Comparison of the Diagnostic Utility of 4D-DSA with Conventional 2D- and 3D-DSA in the Diagnosis of Cerebrovascular Abnormalities

C. Sandoval-Garcia, P. Yang, T. Schubert, S. Schafer, S. Hetzel, A. Ahmed, and C. Strother

ABSTRACT

BACKGROUND AND PURPOSE: 4D-DSA is a time-resolved technique that allows viewing of a contrast bolus at any time and from any desired viewing angle. Our hypothesis was that the information content in a 4D-DSA reconstruction was essentially equivalent to that in a combination of 2D acquisitions and a 3D-DSA reconstruction.

MATERIALS AND METHODS: Twenty-six consecutive patients who had both 2D- and 3D-DSA acquisitions were included in the study. The angiography report was used to obtain diagnoses and characteristics of abnormalities. Diagnoses included AVM/AVFs, aneurysms, stenosis, and healthy individuals. 4D-DSA reconstructions were independently reviewed by 3 experienced observers who had no part in the clinical care. Using an electronic evaluation form, these observers recorded their assessments based only on the 4D reconstructions. The clinical evaluations were then compared with the 4D evaluations for diagnosis and lesion characteristics.

RESULTS: Results showed both interrater and interclass agreements ($\kappa = 0.813$ and $0.858$). Comparing the 4D diagnosis with the clinical diagnosis for the 3 observers yielded $\kappa$ values of 0.906, 0.912, and 0.906. The $\kappa$ values for agreement among the 3 observers for the type of abnormality were 0.949, 0.845, and 0.895. There was complete agreement on the presence of an abnormality between the clinical and 4D-DSA in 23/26 cases. In 2 cases, there were conflicting opinions.

CONCLUSIONS: In this study, the information content of 4D-DSA reconstructions was largely equivalent to that of the combined 2D/3D studies. The availability of 4D-DSA should reduce the requirement for 2D-DSA acquisitions.

D SA is the criterion standard for the angiographic evaluation of cerebrovascular diseases. Current clinical use of DSA is based on a combination of multiple 2D projections and 3D-DSA volume reconstructions. 3D-DSA is not time-resolved. Often, several 2D acquisitions are necessary because of vascular overlap or due to the inability to visualize a particular attribute or structure due to rapid vascular filling. 4D-DSA is a reconstruction technique that provides time-resolved 3D reconstructions (ie, 4D-DSA).\(^1\) Initial studies indicated that the ability to view the contrast bolus at any time from any angle provided by 4D-DSA eliminates the problems inherent in the use of 2D- and 3D-DSA (eg, vascular overlap).\(^2,3\)

To our knowledge, no formal comparison has been made of the utility of 4D-DSA compared with conventional 2D or 3D images. The purpose of our pilot study was to assess the hypothesis that the information content of a 4D-DSA reconstruction was equivalent to that of the combination of 2D- and 3D-DSA. If this hypothesis is correct, then it should be possible to reduce the number of 2D-DSAs required in diagnostic and therapeutic procedures. This then would translate into a saving in radiation exposure, contrast medium, and procedural time.

MATERIALS AND METHODS

Under an institutionally approved protocol, we retrospectively evaluated 26 patients who had undergone diagnostic angiograms as part of their routine evaluations from August 2013 through March 2015. We wanted our cohort to consist of subjects with the most common conditions subjected to conventional angiography at our institutions and attempted to do this by selecting consecutive patients who fell into the diagnostic categories of healthy, aneurysm, AVM, or AVF and also had $\geq 1$ 3D-DSA reconstruction. Our subjects included 9 with aneurysms, 8 healthy individuals, 6 with...
AVMs/AVFs, and 3 with vascular stenosis/occlusions. The 3D-DSAs from these subjects were then retrospectively reconstructed as 4D-DSAs (at the time of data collection, 4D-DSA was not approved for clinical use and thus was not available real-time in the angiography suite).

The final operative/radiology report was used to obtain the diagnosis and measurements that were made with the 2D + 3D combination. Once cases were collected and properly de-identified per existing institutional review board guidelines at the University of Wisconsin - Madison, the rotational projections from each 3D acquisition were transferred to a research workstation running both the commercial software (syngo X Work-Plane VB21; Siemens, Erlangen, Germany) and the 4D-DSA prototype software. These were then reconstructed as 4D-DSA with the prototype software. These 4D-DSA volumes constituted the test images that were evaluated in the study.

The cases were maintained on a research workstation and were reviewed independently by 3 fellowship-trained neurointerventionalists (2 neuroradiologists and 1 neurosurgeon) who had not been involved in any aspect of the patient’s clinical care. No clinical information was provided to these reviewers, and the cases were presented in random order. As in a clinical environment, the evaluators had the opportunity to customize and use all the functional features of the 4D-DSA reconstructions in the workstation (ie, window, level, volume clipping, and so forth) to study each case and complete an evaluation form.

An electronic evaluation form was applied by using a “drill-down” methodology in which specific aspects of the vascular pathology (if any) were answered on the basis of the evaluator’s previous

| Table 1: Results of the 3 evaluators decisions regarding the presence of an abnormality on the 4D studies |
|-----------------------------------------------|
| 4D Method       | Evaluator 1 | Evaluator 2 | Evaluator 3 |
|-----------------|-------------|-------------|-------------|
| Definitely yes  | 17 (100)    | 15 (100)    | 18 (100)    |
| Probably yes    | 2 (50)      | 3 (100)     | 1 (0)       |
| Unsure          | 0 (NaN)     | 1 (0)       | 0 (NaN)     |
| Probably no     | 2 (100)     | 0 (NaN)     | 0 (NaN)     |
| Definitely no   | 5 (100)     | 7 (100)     | 7 (100)     |

Note:—NaN indicates not a number.

| Table 2: Results of the 3 evaluator’s decisions when results were consolidated into responses of yes, unsure, and no |
|---------------------------------------------------------------|
| 4D Method       | Evaluator 1 | Evaluator 2 | Evaluator 3 |
|-----------------|-------------|-------------|-------------|
| Yes             | 19 (95)     | 18 (100)    | 19 (95)     |
| Unsure          | 0 (NaN)     | 1 (0)       | 0 (NaN)     |
| No              | 7 (100)     | 7 (100)     | 7 (100)     |

Note:—NaN indicates not a number.
The likelihood of an abnormality was also treated as a numeric outcome, and interrater agreement was assessed with intraclass correlation coefficient (2,1) as described by Shrout and Fleiss.6,7 The evaluator responses for the likelihood of an abnormality were condensed to 2 categories, to assess agreement of the likelihood of an abnormality on 4D with the 2D + 3D criterion standard diagnosis of abnormality. "Definitely yes" and "probably yes" were considered "yes" for presence of abnormality, and "definitely no" and "probably no" were considered "No." The 1 response of "unsure" was treated as an incorrect assessment and was, therefore, defined as "yes" when the 2D + 3D diagnosis was "no" abnormality. Agreement in the abnormality diagnosis between 4D and 2D + 3D was assessed with the individual Cohen κ for each evaluator and for a consensus of the 3 evaluators. Sensitivity, specificity, positive/negative predictive values, and area under the ROC curve were assessed with intraclass correlation coefficient (2,1) for interrater reliability of ordinal categoric data was 0.882.

### RESULTS

To determine whether 4D images alone were sufficient to answer the 2 main diagnostic questions, whether there is an abnormality in the study and, if so, the type of abnormality and its characteristics, we analyzed the 26 datasets according to the methods just described.

### Is There an Abnormality in the Study? 

Tables 1 and 2 show the results for each evaluator. A correct 4D evaluation was defined as the evaluator’s response equal to “definitely yes” or “probably yes” when the results of the standard method were “definitely yes,” or the evaluator’s response being equal to “definitely no” or “probably no” when the results of the standard method were “definitely no.” The Fleiss κ for interrater agreement was 0.559, and the intraclass correlation coefficient (2,1) for interrater reliability of ordinal categoric data was 0.882. Consolidating the 4D responses to “yes” = “definitely yes” or “probably yes” and “no” = “definitely no” or “probably no” yielded a Fleiss κ for interrater agreement of 0.813. Intraclass correlation coefficient (2,1) for interrater reliability of ordinal categoric data was similar at 0.858.

After comparing interrater reliability, we then proceeded to analyze the agreement between the clinical diagnosis of 2D + 3D and measurement questions identical to those included in the clinical report. A sample of the questionnaire is shown in Fig 1.

Study data were collected and managed by using Research Electronic Data Capture (REDCap) electronic data capture tools (https://catalyst.harvard.edu/services/redcap/) hosted at the University of Wisconsin Institute for Clinical and Translational Research with grant support (Clinical and Translational Science Award program, through the National Institutes of Health National Center for Advancing Translational Sciences, grant UL1TR000427). REDCap® is a secure, Web-based application designed to support data capture for research studies, providing an intuitive interface for validated data entry, audit trails for tracking data manipulation, and export procedures for seamless data downloads to common statistical packages.

Diagnosis, diagnostic confidence (ie, abnormality present: “definitely not,” “probably not,” “unsure,” “probably yes,” and “definitely yes”), and the abnormality characteristics derived from the evaluation forms were compared within evaluators and with the clinical reports.

### Statistical Analysis

Statistical analysis included using the Fleiss κ for assessing interrater agreement for multiple evaluators for the likelihood of an abnormality (5 category scales and 3 category scales) and type of abnormality.5 The likelihood of an abnormality was also treated as a numeric outcome, and interrater agreement was assessed with intraclass correlation coefficient (2,1) as defined by Shrout and Fleiss.6,7 The evaluator responses for the likelihood of an abnormality were condensed to 2 categories, to assess agreement of the likelihood of an abnormality on 4D with the 2D + 3D criterion standard diagnosis of abnormality. "Definitely yes" and "probably yes" were considered "yes" for presence of abnormality, and "definitely no" and "probably no" were considered "No." The 1 response of "unsure" was treated as an incorrect assessment and was, therefore, defined as "yes" when the 2D + 3D diagnosis was "no" abnormality. Agreement in the abnormality diagnosis between 4D and 2D + 3D was assessed with the individual Cohen κ for each evaluator and for a consensus of the 3 evaluators. Sensitivity, specificity, positive/negative predictive values, and area under the ROC curve were assessed with intraclass correlation coefficient (2,1) for interrater reliability of ordinal categoric data was 0.882.

### RESULTS

To determine whether 4D images alone were sufficient to answer the 2 main diagnostic questions, whether there is an abnormality in the study and, if so, the type of abnormality and its characterization, we analyzed the 26 datasets according to the methods just described.

### Is There an Abnormality in the Study?

Tables 1 and 2 show the results for each evaluator. A correct 4D evaluation was defined as the evaluator’s response equal to “definitely yes” or “probably yes” when the results of the standard method were “definitely yes,” or the evaluator’s response being equal to “definitely no” or “probably no” when the results of the standard method were “definitely no.” The Fleiss κ for interrater agreement was 0.559, and the intraclass correlation coefficient (2,1) for interrater reliability of ordinal categoric data was 0.882. Consolidating the 4D responses to “yes” = “definitely yes” or “probably yes” and “no” = “definitely no” or “probably no” yielded a Fleiss κ for interrater agreement of 0.813. Intraclass correlation coefficient (2,1) for interrater reliability of ordinal categoric data was similar at 0.858.

After comparing interrater reliability, we then proceeded to analyze the agreement between the clinical diagnosis of 2D + 3D and measurement questions identical to those included in the clinical report. A sample of the questionnaire is shown in Fig 1.

Study data were collected and managed by using Research Electronic Data Capture (REDCap) electronic data capture tools (https://catalyst.harvard.edu/services/redcap/) hosted at the University of Wisconsin Institute for Clinical and Translational Research with grant support (Clinical and Translational Science Award program, through the National Institutes of Health National Center for Advancing Translational Sciences, grant UL1TR000427). REDCap® is a secure, Web-based application designed to support data capture for research studies, providing an intuitive interface for validated data entry, audit trails for tracking data manipulation, and export procedures for seamless data downloads to common statistical packages.

Diagnosis, diagnostic confidence (ie, abnormality present: “definitely not,” “probably not,” “unsure,” “probably yes,” and “definitely yes”), and the abnormality characteristics derived from the evaluation forms were compared within evaluators and with the clinical reports.
and the evaluators’ conclusions based on 4D. To assess this agreement, we assumed that categorizing the 4D image as “definitely yes” or “probably yes” matched a true diagnosis of “definitely yes” and that categorizing the 4D image as “definitely no” or “probably no” matched a true diagnosis of “definitely no.” A consensus among the 3 evaluators was defined as a classification on 4D imaging that was the same for at least 2 of the 3 evaluators.

Table 3 summarizes the data.

| 4D: True | Aneur | AVF | AVM | OD-S | None |
|---------|-------|-----|-----|------|------|
| Aneur   | 9     | 0   | 0   | 0    | 0    |
| AVF     | 0     | 3   | 0   | 0    | 0    |
| AVM     | 0     | 0   | 3   | 0    | 0    |
| OD-S    | 0     | 0   | 0   | 3    | 1    |
| None    | 0     | 0   | 0   | 0    | 7    |

Note: Aneur indicates aneurysm; OD-S, occlusive disease–stenosis.

Table 6: Summary of agreement between 4D and 2D/3D evaluations regarding type of abnormality (when there was one)*

| 4D:True | Aneur | AVF | AVM | OD-S | None |
|---------|-------|-----|-----|------|------|
| Aneur   | 9     | 0   | 0   | 0    | 0    |
| AVF     | 0     | 3   | 0   | 0    | 0    |
| AVM     | 0     | 0   | 3   | 0    | 0    |
| OD-S    | 0     | 0   | 0   | 7    | 0    |
| None    | 0     | 0   | 0   | 0    | 7    |

Note: Aneur indicates aneurysm; OD-S, occlusive disease–stenosis.

DISCUSSION

DSA remains the criterion standard for the evaluation of cerebrovascular pathology. Current practice usually involves the use of a com-
One of these is the potential for a reduction in the number of 2D acquisitions required for a particular study. While experience and in previous reports, the 4D studies have been particularly helpful in the assessment of the angioarchitecture of the nidus of AVMs and the location of the fistula connections in AVFs.

One motivation for the development of 4D-DSA was to provide a method that would allow a viewer to see an abnormality not just from any desired viewing angle but also at any time during the passage of a contrast bolus through the vasculature (Figs 2 and 3).

In our opinion, the availability of the 4D-DSA should further decrease the need for multiple 2D acquisitions. The benefit derived would be a reduction of patient and physician radiation exposure, contrast dose, and even the length of the procedure.

Limitations of our study include the small sample size and a lack of information regarding the prevalence of patients in whom it will be difficult or impossible to obtain a satisfactory rotational acquisition.

CONCLUSIONS

In this small study, the information obtained from 4D-DSAs alone was largely equivalent to that of the combined 2D- and 3D-DSA studies. Use of 4D-DSA should reduce the requirement for 2D-DSA acquisitions.
