubscript{a} sequence (NM_001042621, 546 amino acids), 5’–TGCAGCTACATGTCAGTGGCCAAAACATAAGTGAGGGTTCAC, A was transfected with the PIP5K\textsubscript{a} miR expression vector, PC12 cells were transfected with the PIP5K\textsubscript{a} miR expression plasmid by Amaxa Nucleofection using a Cell Line Nucleofector Kit V (Amaxa Biosystems, Cologne, Germany) following the manufacturer’s protocol and cultured in growth medium supplemented with 5 μg ml\textsuperscript{-1} blasticidin. Blasticidin-resistant cells expressing EmGFP, visualized by Axiovert 200M inverted microscope (Carl Zeiss Microimaging, Göttingen, Germany), were selected for 3 weeks. As a negative control, a pcDNA 6.2-GW/EmGFP-miR neg control plasmid, supplied by the manufacturer, was stably expressed in the same manner.

**Western blot analysis**

Cell lysates (30–40 μg) prepared in a lysis buffer (50 mM Tris pH 7.4, 150 mM NaCl, 1 mM EDTA, 1 mM EGTA, 1 mM dithiothreitol, 1 mM Na\textsubscript{3}VO\textsubscript{4}, 5 mM NaF and 1% Triton X-100) were separated by SDS-PAGE and transferred to nitrocellulose membranes. Following blocking with 5% nonfat milk solution, membrane blots were probed with primary antibodies against PIP5K\textsubscript{a}, Akt, phospho-Akt (Ser473), Myc tag or β-actin and then with horseradish peroxidase-conjugated secondary antibodies (Zymed Laboratories, San Francisco, CA, USA). The immune complexes were visualized using enhanced chemiluminescence detection system (Santa Cruz Biotechnology).

**Neurite outgrowth**

PC12 cells were seeded into 6-well plates at a low density and then serum starved overnight. After NGF treatment under the indicated time periods, bright field images were acquired using an Axiovert 200M inverted microscope for the detection of neurites. Neurite length was determined by image analysis using AxioVision LE software (Carl Zeiss Microimaging).

**PIP5K\textsubscript{a} transfection**

Myc–PIP5K\textsubscript{a}, mRFP–PI3K\textsubscript{a} or corresponding empty vectors were mixed with Lipofectamine 2000 in Opti-MEM I according to the supplier’s protocol, and added to the PIP5K\textsubscript{a} KD cells. Twenty-four hours post transfection, Myc–PIP5K\textsubscript{a} and mRFP–PI3K\textsubscript{a} transfection samples were processed for western blot analysis and cell imaging, respectively. For imaging of mRFP–PIP5K\textsubscript{a}, cells were washed twice with filtered phosphate-buffered saline and fixed with 4% paraformaldehyde for 15 min at ambient temperature. mRFP fluorescence was visualized using an Axiovert 200M inverted microscope.

**PPIP2 immunostaining**

PPIP2 immunocytochemistry was performed as described previously.\textsuperscript{20} Briefly, cells were fixed with 4% paraformaldehyde and permeabilized with 0.5% saponin for 15 min each at room temperature. After blocking with 10% goat serum in theta burst stimulation for 30 min at 37°C, the cells were sequentially incubated with anti-PPIP2 mouse IgM mAb (Echelon Biosciences, Salt Lake City, UT, USA), biotinylated goat anti-mouse IgM (Jackson ImmunoResearch Laboratories, West Grove, PA, USA) and Alexa Fluor 594-conjugated streptavidin (Invitrogen). Each immunostaining step was performed for 1 h at 37°C and followed by washing with theta burst stimulation containing 1% goat serum. Cells were visualized using an Axiovert 200M inverted microscope.

**Detection of intracellular ROS**

Cells were preincubated with DHE, a ROS-specific fluorescent dye at 37°C. After washing three times with phosphate-buffered saline, fresh growth media containing NGF were added to the cells. Then, the DHE fluorescent images were immediately captured using Axiovert 200M inverted microscope.
Intracellular delivery of PIP2

Intracellular delivery of PIP2 was performed as described previously.20 In brief, dioctanoyl–PIP2, a water-soluble analog of PIP2, was mixed with histone as a shuttle PIP carrier (Echelon Biosciences) at a 1:1 molar ratio for 20 min at room temperature. The mixture was diluted with serum-free medium and added to the serum-starved PIP5Kα KD cells for 1 h before NGF treatment.

Reverse transcription–PCR

Complementary DNA was synthesized from isolated total RNA according to the previously described procedures.20 The sense and antisense primers of rat PIP5Kα and glyceraldehyde-3-phosphate dehydrogenase were used for PCR amplification. The following specific oligonucleotide primers (Bioneer, Daejeon, Korea) were used: 5′-GTGAAAGGAGCAATCTGACCC-3′ (sense) and 5′-CGGCAGCAGTTGTTCATCAG-3′ (antisense) for rat PIP5Kβ; 5′-GTACTCACTGTCAACTTGCAGTAAGC-3′ (sense) and 5′-GTCAGAGTCAAGTAGCAGC-3′ (antisense) for rat PIP5Kγ. Amplified PCR products were separated by electrophoresis on 1.5% agarose gels and detected under ultraviolet light. Gel images were obtained using the Gel Doc molecular imaging system (Bio-Rad Laboratories, Hercules, CA, USA).

Density quantification and statistical analysis

The band intensities of western blots and PCR products were measured using NIH ImageJ software (NIH, Bethesda, MD, USA). Statistical significance of data shown in the graphs was determined using an unpaired two-tailed t-test (Graphpad Software, San Diego, CA, USA) and data are presented as mean ± s.e.m. *P<0.01.

RESULTS

PIP5Kα KD promotes NGF-induced neurite outgrowth

To examine a role for PIP5Kα in NGF-induced neurite outgrowth, we first developed PIP5Kα-KD PC12 cell lines using miR expression system. Complementary oligonucleotides corresponding to the PIP5Kα target sequence (1844–1864 bp) were cloned into a pcDNA 6.2-GW/EmGFP-miR expression vector that contains EmGFP, a variant of enhanced GFP, as a reporter. As a negative control, a pcDNA 6.2-GW/EmGFP-miR-neg control plasmid harboring complementary oligonucleotides that do not target mammalian genes was also used. PC12 cells transfected with the PIP5Kα miR- or negative control miR-expressing plasmids were selected by treatment with blasticidin. Stable expression of both plasmids was confirmed by the presence of EmGFP fluorescence (Figure 1a). PIP5Kα miR significantly reduced of protein PIP5Kα mRNA (Figures 1b and d) and protein (Figures 1c and d) expression levels compared with the control miR, as demonstrated by reverse transcription–PCR and western blot analysis, respectively. PIP5Kβ and PIP5Kγ mRNA levels were not affected by PIP5Kα miR (Figure 1b), indicating its specific action on PIP5Kα.

We then measured neurite outgrowth in the absence or presence of NGF in the control and PIP5Kα KD cells. As expected, neurite outgrowth was clearly observed 24 and 48 h after NGF treatment in a time-dependent manner (Figure 2a). Notably, we found that NGF-induced neurites were more...

PIPIKz KD facilitates NGF-induced activation of PI3K/Akt pathway and ROS generation

We tested whether Akt activation was responsible for the enhanced neurite outgrowth observed in PIP5Kz KD cells. Phosphorylation of Akt (Ser473) by NGF in PIP5Kz KD cells was much higher than that in control cells (Figures 3a and b). PIP5Kz KD also led to significant increase in Akt phosphorylation even in the NGF-un-treated condition (Figures 3a and b). As Akt activation is dependent on PI3K activity, we tested the effect of PI3K inhibitor LY294002 on the NGF-induced Akt phosphorylation. Pretreatment of PIP5Kz KD cells with LY294002 strongly inhibited Akt phosphorylation by NGF (Figure 3c). These results suggest that PIP5Kz KD facilitates NGF-induced activation of PI3K/Akt pathway and ROS generation.

Reconstituted expression of PIP5Kz attenuates NGF-induced neurite outgrowth and Akt activation

Next, we examined whether complementation of PIP5Kz KD cells with PIP5Kz could inhibit NGF-induced neurite outgrowth. To test this, we transfected PIP5Kz KD cells with mRFP empty vector or mRFP–PIP5Kz and measured changes in neurite outgrowth in the absence or presence of NGF. As expected, NGF-induced neurite outgrowth was observed in the mRFP-transfected and mRFP–PIP5Kz-untransfected cells (Figure 5a). In contrast, however, expressed mRFP–PIP5Kz that partially localized to the cell surface\(^{15}\) significantly blocked neurite outgrowth by NGF (Figure 5a). We then measured the effect of reconstituted expression of PIP5Kz on Akt activation by NGF. PIP5Kz KD cells were transfected with Myc–PIP5Kz or Myc control vector. Overexpression of Myc–PIP5Kz was confirmed by Myc tag immunoreactivity (Figure 5b). The magnitude of NGF-induced increase in Akt phosphorylation was much lower in the Myc–PIP5Kz-transfected cells than in the vector-transfected cells (Figures 5b and c). These results indicate an inhibitory role of PIP5Kz in NGF-induced neurite outgrowth and Akt activation.

Delivery of PIP2 interferes with NGF-induced Akt phosphorylation

We then examined whether the inhibitory effects of PIP5Kz on NGF-induced Akt phosphorylation could be attributable to its lipid product, PIP2. We first measured difference in PIP2 levels in control and PIP5Kz KD cells using immunocytochemistry with an antibody against PIP2. As expected, the plasma membrane PIP2 levels were significantly reduced in PIP5Kz KD cells compared with those in control cells (Figure 6a). Then, we supplemented the PIP2 levels by employing a method of intracellular deliver of PIP2. Exogenous sources of PIP2 mixed with shuttle carriers such as polyamine and histone were successfully internalized into mammalian cells across the plasma membrane.\(^{24}\) We added a similar complex of dioctanoyl–PIP2 and histone as a carrier to PIP5Kz KD cells before NGF treatment. As demonstrated by the PIP2 immunostaining result, the PIP2 delivery resulted in increased PIP2 levels (Figure 6b). The exogenously applied PIP2 also resulted in a blunted Akt phosphorylation by NGF (Figures 6c and d).
DISCUSSION

In this study, we pursued functional roles for PIP5Kz and PIP2 in NGF-dependent neurite growth using a PC12 cell model. Gene KD or overexpression of PIP5Ks that causes changes in plasma membrane PIP2 levels has been widely used for demonstrating their physiological roles in a variety of biological events. Using such manipulation of PIP5Kz, we found that PIP5Kz KD increased and reconstituted PIP5Kz expression decreased the neuritogenic activity of NGF in PC12 cells. We further showed that PIP5Kz deficiency potentiated NGF-induced Akt phosphorylation, which was reversed by the reconstituted PIP5Kz expression. Thus, our results support an idea that newly synthesized PIP2 by PIP5Kz in the plasma membrane may desensitize PI3K/Akt signaling pathway, which in turn negatively regulates NGF-induced neurite outgrowth. Phosphorylation and activation of Akt that is mediated via phosphoinositide-dependent kinase 1 contributes to NGF-induced neurite outgrowth.8 PI3K-catalyzed generation of PI 3,4,5-trisphosphate (PIP3) from PIP2 is required for the phosphoinositide-dependent kinase 1-mediated Akt phosphorylation. PI3K/Akt signaling has an important role in neurite branching and elongation.4,8 An increase in local PIP3 production in the plasma membrane through a positive-feedback loop between PI3K and Rac1/Cdc42 was important for neurite outgrowth induced by NGF.4,25

Generally, PIP3 remains very low in the resting condition and undergoes elevation upon stimulation. The increased PIP3 level is rapidly hydrolyzed back to PIP2 by the PTEN (phosphate and tensin homolog) that acts as a PIP3 3-phosphatase. In addition, SHIP2 (Src homology 2 domain-containing inositol phosphatase 2) and PIPP (proline-rich inositol polyphosphate 5-phosphatase) that mediate PIP3 hydrolysis to PI 3,4-bisphosphate also reduce PIP3 level. PTEN as well as SHIP2 and PIPP were shown to prevent the

Generally, PIP3 remains very low in the resting condition and undergoes elevation upon stimulation. The increased PIP3 level is rapidly hydrolyzed back to PIP2 by the PTEN (phosphate and tensin homolog) that acts as a PIP3 3-phosphatase. In addition, SHIP2 (Src homology 2 domain-containing inositol phosphatase 2) and PIPP (proline-rich inositol polyphosphate 5-phosphatase) that mediate PIP3 hydrolysis to PI 3,4-bisphosphate also reduce PIP3 level. PTEN as well as SHIP2 and PIPP were shown to prevent the
NGF-induced neurite outgrowth in PC12 cells, indicating a positive correlation between PIP3 level and neurite outgrowth. Interestingly, accumulating evidence has demonstrated that PTEN harbors a PIP2-binding motif in the N-terminal region, and the interaction with PIP2 induces its conformational change, promoting membrane targeting and the lipid phosphatase activity of PTEN. It is well established that PTEN negatively regulates PI3K/Akt signaling pathway and neurite outgrowth by reducing PIP3 level. Moreover, the increased Akt activity by heat shock treatment was reduced by the presence of PIP2. Overexpression of PIP5K-like1 (the fourth member of the type I PIP5Ks) showed an inhibitory effect on Akt phosphorylation.

Given these reports, one may consider the possibility that PIP5K-dependent PIP2 formation allows PTEN to become more active, resulting in decrease in PIP3 level, which attenuates NGF-induced PI3K/Akt signaling and neurite outgrowth. The detailed molecular mechanisms by which PIP5Kα-derived PIP2 mediates inhibitory effects on PI3K/Akt signaling pathway require further investigation.

Phosphoinositides and their metabolizing enzymes are key factors for controlling cell polarity involving membrane remodeling processes, such as neurite outgrowth and chemotaxis. In chemotaxis of neutrophils and Dictyostelium, PTEN and PIP2 localize to the rear of cells, whereas PIP3 and PI3K are spatially restricted to the front of the leading edges. Activation of phospholipase C-mediated PIP2 degradation resulted in downregulation of PIP2-dependent PTEN activity, resulting in increased PIP3 level at the leading edge in the chemotaxing cells. In this context, it is plausible that PIP5Kα KD, which can also deplete PIP2 level like the action of phospholipase C, can enhance neurite outgrowth.

Rho family small guanosine triphosphatases that coordinate cytoskeletal membrane remodeling also have an important role in the neurite outgrowth. Rac1 and Cdc42, the critical regulators of actin and microtubule dynamics, localize to the tips of axons together with PI3K and induce axonal elongation. On the other hand, activation of RhoA and ROCK strongly inhibits neurite outgrowth. Accordingly, inhibition of the RhoA/ROCK pathway has been recognized as a promising therapeutic target for inducing axonal growth.

ROS scavenging or inhibiting NADPH oxidase-specific ROS that reduced ROS levels suppressed neurite extension. Epidermal growth factor-induced activation of Akt was dependent on increased intracellular ROS levels and activation of Akt and ROS generation.
ROS, NGF stimulation also evoked ROS, and the NGF-induced neurite outgrowth was prevented by N-acetyl-L-cysteine in PC12 cells. PIP2 formation by PIP5K activity was decreased in response to hydrogen peroxide treatment in the sarcolemma plasma membranes. Conversely, PIP5KKD decreased gene expression of antioxidant enzymes such as heme oxygenase-1, suggesting that PIP2 may retain an ability to suppress intracellular ROS. Overall, our results suggest that increase in NGF-induced ROS underlies activation of Akt, which can be facilitated by deficiency of PIP5Kα.

Previously, PIP5Kβ was demonstrated to act as a downstream effector of RhoA/ROCK signaling pathway that makes a primary contribution to the neurite retraction. The antineuritogenic effect of PIP5Kβ depended on its lipid kinase activity. Considering previous observations that the type I PIP5K family members are activated by RhoA, we cannot exclude the possibility that PIP5Kα-driven PIP2 pool also participates in the RhoA/ROCK-mediated neurite retraction. In this regard, it is intriguing to consider that a deficiency of PIP5Kα-lowering PIP2 level renders RhoA/ROCK signaling pathway ineffective, thereby promoting neurite outgrowth. On the other hand, whether PIP5Kβ has a similar role to PIP5Kα in the regulation of NGF-induced neurite outgrowth needs to be studied.

In the central nervous system, embryonic neurons are morphologically changed into a specialized form having multiple dendrites and an axon. The neuronal differentiation involving neurite outgrowth is important for synapse formation during development and also for axon regeneration following neuronal damages. In response to diverse extracellular cues such as chemoattractants and chemorepellents, axons undergo directional elongations or retractions that are related to their maturation and polarization. Although further studies will be necessary to fully elucidate underlying mechanisms of the antineuritogenic actions of PIP5Kα-driven PIP2, this study provides novel insight into the regulatory roles of PIP5Kα in NGF-induced neurite outgrowth.
