Abstract

We calculate the hadronic tensor for inclusive semileptonic $B \rightarrow X_c \ell \bar{\nu}$ decay to $O(\alpha_s)$. This allows $O(\alpha_s \Lambda_{\text{QCD}}/m_b)$ corrections to hadronic invariant mass observables to be directly evaluated with experimentally required cuts on phase space. Several moments of phenomenological interest are presented to order $O(\alpha_s \Lambda_{\text{QCD}}/m_b)$ and $O\left(\Lambda_{\text{QCD}}^3/m_b^3\right)$, allowing a consistent extraction of the HQET parameters up to $O\left(\Lambda_{\text{QCD}}^3/m_b^3\right)$ and the $b$ quark mass with theoretical error $\sim 50\text{MeV}$. The hadronic invariant mass spectrum is examined with a general moment to obtain observables that test the theoretical error estimate assigned to these parameters; in particular, fractional moments that directly test the OPE for inconsistencies in the hadronic invariant mass spectrum are reported. The $m_b \Lambda_{\text{QCD}}/m_c^2$ expansion present for fractional moments of the hadronic invariant mass spectrum is discussed and shown to introduce a numerically suppressed uncertainty of $O\left(m_b^4 \Lambda_{\text{QCD}}^4 / m_c^8\right)$.

I. INTRODUCTION

Inclusive semileptonic $B \to X_c \ell \bar{\nu}$ decay offers an opportunity to measure the Cabibbo-Kobayashi-Maskawa (CKM) parameter $|V_{cb}|$ and the bottom quark mass \cite{1, 2, 3, 4, 5, 6, 7, 8, 9}. Measurements of these parameters are crucial to the $B$ factory program of over-constraining the CKM sector of the standard model \cite{10}. Experimental studies of moments of the differential decay spectrum of $B \to X_c \ell \bar{\nu}$ combined with a measurement of the total inclusive decay rate are useful in extracting these parameters, as these observables can be measured cleanly by experiment, and calculated from QCD without model dependence using an operator product expansion (OPE).

The OPE is an expansion in powers of the ratio $\Lambda_{QCD}/m_b$, where the terms in this expansion are parameterized using heavy quark effective theory (HQET). The OPE demonstrates that in the $m_b \to \infty$ limit, inclusive $B$ meson decay spectra are equal to $b$ quark decay spectra. To extract $m_b$ and $|V_{cb}|$ from the inclusive decay spectrum with high precision, one needs to accurately know the relevant matrix elements of terms in the OPE that the spectrum depends upon. Extensive theoretical effort has been devoted to calculating the decay rates and moments of various spectra; to test HQET by the extractions of these non-perturbative parameters from different spectra, and to obtain $|V_{cb}|$ and a precise value for the $b$ quark mass.

Experimental results have been reported by the BABAR, CLEO and DELPHI collaborations measuring various $B$ meson decay spectra and moments \cite{11, 12, 13, 14, 15, 16}. Recent analysis of this data \cite{17, 18} finds $|V_{cb}| = (40.8 \pm 0.9) \times 10^{-3}$ and $m_b^{1S} = 4.74 \pm 0.10$ GeV, where the experimental uncertainties dominate the extraction. As the experimental errors are expected to decrease in the near future, it is appropriate to reexamine the theoretical error assigned in this extraction. The largest contributions to the theoretical uncertainties introduced in these fits come from the estimated size of the $\mathcal{O}(\alpha_s \Lambda_{QCD}/m_b)$ corrections with a lepton energy cut, the $\mathcal{O}(\alpha_s \Lambda^2_{QCD}/m_b^2)$ terms, and the $\mathcal{O}(\Lambda^4_{QCD} / m_b^2 m_c^2)$ terms introduced due to the HQET expansion employed for $m_c$ \cite{19}.

In past calculations, the lepton energy cut dependence of the $\mathcal{O}(\alpha_s \Lambda_{QCD}/m_b)$ terms was not calculated, and these terms were treated as a source of error in the determination of $m_b$ and $|V_{cb}|$. In this paper, we improve upon past results by calculating the lepton energy cut dependence of the $\mathcal{O}(\alpha_s \Lambda_{QCD}/m_b)$ terms. With the calculation of these terms and the
moments presented in this paper, global fits will allow precise determinations of $|V_{cb}|$ and $m_b$ to occur from the inclusive decay spectrum.

As the precision of determinations of $m_b$ and $|V_{cb}|$ improves, it becomes important to test the consistency of the OPE more precisely. Observables that do not depend strongly on the nonperturbative parameters that introduce the dominant uncertainty in extractions of $m_b$ and $|V_{cb}|$ allow one to test if the uncertainty assigned for all higher order terms in the OPE is sufficiently large. By examining a general moment of the lepton spectrum [20], observables of this type, called OPE testing moments, have been found. In this paper, we apply this technique to hadronic invariant mass moments. By testing the error assigned to higher order effects experimentally we improve the confidence in the theoretical error assigned due to these effects in determinations of $m_b$ and $|V_{cb}|$ from moments of semileptonic inclusive $b$ decay. This allows extractions of $m_b$ from these decay to occur in a relatively theoretically clean and unambiguous fashion [21]. These results can be combined with the results for the lepton energy spectrum for cross checks and fits to determine the HQET parameters.

The structure of this paper is as follows. In Section II the $O(\alpha_s)$ contribution to the hadronic tensor is presented. Section III reports on moments in the 1S mass scheme [22, 23, 24, 25], and discusses the $m_b \Lambda_{QCD}/m_c$ expansion present in fractional hadronic invariant mass moments. The decay width to $O(\alpha_s \Lambda_{QCD}/m_b)$ and $O(\Lambda_{QCD}^3/m_b^3)$ and the error that should be assigned in the fit of the moments presented in this paper is discussed. The dominant parameters affecting the extraction of $|V_{cb}|$ inclusively, $m_{b}^{1S}$ and $\lambda_1$, are extracted from known moments. Observables appropriate to precisely test the consistency of the OPE are reported and moments that allow a measurement of the $b$ quark mass with minimal theoretical error due to unknown matrix elements are presented.

II. $O(\alpha_s)$ CONTRIBUTION TO DECAY SPECTRUM

A. Hadron Tensor Decomposition

The $O(\alpha_s)$ corrections to semileptonic $B \to X_c \ell \bar{\nu}$ decay have been known for particular spectra and moments for some time [26, 27, 28]. The decomposition of the triple differential decay spectrum in terms of structure functions has not appeared in the literature to date, although the limit of this spectrum appropriate for a massless final state is known [29]. The
triple differential decay spectrum must be known to allow for the experimentally required
cuts on the kinematic variables to be imposed in calculating the \( \mathcal{O}(\alpha_s \Lambda_{\text{QCD}}/m_b) \) terms and
to perform a general moment analysis, and so we present it here.

We decompose the triple differential decay spectrum in terms of the invariant mass of the
\( W \) boson \( \hat{y} = q^2/m_b^2 \) where \( q^\mu \) is the momentum of the lepton pair, the \( c \) quark jet invariant
mass \( \hat{z} = (m_b v - q)^2/m_b^2 \), and the charged lepton energy \( \hat{E}_\ell = E_\ell/m_b \). This spectrum is
written in terms of a lepton tensor \( L_{\mu\nu} \) and the hadron tensor \( W^{\mu\nu} \),

\[
\frac{1}{\Gamma_0} \frac{d\Gamma}{\hat{y} d\hat{z} d\hat{E}_\ell} = W^{\mu\nu}(\hat{y}, \hat{z}) L_{\mu\nu}(\hat{y}, \hat{z}, \hat{E}_\ell),
\]

where

\[
\Gamma_0 = \frac{G_F^2 |V_{cb}|^2 (m_b^{\text{pole}})^5}{192\pi^3}.
\]

Integrating over the charged lepton energy the differential decay spectrum becomes

\[
\frac{1}{\Gamma_0} \frac{d\Gamma}{\hat{y} d\hat{z} d\hat{z}} = 12 E_0 t W_{\mu\nu}(\hat{y}, \hat{z}) L_{\mu\nu}(\hat{y}, \hat{z}),
\]

where \( E_0 = 1/2 \left( 1 + \hat{z} - \hat{y} \right) \) is the leading order energy of the \( c \) quark jet, \( \rho = m_c^2/m_b^2 \) and
\( t = \sqrt{1 - \hat{z}/E_0^2} \) is the rapidity of the \( c \) quark.

The hadron tensor can be decomposed in terms of the initial \( B \) meson four momentum \( Q^\mu \)
and the hadronic decay products four momentum \( P^\mu = Q^\mu - q^\mu \), where \( q^\mu \) is the momentum of
the lepton pair. This tensor can be calculated from the discontinuity of the time ordered
product of the current \( J_\mu = \bar{c}\gamma_\mu(1 - \gamma_5)b \),

\[
W^{\mu\nu} = \frac{1}{\pi \Gamma_0} \text{Im} \left[ i \int d^4x e^{i(P - m_b v)\cdot x} \langle \bar{B}|T[J^{\mu}(x), J^{\nu}(0)]|B \rangle \right].
\]

This tensor is calculated by considering the quark-gluon level processes involved in this
decay. The spectra obtained from the parton level discontinuity are expected to accurately
describe physical \( B \) meson decay spectra so long as observables are sufficiently inclusive.

The tensor decomposition in terms of the four vectors \( Q^\mu \) and \( P^\mu \) yields five non trivial
structure functions \( W_i \),

\[
W^{\mu\nu}(\hat{y}, \hat{z}) = W_1(\hat{y}, \hat{z}) \left( P^{\mu} Q^{\nu} + P^{\nu} Q^{\mu} - P \cdot Q g^{\mu\nu} + i\epsilon^{\mu\nu\alpha\beta} Q_\alpha P_\beta \right) - W_2(\hat{y}, \hat{z}) g^{\mu\nu} + W_3(\hat{y}, \hat{z}) Q^{\mu} Q^{\nu} + W_4(\hat{y}, \hat{z})(P^{\mu} Q^{\nu} + P^{\nu} Q^{\mu}) + W_5(\hat{y}, \hat{z}) P^{\mu} P^{\nu}.
\]
The operator product expansion of the structure functions is known to $O\left(\Lambda_{QCD}^{2}/m_{b}^{2}\right)$ \cite{1, 2, 3, 9}. There are two nonperturbative parameters at $O\left(\Lambda_{QCD}^{2}/m_{b}^{2}\right)$ labelled $\lambda_{1,2}$ and six parameters at order $O\left(\Lambda_{QCD}^{3}/m_{b}^{3}\right)$, labelled $\tau_{1,2,3,4}$ and $\rho_{1,2}$ the definitions of which can be found in \cite{9}.

\section*{B. $O(\alpha_s)$ Contributions to Hadron Tensor Structure Functions}

The hadronic structure functions $W_{i}$ in Eq. \cite{9} have the perturbative expansion:

$$W_{i}(\hat{y}, \hat{z}) = W_{i}^{0}(\hat{y}, \hat{z}) + \frac{C_{F} \alpha_{s}}{4 \pi} W_{i}^{1}(\hat{y}, \hat{z}) + O\left(\alpha_{s}^{2}\right).$$  \hspace{1cm} (6)

The $O(\alpha_{s})$ contributions to the structure functions are calculated by taking all cuts across all intermediate state contributions to the diagrams shown in Fig. \ref{fig:diagrams}. Combined with the external quark wave-function renormalization this gives the $W_{i}^{1}$. At tree level, in the massless final state limit only $W_{i}^{0}$ is nonzero. $W_{i}^{1}$ can be expressed as

$$W_{1}^{1}(\hat{y}, \hat{z}) = W_{1a}^{1}(E_{0}, t, \hat{z}, \hat{y}) \delta(\hat{z} - \rho) + W_{1b}^{1}(E_{0}, t, \hat{z}) \theta(\hat{z} - \rho) + W_{1c}^{1}(E_{0}, t, \hat{z}, \lambda_{G}^{2}),$$  \hspace{1cm} (7)
where

\[
W_{1a}^1(E_0, t, \hat{z}, \hat{y}) = -16 - \frac{2}{t} \log^2 \left( \frac{1 + t}{1 - t} \right) - \frac{4}{t} \log \left( \frac{1 + t}{1 - t} \right) \log (\rho) \\
+ \left( \frac{4 (1 + \rho)}{\hat{y} t} - \frac{12 E_0}{\hat{y} E_0 t} + \frac{4 \rho}{\hat{y} E_0 t} \right) \log \left( \frac{1 + t}{1 - t} \right) + \frac{(2 - 8E_0 + 6 \rho)}{\hat{y}} \log (\rho) \\
+ \frac{8}{t} \text{Li}_2 \left( \frac{2 E_0 t}{E_0 (t - 1) + 1} \right) - \frac{8}{t} \text{Li}_2 \left( \frac{2 E_0 t}{E_0 (1 + t) - \rho} \right) \\
- \frac{8}{t} \left( \log \left( \frac{1 + t}{1 - t} \right) + \log (\rho) \right) \log \left( \frac{1 + (t - 1) E_0}{\sqrt{\hat{y}}} \right),
\]

\[
W_{1b}^1(E_0, t, \hat{z}) = -\frac{2 (1 + \hat{z}) (\hat{z} - \rho)}{E_0^2 t^2} - \frac{2 (5 \hat{z} - \rho)}{E_0 t^2} \frac{2 (3 \hat{z} + \rho)}{z^2 t^2} \\
- \left( \frac{4}{E_0 t^2} - \frac{(\hat{z} - \rho + 4)}{E_0^2 t^2} + \frac{(\hat{z} - \rho)}{E_0^3 t^2} \right) \frac{1}{t} \log \left( \frac{1 + t}{1 - t} \right),
\]

\[
W_{1c}^1(E_0, t, \hat{z}, \lambda_G^2) = -\left( 16 - \frac{8}{t} \log \left( \frac{1 + t}{1 - t} \right) \right) \log(\lambda_G) \delta(\hat{z} - \rho) \\
- \theta \left( \hat{z} - (\sqrt{\rho} + \lambda_G)^2 \right) \frac{8 \rho f_1}{\hat{z} \left( \hat{z} - \rho + \lambda_G^2 \right)^2} - \theta \left( \hat{z} - (\sqrt{\rho} + \lambda_G)^2 \right) \frac{8 f_1}{f_2} \\
+ \theta \left( \hat{z} - (\sqrt{\rho} + \lambda_G)^2 \right) \frac{8 \log \left( \frac{\hat{z} + \lambda_G^2 - \rho + f_1 t}{\hat{z} + \lambda_G^2 - \rho - f_1 t} \right)}{t \left( \hat{z} - \rho + \lambda_G^2 \right)},
\]

and

\[
f_1 = \sqrt{\hat{z}^2 + \left( \lambda_G^2 - \rho \right)^2} - 2 \hat{z} \left( \lambda_G^2 + \rho \right), \\
f_2 = \hat{z}^2 + 2 E_0^2 \left( 1 + t^2 \right) \lambda_G^2 + \left( \lambda_G^2 - \rho \right)^2 - 2 \hat{z} \rho. (8)
\]

The IR singularities present in the unintegrated spectra are regulated by a gluon mass \( \lambda_G \) in this calculation and the divergence cancels between the virtual and bremsstrahlung graphs once one integrates over phase space. The divergence directly cancels in integrations of these structure functions as the first two bremsstrahlung terms in \( W_{1c}^1 \) each contribute a factor of \( 8 \log (\lambda_G) \), while the final term contributes a factor of \( 8/t \log \left( \frac{1 + t}{1 - t} \right) \log (\lambda_G) \). For the purposes of this paper it is sufficient to numerically integrate the \( \mathcal{O}(\alpha_s) \) spectrum with the regulator assigned a small numerical value \( \lambda_G \sim 10^{-6} \). The \( \text{Li}_2 (\hat{z}) \) functions in \( W_{1}^1 \) are the Dilogarithm functions, defined as \( \text{Li}_2 (\hat{z}) \equiv \sum_{k=1}^{\infty} \frac{\hat{z}^k}{k^2} \) or equivalently, as \( \text{Li}_2 (\hat{z}) \equiv \int_{0}^{\hat{z}} \frac{\log(1-t)}{t} dt \). The other structure functions vanish at tree level in the limit \( m_c \rightarrow 0 \) and are IR safe at \( \mathcal{O}(\alpha_s) \). For these structure functions we find,
\( W_2'(y, \hat z) = W_{2a}(E_0, t, \hat z) \delta(\hat z - \rho) + W_{2b}(E_0, t, \hat z) \theta(\hat z - \rho), \)

\( W_{2a}(E_0, t, \hat z) = -\frac{2(\hat z + \rho)}{E_0 t} \log \left( \frac{1 + t}{1 - t} \right), \)  

\( W_{2b}(E_0, t, \hat z) = \frac{\hat z}{E_0 t^4} - \frac{4(\hat z + \rho)}{E_0^2 t^4} - \frac{(\hat z^2 + 8\hat z - \rho^2)}{E_0^3 t^4} + \frac{4 \hat z (\hat z + \rho)}{E_0^4 t^4} \) 
\[ + \left( -\frac{4}{E_0} + \frac{2(\hat z + \rho)}{E_0^2} - \frac{(\hat z^2 - 8\hat z - \rho^2)}{2E_0^3} - \frac{2 \hat z (\hat z + \rho)}{E_0^4} + \frac{\hat z (\hat z^2 - \rho^2)}{2E_0^5} \right) \frac{1}{t^5} \log \left( \frac{1 + t}{1 - t} \right) \)

\( W_3'(y, \hat z) = W_{3a}(E_0, t, \hat y) \delta(\hat z - \rho) + W_{3b}(E_0, t, \hat z) \theta(\hat z - \rho) \)

\( W_{3a}(E_0, t, \hat y) = \frac{\hat z}{y} \left( -\frac{2(1 + \hat y - \rho)}{E_0 t} \log \left( \frac{1 + t}{1 - t} \right) - 4 \log(\rho) \right) \)

\( W_{3b}(E_0, t, \hat z) = \frac{16}{E_0 t^4} - \frac{14(\hat z - \rho)}{E_0^2 t^4} + \frac{3(\hat z - \rho)^2 - 16\hat z}{E_0^3 t^4} - 4 \hat z \frac{(\hat z - \rho)}{E_0^4 t^4} \)
\[ + \left( -\frac{8}{E_0} + \frac{4(\hat z - \rho)}{E_0^2} - \frac{(\hat z - \rho)^2 - 8\hat z}{E_0^3} + \frac{5 \hat z (\hat z - \rho)}{E_0^4} - \frac{\hat z (\hat z - \rho)^2}{2E_0^5} \right) \frac{1}{t^5} \log \left( \frac{1 + t}{1 - t} \right) \)

\( W_4'(y, \hat z) = W_{4a}(E_0, t, \hat z) \theta(\hat z - \rho) \)
\[ W_{4a}(E_0, t, \hat z) = \frac{2(\hat z - \rho)}{\hat z E_0 t^4} - \frac{(\hat z - \rho)^2}{\hat z E_0^2 t^4} + \frac{16(\hat z - \rho)}{E_0^3 t^4} - \frac{2(\hat z - \rho)^2}{E_0^4 t^4} \]
\[ + \left( -\frac{7(\hat z - \rho)}{E_0^3} + \frac{3(\hat z - \rho)^2}{2E_0^4} - \frac{2 \hat z (\hat z - \rho)}{E_0^5} \right) \frac{1}{t^5} \log \left( \frac{1 + t}{1 - t} \right) \)

\( W_5'(y, \hat z) = W_{5a}(E_0, t, \hat y) \delta(\hat z - \rho) + W_{5b}(E_0, t, \hat z) \theta(\hat z - \rho) \)

\( W_{5a}(E_0, t, \hat y) = \frac{1}{y} \left( \frac{2(1 - \hat y - \rho)}{E_0 t} \log \left( \frac{1 + t}{1 - t} \right) + 4 \log(\rho) \right) \)

\( W_{5b}(E_0, t, \hat z) = \frac{2(\hat z^2 - \rho^2)}{E_0 \hat z E_0^2 t^4} + \frac{2(11\hat z - 3\rho)}{E_0^3 t^4} + \frac{(\hat z - \rho)^2 - 4 \rho (\hat z - \rho)}{E_0^4 t^4} + \frac{4(\hat z + 3\rho)}{E_0^4 t^4} \)
\[ + \left( \frac{8}{E_0^2} - \frac{2(\hat z - \rho)}{E_0^3} + \frac{\hat z - 9 \rho}{E_0^4} + \frac{\hat z^2 + 2 \hat z \rho - 3 \rho^2}{2E_0^5} \right) \frac{1}{t^5} \log \left( \frac{1 + t}{1 - t} \right). \)

We have checked the hadron tensor at \( \mathcal{O}(\alpha_s) \) by integrating our results to compare against known \( \mathcal{O}(\alpha_s) \) spectra and agree with [26] and the historical [30], but disagree, as do these other authors, with [27]. We also agree with the total \( \mathcal{O}(\alpha_s) \) contribution to the decay rate in [31]. The massless limit of the \( \mathcal{O}(\alpha_s) \) hadron structure functions has been taken for all regular terms and we find we agree with the regular terms for a massless final state [26].
C. Lepton Tensor and Phase Space

To find moments of the triple differential spectrum one must integrate over phase space while imposing the experimentally required cut on the lepton energy. With no lepton energy cut the phase space is given by the following region \[26\], referred to as region \(R_I\),

\[
\frac{1}{2}(b - \sqrt{b^2 - \hat{y}}) \leq \hat{E}_\ell \leq \frac{1}{2}(b + \sqrt{b^2 - \hat{y}}),
\]

\[
(\sqrt{\rho} + \lambda_G)^2 \leq \hat{z} \leq (1 - \sqrt{\hat{y}})^2,
\]

\[
0 \leq \hat{y} \leq (1 - \sqrt{\rho} - \lambda G)^2.
\]

where \(b \equiv 1/2 (1 - \hat{z} + \hat{y})\) and \(\rho = m_c^2/m_b^2\). Without a lepton energy cut in the phase space, the lepton tensor integrated over the lepton energy \(\hat{E}_\ell\) is

\[
L_{\mu\nu}(\hat{y}, \hat{z}) = \hat{y}/3 (-g_{\mu\nu} + \hat{q}_\mu \hat{q}_\nu/\hat{y}).
\]  

When a minimum cut \(E_{\ell}^{\text{min}} \geq x m_b\) is introduced, the phase space and the lepton tensor are modified. We do not repeat the derivation of the lepton tensor with a cut here, see \[32\], but note that the phase space splits into three regions when a cut is imposed. These three regions correspond to the partitioning of phase space that occurs when the electron energy lies below or within the phase space integration range as shown in Fig. 2. We only consider cuts below the upper limit of \(E_\ell\) as given in Eq. \[13\], this corresponds to only considering cuts where \(E_{\ell}^{\text{min}} \leq m_b(1 - \sqrt{\rho})/2\).

For \(x \leq 1/2 \left( a - \sqrt{a^2 - \hat{y}} \right)\), where \(a \equiv 1/2 \left( 1 - (\sqrt{\rho} + \lambda_G)^2 + \hat{y} \right)\) the cut, labelled as \(x_1\) in Fig. 2, is below the lower limit of the lepton energy in Eq. \[13\] and as the integration over the lepton energy is unaffected, the lepton tensor with this cut reduces to the simple expression above with the electron energy integrated over

\[
\frac{1}{2}(b - \sqrt{b^2 - \hat{y}}) \leq \hat{E}_\ell \leq \frac{1}{2}(b + \sqrt{b^2 - \hat{y}}).
\]

However, this lepton energy cut still affects the subsequent integrations of \(\hat{z}\) and \(\hat{y}\) by imposing the constraint on the range of \(\hat{y}\),

\[
(1 - (\sqrt{\rho} + \lambda G)^2 - 2x) \frac{2x}{1 - 2x} \leq \hat{y}, \tag{16}
\]
so that the remaining kinematic variables are integrated over the phase space region $R_{II}$,

$$\left(\sqrt{\rho} + \lambda G\right)^2 \leq \hat{z} \leq \left(1 - \sqrt{\hat{y}}\right)^2 \tag{17}$$

$$\left(1 - \left(\sqrt{\rho} + \lambda G\right)^2 - 2x\right) \frac{2x}{1 - 2x} \leq \hat{y} \leq \left(1 - \sqrt{\rho} - \lambda G\right)^2 \tag{18}$$

For $x \geq 1/2 \left(a - \sqrt{a^2 - \hat{y}}\right)$ while $x \leq \sqrt{\hat{y}}/2$, labelled in the diagram as the cut $x_2$, the phase space splits into two regions. The first region $R_{III}$ has the hadron tensor contracted with the lepton tensor of Eq. (14), and the range of $\hat{E}_t$ as given by Eq. (15). The remaining phase space variables are then integrated over the range,

$$\left(1 - 2x\right) \left(1 - \frac{\hat{y}}{2x}\right) \leq \hat{z} \leq \left(1 - \sqrt{\hat{y}}\right)^2 \tag{18}$$

$$\left(2x\right)^2 \leq \hat{y} \leq \left(1 - \left(\sqrt{\rho} + \lambda G\right)^2 - 2x\right) \frac{2x}{1 - 2x}.$$

The second region of type $R_{III}$ combines with the region of phase space where $x \geq 1/2 \left(a - \sqrt{a^2 - \hat{y}}\right)$ while $x \geq \sqrt{\hat{y}}/2$, labelled as $x_3$ on Fig. 2. The resulting combined phase space has the lepton tensor incorporating the cut within the phase space range and the subsequent integration is given by the region $R_{IV}$,

$$x \leq \hat{E}_t \leq \frac{1}{2} \left(b + \sqrt{b^2 - \hat{y}}\right),$$

$$\left(\sqrt{\rho} + \lambda G\right)^2 \leq \hat{z} \leq \left(1 - 2x\right) \left(1 - \frac{\hat{y}}{2x}\right), \tag{19}$$

$$0 \leq \hat{y} \leq \left(1 - \left(\sqrt{\rho} + \lambda G\right)^2 - 2x\right) \frac{2x}{1 - 2x}.$$
III. HADRONIC MASS MOMENTS

A. 1S Mass Scheme

In calculating moments of the hadronic invariant mass spectrum, we use the 1S mass and the upsilon expansion \[22, 23\]. It is well known the pole mass renormalon \[24, 25\] ambiguity leads to unnecessarily badly behaved perturbation series for moments when a poor mass scheme is chosen. In the 1S scheme the renormalon ambiguity is of $O(\Lambda_{QCD}^4/m_b^4)$ and so we expect the perturbation series of moments of the spectra to be better behaved. We express moments in terms of the 1S mass, which is related to the $b$ quark pole mass through the relation \[22, 23\]

$$\frac{m_b^{1S}}{m_b^{pole}} = 1 - \frac{(\alpha_s C_F)^2}{8} \left\{ 1 + \frac{\alpha_s}{\pi} \left[ \left( \ell + \frac{11}{6} \right) \beta_0 - 4 \right] \epsilon^2 + O(\epsilon^3) \right\}, \quad (20)$$

where $\ell = \log[\mu/(m_b\alpha_s C_F)]$ and $C_F = 4/3$. The parameter $\epsilon = 1$ determines the order in the modified perturbative expansion. Using the upsilon expansion necessitates introducing a modified perturbative expansion in order to ensure the cancellation of renormalon ambiguities \[22\]. When calculating in the 1S mass scheme the $O(\alpha_s^n)$ perturbative corrections coming from the mass transformation Eq. (20) are counted using the parameter $\epsilon^{n-1}$, while $O(\alpha_s^n)$ corrections in the decay rate are counted as $\epsilon^n$.

The dependence on the pole mass of the charm quark in our results is eliminated through,

$$m_b^{pole} - m_c^{pole} = \bar{m}_B - \bar{m}_D + \lambda_1 \left( \frac{2\bar{m}_D - m^*}{2\bar{m}_D \bar{m}_D} \right) + \lambda_1 \frac{m^* - 2\bar{m}_B}{4\bar{m}_D^2} + \lambda_1 \Lambda_{1S} \frac{4\bar{m}_D^2 - m^*_X}{2m^*_D m^*_X}$$

$$- (\tau_1 + \tau_3 - \rho_1) \frac{m^*_D - 4\bar{m}_D^2}{4\bar{m}_D^2 m^*_X} + O(\Lambda_{QCD}^4/m_b m^*_c). \quad (21)$$

The meson masses $\bar{m}_D$ and $\bar{m}_B$ are the spin averaged meson masses $\bar{m}_X = (m_X + 3m_X')/4$. In this relation we use the fact that $\frac{m_X}{2} - m_b^{1S} \sim \Lambda_{QCD}$ and expand in the parameter $\Lambda_{1S}$

$$\Lambda_{1S} \equiv \frac{m^*_X}{2} - m_b^{1S}. \quad (22)$$

The perturbative corrections coming from expressing the $b$ quark mass in terms of the 1S mass are determined by using the definitions of $\Lambda_{1S}$ and $m_b^{1S}$ and the HQET relationship between meson masses and quark masses

$$m_H = m_Q + \bar{A} - \frac{\lambda_1 + d_H \lambda_2}{2m_Q} + \frac{\rho_1 + d_H \rho_2}{4m_Q^2} - \frac{\tau_1 + \tau_3 + d_H (\tau_2 + \tau_4)}{4m_Q^2} + O(\frac{\Lambda_{QCD}^4}{m_Q^4}). \quad (23)$$
where $m_H$ is the hadronic mass, $m_Q$ is the heavy quark mass, and $d_H = 3$ for the pseudoscalar mesons while $d_H = -1$ for the vector mesons.

In calculating the general hadronic moment, previously calculated moments by Bauer, Ligeti, Luke, and Manohar (BLLM) \[17\] were reexamined in the 1S mass scheme to check results. The results presented in the following sections for the first hadronic moment and its variance are different for two reasons. First, in BLLM a $1/m_B$ expansion was used to replace $m_B$ in the expansion of $s_H$ in terms of partonic variables,

$$m_B = \bar{m}_B + \frac{3}{4} \left( m_\tau - 4 \bar{m}_B \right) \frac{\lambda_2}{\bar{m}_B^2} - \frac{3 \lambda_2 \Lambda_{1S}}{2 \bar{m}_B^2} - \frac{3}{4 \bar{m}_B^2} (\tau_2 + \tau_4) + \frac{3}{4 \bar{m}_B^2} \rho_2 + \mathcal{O} \left( \frac{\Lambda_{QCD}^4}{m_B^3} \right) \quad (24)$$

In the results reported in the following sections we always use a $1/m_\tau$ expansion. The corresponding expansion is

$$m_B = \bar{m}_B - \frac{3 \lambda_2}{m_\tau} - \frac{6 \lambda_2 \Lambda_{1S}}{m_\tau^2} - \frac{3}{m_\tau^2} (\tau_2 + \tau_4) + \frac{3}{m_\tau^2} \rho_2 + \mathcal{O} \left( \frac{\Lambda_{QCD}^4}{m_\tau^3} \right). \quad (25)$$

Second, we treat a class of powers of $(\bar{m}_B - m_\tau^2)^n$ differently than BLLM. When terms are generated by changing $\bar{\Lambda} \equiv m_B - m_b$ into $\Lambda_{1S}$,

$$\bar{\Lambda} = \left( \bar{m}_B - \frac{m_\tau^2}{2} \right) + \Lambda_{1S} + \frac{\lambda_1}{m_\tau} + \frac{2 \Lambda_{1S} \lambda_1}{m_\tau^2} + \frac{(\tau_1 + \tau_3 - \rho_1)}{m_\tau^2} + \mathcal{O} \left( \frac{\Lambda_{QCD}^4}{m_\tau^3} \right), \quad (26)$$

the $(\bar{m}_B - m_\tau^2)^n$ terms are kept only for $n \leq 3$. In BLLM this class of terms are treated as $\mathcal{O}(1)$ although they are formally of order $\Lambda_{QCD}^n$, leading to this class of higher order terms of $(\bar{m}_B - m_\tau^2)^n$ being kept and summed into the coefficients of the nonperturbative parameters. In the following results, the $(\bar{m}_B - m_\tau^2)^n$ terms from $\bar{\Lambda}$ are counted as order $\Lambda_{QCD}^n$ and in the results of Section [11] they are kept only up to $\mathcal{O}(\Lambda_{QCD}^3)$ in the nonperturbative expansion and up to $\mathcal{O}(\Lambda_{QCD})$ for perturbative terms. Factors of $(\bar{m}_B - m_\tau^2)$ are also generated in the replacement of the $c$ and $b$ quark mass and these factors are treated as $\mathcal{O}(1)$. This implementation of the 1S scheme is similar to the the general moment analysis of the lepton energy spectrum \[20\]. The lepton moments are presented in Appendix C and can be combined with the hadronic spectrum results to cross check extractions of $\Lambda_{1S}$ and $\lambda_1$ from these differing spectra. Further hadronic moments that are appropriate for a global fit, such as $s_H^{1/2}$ and $s_H^{3/2}$ are presented in Appendix B.
B. Decay Width to $\mathcal{O}(\alpha_s \Lambda_{\text{QCD}}/m_b), \mathcal{O}(\Lambda_{\text{QCD}}^3/m_b^3)$

With the 1S scheme implemented as discussed in the previous section, the decay width of $B \rightarrow X_c \ell \bar{\nu}$ is

$$\Gamma (B \rightarrow X_c \ell \bar{\nu}) = \Gamma_0 \left(0.5325 - 1.132 \frac{\Lambda_{1S}}{m_T/2} - 0.924 \left(\frac{\Lambda_{1S}}{m_T/2}\right)^2 - 1.89 \left(\frac{\Lambda_{1S}}{m_T/2}\right)^3\right)$$

$$- 2.12 \frac{\lambda_1}{(m_T/2)^2} - 3.93 \frac{\lambda_2}{(m_T/2)^2} + 0.74 \frac{\lambda_1 \Lambda_{1S}}{(m_T/2)^3} - 1.73 \frac{\lambda_2 \Lambda_{1S}}{(m_T/2)^3}$$

$$- 5.99 \frac{\rho_1}{(m_T/2)^3} + 4.94 \frac{\rho_2}{(m_T/2)^3} - 2.98 \frac{\tau_1}{(m_T/2)^3} + 0.99 \frac{\tau_2}{(m_T/2)^3}$$

$$- 4.96 \frac{\tau_3}{(m_T/2)^3} - 4.94 \frac{\tau_4}{(m_T/2)^3} - 0.080 \epsilon + 0.133 \epsilon \frac{\Lambda_{1S}}{m_T/2}$$

$$+ 0.004 \epsilon \left(\frac{\Lambda_{1S}}{m_T/2}\right)^2,$$

where $\Gamma_0 = \frac{G_F^2 |V_{cb}|^2}{192 \pi^3} \left(\frac{m_T}{2}\right)^5$. Uncertainties in the values of $\Lambda_{1S}$, $\lambda_i$, $\rho_i$ and $\tau_i$ introduce uncertainties in the inclusive extractions of $|V_{cb}|$ using the decay width. In the nonperturbative expansion the largest theoretical uncertainty in the extraction of $|V_{cb}|$ comes from $\Lambda_{1S}$ and $\lambda_1$ which one can see introduce $\sim 2\%$ uncertainties, followed by the higher order nonperturbative terms which impose an uncertainty of $\sim 1\%$ as one can see by examining the results for the total decay width and estimating the size of the unknown terms with dimensional analysis.

The size of the $\mathcal{O}(\alpha_s^2)$ can be estimated by calculating the $\alpha_s^2 \beta_0$ contribution to $\mathcal{O}(\alpha_s^2)$ [17, 33, 34], although these terms are not included in this paper. This has been done in the 1S scheme for a number of observables and the full size of these corrections being treated as an error introduces $\sim 2\%$ uncertainty in the extraction of $|V_{cb}|$. The next largest uncalculated contributions in the decay width are the $\mathcal{O}(\alpha_s \lambda_i)$ and $\mathcal{O}(\alpha_s \Lambda_{1S})$ terms and the $\mathcal{O}(\Lambda_{\text{QCD}}^3/m_b^2 m_c^2)$ neglected terms. The size of the $\mathcal{O}(\alpha_s \Lambda_{\text{QCD}}^3/m_b^2 m_c^2)$ terms in the 1S scheme may be estimated by taking the size of the $\alpha_s \Lambda_{1S}$ and multiplying by $\Lambda_{\text{QCD}}/m_b \sim 0.1$. For the first moment, this indicates that the order of the $\alpha_s \lambda_i$ terms is expected to be $\sim 0.01 \Lambda_{\text{QCD}}^3$ which can be safely neglected in fits to determine the third order parameters in the OPE. However, completely uncorrelated uncertainties of this size for both $\alpha_s \lambda_i$ should be used to estimate the error on the fit. The size of the corrections introduced when using the mass splitting formula to replace the $c$ quark mass should also be estimated in a fit to extract the third order terms in the OPE, as well as uncertainties due to $1/m_b^4$ corrections to the
OPE. These number and size of these terms are completely unknown and the uncertainties introduced due to these terms can be estimated by introducing completely uncorrelated errors of their naive dimensional size.

C. Integral Hadronic Moments

The nonperturbative parameters in the decay width can be determined by global fits to moments calculated from the decay spectra of $B \to X_c \ell \bar{\nu}$ such as the hadronic invariant mass spectra. The first and second moments of the hadronic invariant mass spectrum have been known for some time \cite{8, 28}. The perturbative corrections to these moments were obtained by expressing the hadronic moments in terms of the known $O(\alpha_s)$ corrections to the lepton spectra and the leading order hadronic invariant mass spectra. This technique fails when a lepton energy cut is introduced into the phase space, and the general tensor results of Section II are required. In terms of partonic quantities the hadronic invariant mass is defined to be

$$s_H = (Q - q)^2 = m_B^2 - m_B m_b (1 - \hat{z} + \hat{y}) + m_b^2 \hat{y}. \quad (28)$$

It is conventional to examine the first hadronic moment once the spin averaged meson mass $\bar{m}_D^2$ is subtracted. Moments that give the mean and variance of the hadronic invariant mass spectrum with lepton energy cuts of differing values were re-examined recently by BLLM. These moments are defined with lepton energy cuts $E_{\ell}^{\text{min}}$,

$$S_1 \left(E_{\ell}^{\text{min}}\right) = \left<s_H - \bar{m}_D^2\right> |_{E_{\ell} \geq E_{\ell}^{\text{min}}}, \quad S_2 \left(E_{\ell}^{\text{min}}\right) = \left<(s_H - \langle s_H \rangle)^2\right> |_{E_{\ell} \geq E_{\ell}^{\text{min}}}. \quad (29)$$

These moments as functions of the cut on the lepton energy, including the previously uncalculated perturbative corrections are as follows. The coefficients stated are for the dimensionful nonperturbative parameters listed at the top of the column. The data used in the numerical evaluations in this paper are $\bar{m}_B = 5.3135$ GeV, $\bar{m}_D = 1.9730$ GeV, $m_{\Upsilon} = 9.4603$ GeV and the strong coupling is $\alpha_s(m_b) = 0.22$. For example for the first moment with no cut we find

$$S_1 (0) = 0.834 + 1.646 \Lambda_{1S} + 0.451 \Lambda_{1S}^2 + 0.16 \Lambda_{1S}^3 + 1.43 \lambda_1 - 0.34 \lambda_2 + 0.51 \lambda_1 \Lambda_{1S} + 0.07 \lambda_2 \Lambda_{1S} + 0.71 \rho_1 - 0.34 \rho_2 + 0.32 \tau_1 + 0.25 \tau_2 + 0.29 \tau_3 + 0.15 \tau_4 + 0.143 \epsilon + 0.175 \Lambda_{1S} \epsilon, \quad (30)$$
and in the following tables the leading order term of a moment $S_i$ is labelled $S_i^0$.

| $E_{\ell}^{\text{min}}$ | $S_i^0$ | $\Lambda_{1S}$ | $\Lambda_{1S}^2$ | $\Lambda_{1S}^3$ | $\lambda_1$ | $\lambda_2$ | $\lambda_1 \Lambda_{1S}$ | $\lambda_2 \Lambda_{1S}$ | $\rho_1$ | $\rho_2$ | $\tau_1$ | $\tau_2$ | $\tau_3$ | $\tau_4$ |

TABLE 2: Coefficients of the perturbative parameters for $S_1 (E_0)$.

For the $S_2 (E_0)$ moments, as explained in Section IIIA, the results differ from those stated in BLLM. This difference is formally of higher order, and in the nonperturbative expansion the overall effect of the differing implementations of the 1S scheme is small. The effect of these terms in the perturbative expansion is also small for most moments. However, the variance of the hadronic invariant mass spectrum is more sensitive to higher order terms due to the cancellation among leading order terms in the nonperturbative expansion. The 1S scheme as implemented in BLLM found that the variance increased as the lepton energy cut was increased due to the dominance of the $O (\alpha_s)$ term and the suppression of leading order nonperturbative corrections. The $O (\alpha_s)$ term is the dominant correction to the variance in the $m_b \to \infty$ limit. The experimentally measured lepton energy cut dependence has the variance decreasing as the lepton energy cut increases. When $(\bar{m}_B - \frac{m_B}{2})$ terms are treated as detailed in Section IIIA in the 1S scheme, the $O (\alpha_s)$ term and variance has the
experimentally measured dependence on the lepton energy cut, as can be seen in Table 3 and 4.

\end{array}
\]

TABLE 4: Coefficients of the perturbative parameters for \( S_2 (E_0) \).

The moments \( S_1 \) and \( S_2 \) with a lepton energy cut of 1.5 GeV have been experimentally measured by CLEO [12],

\[
S_1 (1.5 \text{ GeV}) = 0.251 \pm 0.066 \text{ GeV}^2, \quad (31)
\]

\[
S_2 (1.5 \text{ GeV}) = 0.576 \pm 0.170 \text{ GeV}^4, \quad (32)
\]

Using this data, we can extract values of \( \Lambda_{1S} \) and \( \lambda_1 \), for comparison with extractions from the unknown third order terms in the usual way using the results of recent fits when they substantially improve our knowledge of these terms beyond dimensional analysis. We use the HQET vector pseudoscalar mass splitting constraint to determine \( \lambda_2 = 0.12 \text{ GeV}^2 \) and the mass splitting formula to third order.
\[ \rho_2 - \tau_2 - \tau_4 = \frac{\kappa (m_c) \, m_b^2 \, m_c \, \Delta m_B - m_b \, m_c^2 \, \Delta m_D}{m_b - m_c \, \kappa (m_c)}, \quad (33) \]
to reduce the number of free parameters. A positive value of \( \rho_1 \) is imposed in accordance with vacuum saturation \([35]\) and is drawn from the range \([0, 0.125] \text{ GeV}^3\). The unknown matrix elements are then drawn from a flat distribution, the unknown third order terms are drawn from between \(\pm 0.125 \text{ GeV}^3\) while \(\lambda_1\) is drawn from \([-600, 0] \text{ MeV}^2\) in accordance with its full constrained range from the BLLM fit. We then extract the following values for \(\lambda_1\) and \(\Lambda_{1S}\):

\[ \Lambda_{1S} = [-0.13 \pm 0.05 \epsilon \pm 0.09 m_3] \text{ GeV} \]
\[ \lambda_1 = [-0.24 \pm 0.02 \epsilon \pm 0.09 m_3] \text{ GeV}^2. \quad (34) \]

The perturbative errors are estimated by using the two loop running of \(\alpha_s(\mu)\) to vary the scale of \(\alpha_s(\mu)\) between \(m_b/2 < \mu < 2m_b\). Adding the theoretical errors in quadrature we obtain \(m_b^{1S} = 4.86 \pm 0.10 \text{ GeV}\), which is in excellent agreement with the inclusive extraction using the lepton energy moments, \(m_b^{1S} = 4.84 \pm 0.10 \text{ GeV} \([20]\) and in agreement with the results of BLLM where \(m_b^{1S} = 4.74 \pm 0.10 \text{ GeV}\), despite the differences in the expansion and the larger number of observables in the fit. This extracted 1S mass \(m_b^{1S} = 4.86 \pm 0.10 \text{ GeV}\) translates into a value of the \(\overline{\text{MS}}\) mass \(\bar{m}_b(m_b) = 4.34 \pm 0.09 \text{ GeV}\) which can be compared with other extractions of the \(\overline{\text{MS}}\) mass found by examining moments of the \(b\bar{b}\) production cross section \([36, 37, 38, 39, 40]\), a recent analysis of which finds \(\bar{m}_b(m_b) = 4.25 \pm 0.08 \text{ GeV} \([41]\).

D. Fractional Moments

1. The \(1/m_c\) Expansion

In integer moments such as \(S_1\) and \(S_2\), a \(\Lambda_{\text{QCD}}/m_c\) expansion only enters the predicted value of a moment through the mass transformation relationship Eq. (21). Fractional moments have additional cuts in the complex \(q \cdot v\) plane due to the branch cut starting at \(s_H = 0\) when \(s_H\) is taken to a noninteger power. These branch cuts are separated from the physical cut by a scale set by \(m_c\), as the physical branch cut begins at \(s_H = m_D^2\). As \(m_c \to 0\) these cuts coalesce and one would expect predictions for fractional moments in this limit to
be ill defined, as discussed in recent work \[19\]. We find an explicit $m_b \Lambda_{QCD}/m_c^2$ expansion in calculations of fractional moments of $s_H$; the neglected terms in this expansion are numerically suppressed for hadronic invariant mass observables leading to a small numerical uncertainty being introduced. This can be shown by examining a general moment of the squared hadronic invariant mass $s_H^n$. The dependence of the general moment as a function of $n$ is found by performing an expansion of $s_H^n$:

$$s_H^n = \sum_{k=0}^{\infty} \sum_{l=0}^{k} \frac{\Gamma(n+1)}{\Gamma(n+1-k)\Gamma(k)} C^k_l \hat{z}^{n-k} m_b^{2n}.$$  \hspace{1cm} (35)

The coefficient functions $C^k_l$ are $O\left(\frac{\Lambda_{QCD}}{m_b^k}\right)$. Expanding up to $O\left(\frac{\Lambda_{QCD}^3}{m_b^3}\right)$ in the nonperturbative expansion we find,

$$s_H^n = \hat{z}^n m_b^{2n} \left[C^0_0 + \frac{n}{\hat{z}} (C^1_0 + \hat{y} C^1_1) + \frac{n(n-1)}{1! \hat{z}^2} \left(C^2_0 + \hat{y} C^2_1 + \hat{y}^2 C^2_2\right) + \frac{n(n-1)(n-2)}{2! \hat{z}^3} \left(C^3_0 + \hat{y} C^3_1 + \hat{y}^2 C^3_2 + \hat{y}^3 C^3_3\right)\right],$$  \hspace{1cm} (36)

where the $C^k_l$ are functions of $n$ and the nonperturbative matrix elements \footnote{These $C^k_l$ coefficient functions are reported in the Appendix.}. For integer moments this expression has no $1/\hat{z}$ dependence. However, for non-integer moments in this range one obtains contributions of order $\hat{z}^{-k}$ where $k \geq n$ is the ceiling of the fractional moment power $n$. As the lower limit of $\hat{z}$ is $\rho = m_c^2/m_b^2$, this corresponds to a $m_b \Lambda_{QCD}/m_c$ expansion entering into the calculations of fractional moments. This expansion does not seem to introduce a large uncertainty for fractional moments compared to integer moments as the neglected class of terms are numerically suppressed for $n$ values in the range $[0,3]$ but the best way to estimate the uncertainty introduced is under study. In the following investigation of hadronic fractional moments no additional uncertainty is added to account for this theoretical error and we examine how known sources of error primarily from unknown matrix elements can be reduced.

When examining a general moment $s_H^n$ to obtain interesting observables, we expand in the ratio $\Lambda_{QCD}/m_Q$ and then examine the $n$ and $E_{\ell}^{\min}$ dependence of the coefficient functions of the nonperturbative matrix elements. The essential observation motivating this approach is that one is allowed to choose $n$ and $E_{\ell}^{\min}$ within a range of reasonably accessible experimental
values, in order to maximize the utility of a measured moment in obtaining information on the nonperturbative matrix elements. We define a general moment function,

$$S[n, E_{\ell_1}, m, E_{\ell_2}] = \frac{\langle s^n \rangle_{E_1 \geq E_{\ell_1}}}{\langle s^m \rangle_{E_1 \geq E_{\ell_2}}}$$

so that

$$S_1\left(E_{\ell}^{\text{min}}\right) = S[1, E_{\ell}^{\text{min}}, 0, E_{\ell}^{\text{min}}] - \bar{m}_D^2,$$

$$S_2\left(E_{\ell}^{\text{min}}\right) = S[2, E_{\ell}^{\text{min}}, 0, E_{\ell}^{\text{min}}] - \left(S[1, E_{\ell}^{\text{min}}, 0, E_{\ell}^{\text{min}}]\right)^2.$$

Our search of the hadronic mass moments is restricted to the parameter space,

$$m < 3, \ n < 3, \ 0.5 \text{ GeV} < E_{\ell_i}^{\text{cut}} < 1.5 \text{ GeV},$$

(38)

to ensure a well behaved OPE. In this parameter space we find two types of moments of interest, moments that allow the OPE to be precisely tested for deviations from experiment and moments that allow one to extract the 1S mass with minimal error. We consider each type of moment in the following sections.

2. OPE Testing Moments

A discrepancy of the prediction of the OPE when compared with data can come from a number of possible sources when one is considering percent level extractions of $|V_{cb}|$: a higher order matrix element that is being neglected could be anomalously large, the OPE itself could not be converging or quark-hadron duality violation could effect determinations [42, 43, 44, 45, 46, 47]. By finding moments where only the leading order unknown nonperturbative parameters are suppressed and checking the predicted values against experiment, one can assess the theoretical error that is being assigned to the inclusive extraction of $|V_{cb}|$ in a clear and unambiguous fashion. This technique [20] has recently been used to test the OPE in the lepton energy spectrum. Measurements of these OPE testing observables in this spectrum indicated that the OPE is a valid description of the data to the percent level [48]. It is important to note that the OPE testing moments presented allow one to check that the error assigned in the extractions of $|V_{cb}|$ and $m_b$ is large enough to account for all of these possible effects if the OPE testing moments properly describe the data [49].
A selection of these OPE testing moments for the hadronic invariant mass spectrum is presented in Table 5. The nonperturbative parameters for these moments are not suppressed except for the leading unknown nonperturbative terms $\Lambda_{1S}$ and $\lambda_1$. A typical OPE testing moment is as follows,

$$D_a^1 = S[2, 0.5, 2.2, 0.7]$$

$$= 0.7779\left[1 + 0.168 \frac{\Lambda_{1S}}{m_T^2} + 0.345 \left( \frac{\Lambda_{1S}}{m_T^2} \right)^2 + 0.501 \left( \frac{\Lambda_{1S}}{m_T^2} \right)^3 + 0.01 \frac{\lambda_1}{(m_T/2)^2} \right.$$

$$- 1.05 \frac{\lambda_2}{(m_T/2)^2} - 1.94 \frac{\lambda_1 \Lambda_{1S}}{(m_T/2)^3} - 8.75 \frac{\lambda_2 \Lambda_{1S}}{(m_T/2)^3} + 6.18 \frac{\rho_1}{(m_T/2)^3}$$

$$- 0.25 \frac{\rho_2}{(m_T/2)^3} + 0.27 \frac{\tau_1}{(m_T/2)^3} + 3.71 \frac{\tau_2}{(m_T/2)^3} - 1.50 \frac{\tau_3}{(m_T/2)^3}$$

$$- 1.61 \frac{\tau_4}{(m_T/2)^3} - 0.0094 \epsilon - 0.008 \frac{\Lambda_{1S}}{m_T/2}] \quad (39)$$

Varying the unknown parameters in the same way, and treating the leading order nonperturbative parameters as unknowns and varying them over the region $\Lambda_{1S} = -0.13 \pm 0.1 \text{ GeV}$, $\lambda_1 = -0.3 \pm 0.3 \text{ GeV}^2$, this moment is predicted to be

$$D_a^1 = 0.7686 \pm 0.0018 \epsilon \pm 0.0040 \text{N.P.} \quad (40)$$

The perturbative error is obtained by the scale variation in the standard way. As in the lepton spectra, the OPE testing moments are such that with no nonperturbative input other than the known value of $\lambda_2$, we can predict the value of a moment to an accuracy of 1%.

As the error on the nonperturbative terms is reduced with global fits, it is important to cross check with the predicted and measured values of these moments in order to ensure the error on $|V_{cb}|$ and $m_{b}^{1S}$ is not being underestimated. Table 5 and 6 present a selection of OPE testing moments in the parameter space examined.

|   | $\Lambda_{1S}$ | $\Lambda_2^{1S}$ | $\Lambda_3^{1S}$ | $\lambda_1$ | $\lambda_2$ | $\lambda_1 \Lambda_{1S}$ | $\lambda_2 \Lambda_{1S}$ | $\rho_1$ | $\rho_2$ | $\tau_1$ | $\tau_2$ | $\tau_3$ | $\tau_4$ |

Note that moments of this type have a strong dependence on $\Lambda_{1S}$ and a weak dependence on $\lambda_1$ while the coefficients of the higher order terms in the nonperturbative series are not suppressed. These moments are thus well suited to measure the $b$ quark mass with minimal dependence on the unknown $\lambda_1$ nonperturbative parameter have also been found. Moments of this type are important as a measurement of $m_b^{1S}$ to this precision will be an important step in reducing the error on $|V_{ub}|$ as well as extracting $|V_{cb}|$. These moments are particularly suited to being used in a fit to extract the $1S$ mass. An example of this type of moment is

$$B_a^1 = S[3, 0.5, 0.5, 0.9]$$

$$= 51.9318 \left[1 + 3.215 \frac{\Lambda_{1S}}{m_T/2} + 2.609 \left( \frac{\Lambda_{1S}}{m_T/2} \right)^2 - 2.216 \left( \frac{\Lambda_{1S}}{m_T/2} \right)^3 + 0.40 \frac{\lambda_1}{(m_T/2)^2} \right]$$

$$+ 3.67 \frac{\lambda_2}{(m_T/2)^2} + 6.14 \frac{\lambda_1 \Lambda_{1S}}{(m_T/2)^3} + 45.49 \frac{\lambda_2 \Lambda_{1S}}{(m_T/2)^3} - 27.78 \frac{\rho_1}{(m_T/2)^3} + 4.10 \frac{\rho_2}{(m_T/2)^3}$$

$$- 0.004 \frac{\tau_1}{(m_T/2)^3} - 29.15 \frac{\tau_2}{(m_T/2)^4} + 13.26 \frac{\tau_3}{(m_T/2)^4} + 10.64 \frac{\tau_4}{(m_T/2)^5}$$

$$+ 0.084 \epsilon + 0.154 \epsilon \frac{\Lambda_{1S}}{m_T/2}] .$$

Note that moments of this type have a strong dependence on $\Lambda_{1S}$ and a weak dependence on $\lambda_1$ while the coefficients of the higher order terms in the nonperturbative series are not suppressed. These moments are thus well suited to measure the $b$ quark mass with minimal error on $|V_{ub}|$ as well as extracting $|V_{cb}|$. These moments are particularly suited to being used in a fit to extract the $1S$ mass. An example of this type of moment is

$$B_a^1 = S[3, 0.5, 0.5, 0.9]$$

$$= 51.9318 \left[1 + 3.215 \frac{\Lambda_{1S}}{m_T/2} + 2.609 \left( \frac{\Lambda_{1S}}{m_T/2} \right)^2 - 2.216 \left( \frac{\Lambda_{1S}}{m_T/2} \right)^3 + 0.40 \frac{\lambda_1}{(m_T/2)^2} \right]$$

$$+ 3.67 \frac{\lambda_2}{(m_T/2)^2} + 6.14 \frac{\lambda_1 \Lambda_{1S}}{(m_T/2)^3} + 45.49 \frac{\lambda_2 \Lambda_{1S}}{(m_T/2)^3} - 27.78 \frac{\rho_1}{(m_T/2)^3} + 4.10 \frac{\rho_2}{(m_T/2)^3}$$

$$- 0.004 \frac{\tau_1}{(m_T/2)^3} - 29.15 \frac{\tau_2}{(m_T/2)^4} + 13.26 \frac{\tau_3}{(m_T/2)^4} + 10.64 \frac{\tau_4}{(m_T/2)^5}$$

$$+ 0.084 \epsilon + 0.154 \epsilon \frac{\Lambda_{1S}}{m_T/2}] .$$

TABLE 6: Coefficients of the perturbative parameters for OPE testing moments and their predicted value.
error as the largest source of theoretical error is suppressed in a controlled fashion. Estimating the error on the extraction in the usual way one finds the $m_{1S}^{1S}$ mass extracted from this moment will have a theoretical error due to unknown matrix elements and perturbative terms of $\pm 50 \text{MeV (N.P.)} \pm 3 \text{MeV (}\epsilon\text{)}$, where the error is dominated by the unknown nonperturbative corrections at third order. Adding these errors in quadrature one obtains a theoretical error in the extraction $\sim 50 \text{MeV}$. It is important to experimentally measure moments of this type for a precise value of the $b$ quark mass to be extracted from this spectrum. This error assessment in the extraction of $m_{1S}^{1S}$ is assigned in accordance with how theoretical error is assigned in the OPE testing moments. By measuring both the OPE testing moments and the moments presented in this section, one can extract $m_{1S}^{1S}$ with an experimentally tested theoretical error; comparisons of the $b$ quark mass extracted in this way with extractions using other techniques will be a useful cross check of theoretical techniques.

A selection of moments of this type is given in Table 7 and 8.

TABLE 8: The perturbative parameters of moments to measure the 1S mass accurately, and the error estimated in using the moment to extract the 1S mass.
IV. CONCLUSIONS

We have presented the $O(\alpha_s)$ corrections to the structure functions of the hadronic tensor for $B \to X_c \ell \bar{\nu}$. The $O(\alpha_s)$ and $O(\alpha_s \Lambda_{\overline{QCD}}/m_b)$ perturbative corrections for lepton energy moments and hadronic invariant mass moments have been calculated. The effects of the charm quark expansion in fractional moments was shown to be small and moments that allow one to extract the nonperturbative parameters relevant for a percent level determination of $|V_{cb}|$ from inclusive $B$ decay were presented. Using the techniques outlined, a $b$ quark mass measurement with a theoretical error at the 50 MeV or better should be possible using the inclusive semileptonic decay data. This theoretical error assessment, including the assumption of negligible quark-hadron duality violation that this analysis relies upon, is directly testable with the OPE testing moments presented in this paper. Fits based on the results presented should allow an extraction of $|V_{cb}|$ with $\sim 2\%$ theoretical error. As the lepton energy cut dependence of the $O(\alpha_s \Lambda_{\overline{QCD}}/m_b)$ term is now known, the largest estimated theoretical uncertainty in inclusive extractions of $|V_{cb}|$ and $m_b^{1S}$ comes from the $O(\alpha_s^2)$ corrections.
ACKNOWLEDGMENTS

It is a pleasure to acknowledge Christian Bauer for collaboration in the early stages of this work, for pointing out the importance of the fractional moment charm quark issues and for comments on the manuscript. I am also grateful to Michael Luke, Craig Burrell and particularly Alex Williamson for helpful discussions and comments on the manuscript.

This work was supported in part by the Walter B. Sumner foundation.

APPENDIX A: $s_H$ EXPANSION

The coefficient functions of the general hadronic moment $s_H$ in terms of the pole mass and the HQET local operator expansion are as follows:

$$C_0^0 = 1 + \frac{n \Lambda}{m_b} - \frac{n (\lambda_1 + 3 \lambda_2 - (n - 1) \Lambda^2)}{2 m_b^2} + \frac{(n - 1) n \Lambda ((n - 2) \Lambda^2 - 3 (\lambda_1 + 3 \lambda_2))}{6 m_b^3}$$

$$- \frac{n (\tau_1 + 3 \tau_2 + \tau_3 + 3 \tau_4 - \rho_1 - 3 \rho_2)}{4 m_b^3}$$

$$C_0^1 = \frac{\Lambda}{m_b} - \frac{(\lambda_1 + 3 \lambda_2 - 2 n \Lambda^2)}{2 m_b^2} + \frac{n \Lambda ((n - 1) \Lambda^2 - 2 (\lambda_1 + 3 \lambda_2))}{2 m_b^3}$$

$$- \frac{(\tau_1 + 3 \tau_2 + \tau_3 + 3 \tau_4 - \rho_1 - 3 \rho_2)}{4 m_b^3}$$

$$C_0^2 = \frac{\Lambda^2}{2 m_b^2} + \frac{\Lambda (n \Lambda^2 - \lambda_1 - 3 \lambda_2)}{2 m_b^3}$$

$$C_0^3 = \frac{\Lambda^3}{3 m_b^3}$$

$$C_1^1 = - \frac{\Lambda}{m_b} - \frac{2 (n - 1) \Lambda^2 + \lambda_1 + 3 \lambda_2}{m_b^2} - \frac{(n - 1) \Lambda ((n - 2) \Lambda^2 - 2 (\lambda_1 + 3 \lambda_2))}{2 m_b^3}$$

$$+ \frac{(\tau_1 + 3 \tau_2 + \tau_3 + 3 \tau_4 - \rho_1 - 3 \rho_2)}{4 m_b^3}$$

$$C_1^2 = - \frac{\Lambda^2}{m_b^2} - \frac{2 \Lambda ((n - 1) \Lambda^2 - \lambda_1 - 3 \lambda_2)}{m_b^3}$$

$$C_1^3 = - \frac{\Lambda^3}{m_b^3}$$

$$C_2^2 = \frac{\Lambda^2}{m_b^2} + \frac{\Lambda ((n - 2) \Lambda^2 - \lambda_1 - 3 \lambda_2)}{m_b^3}$$

$$C_2^3 = \frac{\Lambda^3}{m_b^3}$$

**APPENDIX C: LEPTON ENERGY MOMENTS FOR FIT**

Lepton energy moments appropriate for extracting \( \Lambda_{1S} \) and \( \lambda_1 \) from previous work in terms of the inverse upsilon mass expansion and \( \bar{\Lambda}_{1S} \equiv \frac{m_\Upsilon}{2} - m^S_0 \) definition of Eq. via \( \Lambda_{1S}^{\text{lepton}} = (\bar{m}_B - \frac{m_\Upsilon}{2}) + \Lambda_{1S} \) are as follows. The general moment is defined for the lepton
spectrum in an identical fashion to the general moment for the hadronic invariant mass spectrum.

\[ R[n, E_{\ell_1}, m, E_{\ell_2}] = \frac{\int_{E_{\ell_1}}^{E_{\ell_2}} E_{\ell} \frac{dE}{dE_{\ell}} dE_\ell}{\int_{E_{\ell_1}}^{E_{\ell_2}} E_{\ell} \frac{dE}{dE_{\ell}} dE_\ell}, \]
