Abstract. We present preliminary results from a systematic spectral study of pulsars and their wind nebulae using the Chandra X-Ray Observatory. The superb spatial resolution of Chandra allows us to differentiate the compact object’s spectrum from that of its surrounding nebulae. Specifically, for six Crab-like pulsars, we compare spectral fits of the averaged pulsar wind nebulae (PWN) emission to that of the central core using an absorbed power-law model. These results suggest an empirical relationship between the bulk averaged photon indices for the PWNe and the pulsar cores; \[ \Gamma_{PWN} = 0.8 \times \Gamma_{Core} + 0.8 \]. The photon indices of PWNe are found to fall in the range of \[ 1.3 < \Gamma_{PWN} < 2.3 \]. We propose that the morphological and spectral characteristics of the pulsars observed herein seem to indicate consistent emission mechanisms common to all young pulsars. We point out that the previous spectral results obtained for most X-ray pulsars are likely contaminated by PWN emission.

1. Introduction

Recent observation of pulsars associated with supernova remnants obtained with the Chandra X-ray observatory (Weisskopf, O’Dell & van Speybroeck 1996) are providing an unprecedentedly detailed view of pulsar wind nebulae. For the first time, emission features involving wisps, co-aligned toroidal structures, and axial jets are fully resolved in X-rays on arcsecond scales. These features, similar to those seen from the optical Crab nebula, are now found to be common to young, energetic pulsars in supernova remnants (Gotthelf 2001). Herein we present preliminary spectral analysis of several PWNe observed with Chandra, which, collectively, suggest a fundamental observational relationship between the spectral characteristics of pulsars and their pulsar wind nebulae.

Table 1 presents spectral results from a sample of Chandra pulsars which have characteristic wind nebulae. A summary of these objects along with references and images can be found in Gotthelf (2001). All observations were obtained with the ACIS-CCD camera which is sensitive to X-rays in the 0.2–10 keV band with an energy resolution of \[ \Delta E/E \sim 0.1 \] at 1 keV. The on-axis point spread function is slightly undersampled by the CCD pixels (0.5") allowing us to isolate the pulsar emission from that of the nebula. Except for N157B, which serendipitously fell on ACIS-I0, all data were obtained with ACIS-S3. The data were collected in nominal spectral (“FAINT”) and timing (3.24 s) mode and reduced and analyzed using the latest version of CIAO (CIAO 2.2/CALDB
Starting with the Level 1 processed event files we corrected the event data for CTI effects (Townsley et al. 2001) and applied the standard Level 2 filtering criteria, then further rejected time intervals of anomalous background rates.

| Remnant | $\Gamma_{\text{Averaged}}^{\text{PWN}}$ | $\Gamma_{\text{Core}}$ | $\Gamma_{\text{Pulsed}}^{\text{d}}$ | $\log L_{\nu, \text{NS}}$ | $\log L_{\nu, \text{PWN}}$ |
|---------|----------------------------------|----------------|----------------|----------------|----------------|
| G11.2−0.3 | 1.28±0.15 | 0.63±0.12 | 0.60±0.60 | 33.9 | 34.2 |
| Vela XYZ | 1.50±0.04 | 0.95±0.24 | 0.93±0.26 | 31.2 | 32.6 |
| Kes 75 | 1.88±0.04 | 1.13±0.11 | 1.10±0.30 | 35.2 | 36.0 |
| 3C 58 | 1.92±0.11 | 1.73±0.15 | ... | 33.0 | ... |
| Crab Nebula | 2.11±0.05 | 1.63±0.09 | 1.86±0.07 | 35.9 | 37.3 |
| N157B Nebula | 2.28±0.12 | 2.07±0.21 | 1.60±0.35 | 35.9 | 36.1 |

$^a$Ranked by increasing averaged PWN photon index.

$^b$Values for the following objects were taken from the literature: Crab: Willingale et al. (2001); N157B: Wang & Gotthelf 1998.

$^c$The value for the Crab pulsar has been obtained from the literature. The measured photon-indices have been corrected for pile-up as discussed in the text.

$^d$Pulsed PI value references: Vela: Strickman, Harding & Jager (1999); G11.2-0.3: Torii et al. (1997); Kes 75: Gotthelf et al. (2000); Crab: Pravdo, Angelini & Harding (1997); N157B: Marshall et al. (1998).

For each object listed in Table 1, we extracted spectra from the PWN, pulsar core, and background, when available, or obtained spectral parameters from the literature as indicated. For the core spectra, the brightest central pixels were extracted based upon data above 4.0 keV, where the core emission is substantially greater than that of the surrounding nebula. The nebula itself was then extracted from the region above which the background was constant, excluding the core. Large variations in background rates and size of both the nebula and the central source amongst observations precluded the use of a standard extraction aperture. Custom spectral response matrix functions (RMFs) were provided with the CTI correction software, and ancillary response functions (ARFs) were created according to standard CIAO 2.2 procedures, using the QEU calibration files similarly provided. All spectra were grouped to a minimum of 50 counts per spectral bin.

We fit the resultant background-subtracted pulsar and PWN spectra with a power-law model above 2 keV using the latest version of XSPEC (v11.1). The spectral fits to the core included a convolution model to account for pileup effects on the spectra. Table 1 lists the spectral parameters obtained for each object; the values for the Crab and N157B have been obtained from the literature (Willingale et al. (2001), Wang & Gotthelf 1998, respectively). No measurement of the pulsed spectrum for 3C58 is currently available. Absorption values were obtained by fitting the nebula spectra with an absorbed power-law above 0.6 keV, and were subsequently frozen for all future fits.
2. Results

The photon indices obtained from this analysis show a trend that the average PWN photon indices are consistently steeper than their core’s photon indices by a factor of one-half to one. We suggest that this relationship is linear, with the form $\Gamma_{PW} = 0.8 \times \Gamma_{Core} + 0.8$. This trend may be due to a number of factors. It may imply that the synchrotron spectrum frequency break occurs close to the neutron star, that there is a fundamental difference in emission
mechanisms between the two regions, or that the nebula is being powered by the core and that the steepening is due to synchrotron burnoff or a comparable aging mechanism.

*Chandra* is the first telescope able to spatially resolve the neutron star from the nebula. Previous spectral observation of pulsars are likely to be strongly contaminated by PWN emission. For example, we see no clear relationship between the power-law spectral index obtained for these pulsars by *ASCA* with any of those measured by *Chandra*. As more crab-like pulsars are observed and analyzed, a more complete picture of their morphological and spectral characteristics comes into view, paving the way for future models and simulations.
