THE NUMBER OF ATOMS IN AN ATOMIC DOMAIN

PETE L. CLARK, SAURABH GOSAVI, AND PAUL POLLACK

Abstract. We study the number of atoms and maximal ideals in an atomic domain with finitely many atoms and no prime elements. We show in particular that for all \(m, n \in \mathbb{Z}_+\) with \(n \geq 3\) and \(4 \leq m \leq \frac{3}{2}n^3\) there is an atomic domain with precisely \(n\) atoms, precisely \(m\) maximal ideals and no prime elements. The proofs involve an interplay of commutative algebra, algebraic number theory and additive number theory.

1. Introduction

1.1. Terminology. Let \(B \subset \mathbb{Z}_+\) be infinite, and let \(A \subset B\). We say the relative density of \(A\) in \(B\) is \(\delta\) if

\[
\lim_{n \to \infty} \frac{|A \cap [1, n]|}{|B \cap [1, n]|} = \delta.
\]

We say the density of \(A\) is \(\delta\) if the relative density of \(A\) in \(\mathbb{Z}_+\) is \(\delta\). Let \(R\) be a domain (a commutative ring without zero-divisors). Let \(R^* = R \setminus \{0\}\), \(R^*\) be the unit group and \(R^\circ = R^* \setminus R^\times\). An element \(p \in R^\circ\) is prime if the ideal \((p)\) is prime; \(p \in R^\circ\) is an atom if for all \(x, y \in R\), \(p = xy \implies x \in R^\times\) or \(y \in R^\times\). A domain \(R\) is atomic if every \(x \in R^\circ\) is a finite product of atoms and factorial if every \(x \in R^\circ\) is a finite product of primes. A domain is factorial if it is atomic and all atoms are prime [CA, Thm. 15.8]. A domain is primefree if it has no prime elements. For a domain \(R\) and a cardinal \(\kappa\), “\(R\) has \(\kappa\) atoms” means there is a set \(\mathcal{P}\) of atoms of \(R\) of cardinality \(\kappa\) such that every atom of \(R\) is associate to a unique \(p \in \mathcal{P}\). “\(R\) has \(\kappa\) maximal ideals” means the set MaxSpec \(R\) of maximal ideals of \(R\) has cardinality \(\kappa\).

A Cohen-Kaplansky domain is an atomic domain with \(\kappa < \aleph_0\) atoms. Let \(m, n \in \mathbb{Z}_+\) and let \(q\) be a prime power. A \(\text{CK}(n)\)-domain is an atomic domain with \(n\) atoms; a \(\text{CK}(n; q)\)-domain is a \(\text{CK}(n)\)-domain which is also an \(\mathbb{F}_q\)-algebra; and a \(\text{CK}(n; 0)\)-domain is a \(\text{CK}(n)\)-domain of characteristic 0. A \(\text{CK}(n, m)\)-domain is a \(\text{CK}(n)\)-domain with exactly \(m\) maximal ideals; a \(\text{CK}(n, m; q)\)-domain is a \(\text{CK}(n, m)\)-domain which is also an \(\mathbb{F}_q\)-algebra; and a \(\text{CK}(n, m; 0)\)-domain is a \(\text{CK}(n, m)\)-domain of characteristic 0.

1.2. Main Results. For a cardinal \(\kappa\) there is an atomic domain with \(\kappa\) atoms: if \(\kappa\) is finite we may take a localization of \(\mathbb{Z}\), and if \(\kappa\) is infinite we may take \(k[t]\) for a field \(k\) of cardinality \(\kappa\). These examples are not so interesting: they are factorial domains, so every atom is prime. Our point of departure in this note is the following:

Question 1. For which \(\kappa\) is there a primefree atomic domain with \(\kappa\) atoms?
In [CK46] Cohen-Kaplansky showed that a primefree atomic domain which is not a field has at least three atoms and that there are local primefree atomic domains with \( n \) atoms for \( 3 \leq n \leq 10 \) [CK46]. The case \( \kappa \geq \aleph_0 \) has already been handled.

**Theorem 1.1.** Let \( \kappa \) be an infinite cardinal. Then:

a) [Cl15, Thm. 5.2] There is a primefree local atomic domain with \( \kappa \) atoms.

b) [Cl15, Thm. 5.5] There is a primefree Dedekind domain with \( \kappa \) atoms.

We are left with the – more interesting! – case of \( \kappa < \aleph_0 \). Question 1 becomes: for which \( n \geq 3 \) is there a primefree \( CK(n) \)-domain? In this form it was raised by Coykendall-Spicer [CS12], who showed there are primefree \( CK(n) \)-domains for all \( n \geq 8 \) conditionally on the conjecture that every even \( n \geq 8 \) is a sum of two distinct primes. They derived this as a consequence of the following result.

**Theorem 1.2** (Coykendall-Spicer [CS12]). For any primes \( p_1 < \ldots < p_m \) there is a primefree \( CK(\sum_{j=1}^{m} (p_j + 1), m; 0) \)-domain.

In the 1930’s Chudakov, Estermann and van der Corput showed that the subset of even positive integers which are a sum of two primes has relative density 1 [Ch37, Ch38], [Es38], [vdC37]. From this and Theorem 1.2 it follows that the set of \( n \in \mathbb{Z}^+ \) for which there is a primefree \( CK(n, 2; 0) \)-domain or a primefree \( CK(n, 3; 0) \)-domain has density 1. We will give a stronger result with a similar proof, so we omit the details. By making a different – more elementary – analytic argument, we may deduce from Theorem 1.2 an answer to Question 1.

**Theorem 1.3.** For all \( n \geq 3 \) there is a primefree \( CK(n) \)-domain.

Here is the key idea of the proof: whereas Coykendall-Spicer apply Theorem 1.2 with \( m \in \{2, 3\} \), to get primefree \( CK(n, m) \)-domains, we may choose \( m \) in terms of \( n \). In fact it suffices to establish the following piece of additive number theory.

**Theorem 1.4.** For all \( n \geq 6 \) there are distinct prime numbers \( p_1, \ldots, p_m \) such that \( n = \sum_{j=1}^{m} (p_j + 1) \).

This maneuver leads us to ask a refined version of Question 1 in the finite case.

**Question 2.** For which \( m, n \in \mathbb{Z}^+ \) is there a primefree \( CK(n, m) \)-domain?

The main goal of this note is to address Question 2. We give a complete answer for \( m = 4 \), an answer up to finitely many \( n \) for \( m = 3 \), and an answer up to density 0 for \( m = 2 \). Moreover we conjecture a complete answer for all \( m \geq 2 \). For \( m = 1 \) we (only) record an implication of an old result of Cohen-Kaplansky. In more detail:

**Theorem 1.5.** If there is a primefree \( CK(n, m) \)-domain, then \( m \leq \frac{n}{3} \).

**Theorem 1.6.** Let \( m \) and \( n \) be positive integers.

a) If \( n \geq 10 \) is even and \( m \in [3, \frac{n}{7}] \), there is a primefree \( CK(n, m; 0) \)-domain.

b) If \( n \geq 13 \) is odd and \( m \in [4, \frac{n}{7}] \), there is a primefree \( CK(n, m; 0) \)-domain.

c) If \( n \) is sufficiently large, there is a primefree \( CK(n, 3; 0) \)-domain.

**Theorem 1.7.**

a) The set of \( n \in \mathbb{Z}^+ \) for which there is a primefree \( CK(n, 2; 0) \)-domain has density 1.
b) Conditionally on the Goldbach Conjecture – Conjecture 3.7 in §3 – for every even \( n \geq 6 \) there is a primefree \( \text{CK}(n, 2; 0) \)-domain.

c) Conditionally on Schinzel’s generalization of the Goldbach Conjecture – Conjecture 3.9 in §3 – for every sufficiently large odd integer \( n \) there is a primefree \( \text{CK}(n, 2; 0) \)-domain.

**Conjecture 1.8.** Let \( n \) be a positive integer.

a) There is a primefree \( \text{CK}(n, 2; 0) \)-domain iff \( n \geq 6 \).

b) There is a primefree \( \text{CK}(n, 3; 0) \)-domain iff \( n \geq 9 \).

**Theorem 1.9.** The set of primes \( n \) such that there is a primefree \( \text{CK}(n, 1) \)-domain has density \( 0 \) inside the set of all primes.

To prove these results we will draw from three different fields: commutative algebra, algebraic number theory and additive/analytic number theory. We will use the structure theory of Cohen-Kaplansky domains developed by Anderson-Mott [AM92] (commutative algebra) combined with an argument using Krasner’s Lemma to construct global fields with prescribed local behavior (algebraic number theory) to establish the following, our main algebraic result.

**Theorem 1.10 (Globalization Theorem).**

a) Let \( q \) be either 0 or a prime power. Let \( M, n_1, \ldots, n_M, m_1, \ldots, m_M \in \mathbb{Z}^+ \). Suppose for all \( 1 \leq j \leq M \) there is a primefree \( \text{CK}(n_j, m_j; q) \)-domain. Then there is a primefree \( \text{CK}(\sum_{j=1}^{M} n_j, \sum_{j=1}^{M} m_j; q) \)-domain.

b) If \( q_1, \ldots, q_m \) are prime powers and \( d_1, \ldots, d_m \geq 2 \) are integers, there is a primefree \( \text{CK}(\sum_{j=1}^{m} \frac{q_j^{d_j}-1}{q_j-1}, m; 0) \)-domain. If \( q_1, \ldots, q_m \) are all powers of a prime power \( q \), there is a primefree \( \text{CK}(\sum_{j=1}^{m} \frac{q_j^{d_j}-1}{q_j-1}, m; q) \)-domain.

The proofs of Theorems 1.6 and 1.7 combine the Globalization Theorem with results from additive number theory. These results lie considerably deeper than those used to prove Theorem 1.4 and include, notably, Helfgott’s recent affirmative solution of the ternary Goldbach problem [He15]. Fortunately for us they are easy to apply.

Finally, we apply Theorem 1.10 to give results in positive characteristic.

**Theorem 1.11.** Let \( q \) be a prime power.

a) If \( R \) is a primefree atomic domain which is an \( \mathbb{F}_q \)-algebra and not a field, then \( R \) has at least \( q + 1 \) atoms.

b) For all \( n \geq 3 \), there is a primefree \( \text{CK}(n; 2) \)-domain.

c) If \( q \) is even, then for all \( n \geq 2q^2 - q \) there is a primefree \( \text{CK}(n; q) \)-domain.

d) If \( q \) is odd, then for all \( n \geq 2q^2 - q + 1 \) there is a primefree \( \text{CK}(n; q) \)-domain.

1.3. **Structure of the Paper.** In §2 we give material on Cohen-Kaplansky domains. In §3 we will prove Theorems 1.3–1.7 and 1.9–1.11 and give supporting arguments for Conjecture 1.8. Final comments are given in §4.
2. Preliminaries on Cohen-Kaplansky Domains

There is a beautiful structure theory for Cohen-Kaplansky domains pioneered by Cohen-Kaplansky [CK46] and enhanced by Anderson-Mott [AM92]. In this section we recall some of these results – and quick consequences of them – for later use.

**Theorem 2.1** ([CK46]). A Cohen-Kaplansky domain is Noetherian and has only finitely many nonzero prime all ideals, all of which are maximal.

**Theorem 2.2.** Let $R$ be a semilocal domain, with maximal ideals $m_1, \ldots, m_m$.

a) $R$ is Cohen-Kaplansky iff $R_{m_j}$ is Cohen-Kaplansky for all $1 \leq j \leq m$.

b) Every atom $p$ of $R$ lies in $m_j$ for exactly one $j$, and $R \twoheadrightarrow R_{m_j}$ induces a bijection from the atoms of $R$ lying in $m_j$ to the atoms of $R_{m_j}$.

c) Suppose $R$ is Noetherian of dimension one. The following are equivalent:

(i) $R$ has a prime element.

(ii) For at least one $j$, $R_{m_j}$ has a prime element.

(iii) For at least one $j$, $R_{m_j}$ is a DVR.

**Proof.** Parts a) and b) are results from [CK46]. c) (i) $\implies$ (ii): if $p \in R$ is prime, then since $\dim R = 1$ we have $(p) = m_j$ for some $j$ and $p$ is a prime element of $R_j$. (ii) $\iff$ (iii): for all $j$, $R_{m_j}$ is one-dimensional local Noetherian, hence is a DVR iff the maximal ideal is principal [CA, Thm. 17.19]. (iii) $\implies$ (i): if $R_{m_j}$ is a DVR for some $j$, by part b) there is exactly one atom $p_j \in m_j$. Since $R$ is atomic and $m_j$ is prime, every element of $m_j$ is divisible by $p_j$, so $m_j = (p_j)$ and $p_j$ is prime. \(\square\)

**Lemma 2.3.** Let $(R, m)$ be a local atomic domain with residue field $k = R/m$.

a) Every element of $m \setminus m^2$ is an atom of $R$.

b) If two atoms $p, p' \in m \setminus m^2$ are associate, then $p \pmod{m^2}$ and $p' \pmod{m^2}$ generate the same one-dimensional $k$-subspace of $m/m^2$.

c) If $(R, m)$ is a primefree Cohen-Kaplansky domain then $k \cong \mathbb{F}_q$ is a finite field, $d = \dim_k m/m^2$ is finite, and $R$ has at least $\# \mathbb{F}^{d-1}(\mathbb{F}_q) = \frac{q^d-1}{q-1}$ atoms.

d) A primefree Cohen-Kaplansky domain has at least $3$ atoms.

**Proof.** Parts a) and b) are left to the reader. c) $R$ is a one-dimensional Noetherian local ring which is not a DVR, so $1 < \dim_k m/m^2 < \aleph_0$. By parts a) and b), choosing a nonzero element from each one-dimensional subspace of $m/m^2$ gives nonassociate atoms. This set is in bijection with the set of lines through the origin of the $\mathbb{F}_q$-vector space $m/m^2$, hence with $\mathbb{F}^{d-1}(\mathbb{F}_q)$. d) By Theorem 2.2 we reduce to the local case. Then, with notation as above we have at least $\# \mathbb{F}^{d-1}(\mathbb{F}_q) \geq \# \mathbb{F}^1(\mathbb{F}_q) = 3$ atoms. \(\square\)

**Theorem 2.4.**

a) [CK46, Thm. 13] For every prime power $q$ and $d \geq 2$, there is a primefree $\text{CK}(\frac{q^d-1}{q-1}, 1)$-domain.

b) [CK46, Cor., p. 475] If there is a primefree $\text{CK}(n, 1)$-domain for a prime number $n$, then $n$ is of the form $\frac{q^d-1}{q-1}$ for a prime power $q$ and an integer $d \geq 2$.

c) [AM92, Cor. 7.2] For any prime power $q$ and $d, e \in \mathbb{Z}^+$, $\mathbb{F}_q + t^e \mathbb{F}_q[[t]]$ is a $\text{CK}(e \frac{q^d-1}{q-1} q^{d(e-1)}, 1, q)$-domain. It is primefree unless $(d, e) = (1, 1)$.
Remark 2.5. As mentioned above, Theorem 2.4 implies there are primefree CK(n, 1)-domains for all 3 ⩽ n ⩽ 10 and there is not a primefree CK(11, 1)-domain.

We say a ring $R$ has finite residue fields if $R/m$ is finite for all $m ∈ \text{MaxSpec } R$. For a domain $R$ with fraction field $K$, and $I, J$ two $R$-submodules of $K$, we define

$$(I : J) = \{ x ∈ K \mid xJ ⊆ I \}.$$ 

Theorem 2.6. Let $(R, m)$ be a local Cohen-Kaplansky domain with residue field $k = R/m \cong \mathbb{F}_q$, and put $d = \dim_k m/m^2$. Let $\overline{R}$ be the normalization of $R$.

a) The ring $\overline{R}$ is a DVR, $\overline{R}$ is finitely generated as an $R$-module, and the ring $\overline{R}/(R : \overline{R})$ is finite. Let $\overline{m}$ be the maximal ideal of $\overline{R}$ and put $\overline{k} = \overline{R}/\overline{m} \cong \mathbb{F}_q$. Let $\tau : \overline{R} = \overline{k}$ be the quotient map.

b) The following are equivalent:

i) The ideal $m^2$ is universal: every element of $m^2$ is divisible by every atom of $R$.

ii) $R$ has $\frac{q_j - 1}{q_j - 1}$ atoms.

iii) We have $R = \tau^{-1}(\mathbb{F}_q)$.

iv) We have $\overline{m} = m = (R : \overline{R})$.

c) Under the equivalent conditions of part b), we have $d = D$.

Proof. a) The ring $\overline{R}$ is a DVR by the Krull-Akizuki Theorem. By [AM92, Thm. 2.4], $(R : \overline{R}) ⊃ (0)$. Thus $\overline{R}/\overline{m}$ is finitely generated as a module over $R/m \cong \mathbb{F}_q$, hence is a finite field, say $\overline{R}/\overline{m} \cong \mathbb{F}_q$. The conductor $(R : \overline{R})$ is the largest ideal of $R$ which is also an ideal of $\overline{R}$; since it is a nonzero ideal of a DVR with finite residue field, the ring $\overline{R}/(R : \overline{R})$ is finite. b) See [AM92, §5], c) Since $\overline{R}$ is a DVR, we have $1 = \dim_{\mathbb{F}_q} \overline{m}/\overline{m}^2$, so $[\overline{m} : m^2] = q^D$. But $m = \overline{m}$, so

$$[m : m^2] = [\overline{m} : m^2] = q^D$$

and

$$d = \dim_{R/m} m/m^2 = \dim_{\mathbb{F}_q} m/m^2 = \log_q [m : m^2] = D.$$

Let $R$ be a ring, let $I$ be an ideal of $R$, let $q : R → R/I$ be the quotient map, and let $S$ be a subring of $R/I$. Following Anderson-Mott [AM92], we call $q^{-1}(S)$ the composite of $R$ and $S$ over $I$. Thus the condition $R = \tau^{-1}(\mathbb{F}_q)$ in Theorem 2.6b) above is that $R$ is the composite of $\overline{R}$ and $\mathbb{F}_q$ over $\overline{m}$. On the other hand, Anderson-Mott characterize all Cohen-Kaplansky domains with finite residue fields (thus all primefree Cohen-Kaplansky domains) in terms of composites, as follows.

Theorem 2.7.

a) Let $D$ be a semilocal PID with finite residue fields and maximal ideals $\mathcal{M}_1, \ldots, \mathcal{M}_m$. Let $I = \mathcal{M}_1^{e_1} \cdots \mathcal{M}_m^{e_m}$ be an ideal of $D$, so $D/I \cong \prod_{j=1}^{m} D/\mathcal{M}_j^{e_j}$. For $1 ⩽ j ⩽ m$ let $S_j$ be a subring of $D/\mathcal{M}_j^{e_j}$, and put $S = \prod_{j=1}^{m} S_j \subset D/I$. Let $R$ be the composite of $D$ and $S$ over $I$. Then $R$ is a Cohen-Kaplansky domain with normalization $D$ and such that $(R : D) ⊃ I$. Moreover $R$ has precisely $m$ maximal ideals, namely $m_j = \mathcal{M}_j ∩ R$ for $1 ⩽ j ⩽ m$. 

b) Let $R$ be a Cohen-Kaplansky domain with finite residue fields, with normalization $\overline{R}$. Then $\overline{R}$ is a semilocal PID with maximal ideals $M_1, \ldots, M_m$, and each $\overline{R}/M_j$ is finite. The conductor ideal $(R : \overline{R})$ is nonzero, so may be written as $M_1^{e_1} \cdots M_m^{e_m}$, and the subring $S = R/(R : \overline{R})$ of $\overline{R}/(R : \overline{R}) \cong \prod_{j=1}^{m} \overline{R}/M_j^{e_j}$ may be decomposed as $\prod_{j=1}^{m} S_j$ with each $S_j$ a subring of $\overline{R}/M_j^{e_j}$. $R$ is the composite of $\overline{R}$ and $S$ over $(R : \overline{R})$.

Proof. This is a rewording of [AM92, Thm. 4.4] suitable for our purposes.

Remark 2.8. For a Cohen-Kaplansky domain $R$, its normalization $\overline{R}$ is a root extension: for all $r \in \overline{R}$ there is an $n \in \mathbb{Z}^+$ such that $r^n \in R$ [AM92, Lemma 4.1]. Thus $S = R/(R : \overline{R}) \subset \overline{R}/(R : \overline{R})$ is also a root extension. If $R = M_1^{e_1} \cdots M_m^{e_m}$ then by the Chinese Remainder Theorem $\overline{R}/(R : \overline{R})$ decomposes as a product of $m$ finite local rings, with corresponding idempotents $\epsilon_1, \ldots, \epsilon_m$. Since $\epsilon_j = \epsilon_j$ for all $n$, it follows that each $\epsilon_j$ lies in $S$. The $S_j$ in Theorem 2.7b) is the projection $S\epsilon_j$.

Corollary 2.9. Let $R$ be a Cohen-Kaplansky domain with finite residue fields which is the composite of $\overline{R}$ and $S = \prod_{j=1}^{m} S_j$ over $(R : \overline{R}) = M_1^{e_1} \cdots M_m^{e_m}$. Then:

a) $R$ has precisely $m$ maximal ideals, $m_j = M_j \cap R$.

b) The localization $R_m_j$ is the composite of $\overline{R}_{M_j}$ and $S_j$ over $(R_m_j : \overline{R}_{M_j}) = M_j^{e_j} \overline{R}_{M_j}$. The completion $\overline{R}_{m_j}$ is the composite of $\overline{R}_{M_j}$ and $S_j$ over $(\overline{R}_{m_j} : \overline{R}_{M_j}) = M_j^{e_j} \overline{R}_{M_j} = \overline{M_j}^{e_j}$.

c) For $1 \leq j \leq m$, let $R_j$ be the composite of $\overline{R}$ and $S_j$ over $M_j^{e_j}$. Then $R_j$ is a local Cohen-Kaplansky domain, $R = \bigcap_{j=1}^{m} R_j$ and $(R_j)_{M_j \cap R} = R_{M_j \cap R}$.

Proof. a) This is a property of Cohen-Kaplansky domains [AM92, Thm. 2.4].

b) Fix $1 \leq J \leq m$. By Theorems 2.2 and 2.7b), the ring $R_{m_j}$ is a local Cohen-Kaplansky domain and is the composite of $\overline{R}_{M_j} = \overline{R}_{m_j} = \overline{R} \otimes_R R_{m_j}$ and $R_{m_j}/(R_{m_j} : \overline{R}_{M_j}) = R_{m_j}/(R_{m_j} : \overline{R} \otimes R R_{m_j}) = R/(R : \overline{R}) \otimes_R R_{m_j} = \left( \prod_{j=1}^{m} S_j \right) \otimes_R R_{m_j}$

over $M_j^{e_j} \overline{R}_{M_j} = (R : \overline{R})R_{m_j} = (R_{m,j} : \overline{R}_{M_j})$. Consider the localization map

\[ \varphi : \prod_{j=1}^{m} S_j \to \left( \prod_{j=1}^{m} S_j \right) \otimes_R R_{m_j}, \]

which is the restriction of the localization map

\[ \overline{\varphi} : \prod_{j=1}^{m} \overline{R}/M_j^{e_j} \to \left( \prod_{j=1}^{m} \overline{R}/M_j^{e_j} \right) \otimes_R R_{m_j}. \]

Because

\[ \left( \prod_{j=1}^{m} \overline{R}/M_j^{e_j} \right) \otimes_R R_{m_j} = \prod_{j=1}^{m} \overline{R}_{M_j}/(M_j \overline{R}_{M_j})^{e_j} = \overline{R}_{M_j}/(M_j \overline{R}_{M_j})^{e_j} \]

\[ = \overline{R}_{M_j}/M_j^{e_j} \overline{R}_{M_j} \]

1Here we have used the canonical ring isomorphisms $\overline{R}/M_j^{e_j} \cong \overline{R}_{M_j}/M_j^{e_j} \overline{R}_{M_j} \cong \overline{R}_{M_j}/M_j^{e_j} \overline{R}_{M_j}$ to regard $S_j$ as a subring of the latter two rings.
we find that $\varphi$ factors through the projection $\prod_{j=1}^{m} \mathcal{R}/\mathcal{M}_j^{oj} \to \mathcal{R}/\mathcal{M}_j^{oj}$. Thus $\varphi$ factors through the projection $\prod_{j=1}^{m} S_j \to S_J$ to give an injection $\iota: S_J \to \left( \prod_{j=1}^{m} S_j \right) \otimes_R R_{m_j} = S_J \otimes_R R_{m_j}$.

Thus $\iota$ is an injective localization map on the local Artinian $R$-algebra $S_J$. Since every element of a local Artinian ring is either a nilpotent or a unit, any nonzero localization map on a local Artinian ring is an isomorphism, so $\iota$ identifies $S_J$ with $(\prod_{j=1}^{m} S_j) \otimes_R R_{m_j}$. The case of the completion is similar but easier.

c) The subring $\bigcap_{j=1}^{m} R_j$ is the set of elements $x \in \mathcal{R}$ such that for all $1 \leq j \leq m$ we have $x \pmod{\mathcal{M}_j^{oj}} \in S_j$: manifestly, this is $R$. By Theorem 2.7b), $R_j$ is a local Cohen-Kaplansky domain. Finally, by part b) each of $(R_j)_{M_j \cap R_j}$ and $R_{M_j \cap R}$ is the composite of $\mathcal{R}_{M_j}$ and $S_j$ over $\mathcal{R}/\mathcal{M}_j^{oj}$, so they are equal.

\[ \square \]

3. The Proofs

3.1. Proofs of Theorems 1.3 and 1.4. By Remark 2.5 there are primefree CK($n$)-domains for $n \in [3,5]$, and by Theorem 1.2 if $p_1 < \ldots < p_m$ are primes there is a primefree CK($\sum_{j=1}^{m} (p_j + 1)$)-domain. Thus to prove Theorem 1.3, that primefree CK($n$)-domains exist for all $n \geq 3$ it is enough to prove Theorem 1.4, that every $n \geq 6$ is of the form $\sum_{j=1}^{m} (p_j + 1)$ for primes $p_1 < \ldots < p_m$ (Theorem 1.4).

\textbf{Step 1:} We show that for all $n \geq 18$, there is a prime in the interval $(\frac{n}{2} - 1, n - 7]$. The values $18 \leq n \leq 51$ can easily be checked by hand, so we may suppose $n \geq 52$. We will make use of a sharpening of Bertrand’s postulate due to Nagura [Na52]: for all $x \geq 25$, there is a prime in the interval $[x, \frac{6x}{5}]$. Applying this with $x = \frac{n}{2} - 1$ we find that there is a prime number in the interval $\left(\frac{n}{2} - 1, \frac{3n}{5} - \frac{6}{5}\right]$ hence also in the larger interval $\left(\frac{n}{2} - 1, n - 7\right]$.

\textbf{Step 2:} It suffices to show that for all $j \geq 0$, every $n \in [6, 17 \cdot 2^j]$ is a sum of distinct $p_j + 1$'s. We show this by induction on $j$. The base case $j = 0$ is an easy computation. Suppose the result holds for some $j \geq 0$, and let $n \in (17 \cdot 2^j, 17 \cdot 2^{j+1}]$. By Step 1, there is a prime number $p \in (\frac{n}{2} - 1, n - 7]$, so

$$6 \leq n - (p + 1) < \frac{n}{2} \leq 17 \cdot 2^j.$$ 

By induction there are primes $p_1 < \ldots < p_m$ such that $n - (p + 1) = \sum_{j=1}^{m} (p_j + 1)$, and thus $n = \sum_{j=1}^{m} (p_j + 1) + (p + 1)$. Since $p + 1 > \frac{n}{2}$, we have $p_j + 1 < \frac{n}{2}$ for all $j$, so $p > p_m$ and we have written $n$ as a sum of distinct $p_j + 1$'s.

\textbf{Remark 3.1.} Theorem 1.4 is a variant of a result of H.-E. Richert [Ri49], who used Bertrand’s postulate to show that every $n \geq 7$ is the sum of distinct primes.

3.2. An Algebra Globalization Theorem.

\textbf{Theorem 3.2.} Let $q_1, \ldots, q_m$ be prime powers.
a) There is a number field $L$ and a sequence of distinct maximal ideals $m_1, \ldots, m_m$ of the ring of integers $\mathbb{Z}_L$ of $L$ such that for all $1 \leq j \leq m$ the quotient $\mathbb{Z}_L/m_j$ is a finite field of order $q_j$.

b) If there is a prime power $q$ and $b_1, \ldots, b_m$ such that $q_j = q^{b_j}$ for all $1 \leq j \leq m$, there is a finite degree field extension $L/\mathbb{F}_q(t)$ and a sequence of distinct maximal ideals $m_1, \ldots, m_m$ of the integral closure $S$ of $\mathbb{F}_q[t]$ in $L$ such that for all $1 \leq j \leq m$ the quotient $S/m_j$ is a finite field of order $q_j$.

Remark 3.3. Theorems of this kind appear in the literature. For instance, part (a) is a special case of [Ha26, Satz 1]. However, we prefer to give a self-contained argument with the number field and function field cases treated on equal footing.

Proof of Theorem 3.2.

Step 1: Let $K$ be a field, and let $v_1, \ldots, v_{g+1}$ be inequivalent discrete valuations on $K$. For $1 \leq i \leq g + 1$ let $\tilde{K}_i$ denote the completion of $K$ at $v_i$. Let $d \in \mathbb{Z}^+$. For $1 \leq i \leq g + 1$, let $L_i$ be an étale $K_i$-algebra — i.e., a finite product of finite degree separable field extensions of $K_i$ — with $\text{dim}_{K_i} L_i = d$ and such that $L_{g+1}$ is a field. Then by Krasner’s Lemma and weak approximation, there is a separable field extension $L/K$ of degree $d$ and for all $1 \leq i \leq g + 1$ a $K_i$-algebra isomorphism $K \otimes_{K_i} \tilde{K}_i \cong L_i$. (We may write each $A_i$ as $\tilde{K}_i[t]/(f_i(t))$ for a separable polynomial $f_i \in \tilde{K}_i$. Then we may take $L = K[t]/(f(t))$ where for all $i$, the coefficients of $f$ are sufficiently close to those of $f_i$ in the $v_i$-adic topology. Thus we get a separable $K$-algebra $L$. The condition that $L_{g+1}$ is a field ensures that $L$ is a field.)

Step 2: Recall that for all $d \in \mathbb{Z}^+$ there is a $p$-adic field with residue field $\mathbb{F}_{p^d}$: we may take the unique degree $d$ unramified extension of $\mathbb{Q}_p$. Let $g \in \mathbb{Z}^+$ be such that $q_1, \ldots, q_{j_1}$ are all powers of a prime $p_1$, $q_{j_1+1}, \ldots, q_{j_2}$ are all powers of a prime $p_2$, and so forth, up to $q_{j_{g-1}+1}, \ldots, q_{j_g}$ — note $j_g = m$ — all powers of $p_g$. Put $j_0 = 0$. Let $K = \mathbb{Q}$, for $1 \leq i \leq g$ let $v_i = \text{ord}_{p_i}$, and let

$$L_i = \left( \prod_{j \in [j_{i-1}+1, j_i]} L_j \right) \times M_i$$

be a finite product of $p$-adic fields such that the residue cardinality of the valuation ring of $L_i$ is $q_i$ and $M_i$ is a “fudge field” chosen so that there is $D \in \mathbb{Z}^+$ such that $\text{dim}_{Q_i} L_i = D$ for all $1 \leq i \leq g$. The field extension $L/K$ obtained by the construction of Step 1 is the desired number field in part a).

Step 3: Suppose we are in the case considered in part b). For all $d \in \mathbb{Z}^+$, $\mathbb{F}_{q^d}((t))$ is a finite extension of $\mathbb{F}_q((t))$ with residue field $\mathbb{F}_{q^d}$. We proceed as in Step 2 but with $K = \mathbb{F}_q((t))$, $g = 1$, $v_1 = \text{ord}_t$, and $v_2 = \text{ord}_{t^{-1}}$. \hfill \square

3.3. Proof of Theorem 1.10. a) For $1 \leq j \leq M$ we are given a primefree $CK(n_j, m_j; q)$-domain $R_j$. For $1 \leq k \leq m_j$ let $n_{jk}$ be the number of atoms in the $k$th maximal ideal of $R_j$ (under some ordering). By Theorem 2.2 there are primefree local $CK(n_{jk}, 1; q)$-domains $R_{j,1}, \ldots, R_{j,m_j}$ such that $\sum_{j,k} n_{jk} = \sum_{j=1}^M n_j$. So we may assume without loss of generality that $m_j = 1$ for all $j$.

Suppose first that $q = 0$, and for each $1 \leq j \leq M$ we are given a primefree
CK($n_j, 1; 0$)-domain $A_j$. By [CK46, Thm. 9], the completion $\overline{A_j}$ of the local ring $A_j$ is also a CK($n_j, 1; 0$)-domain, so it is no loss of generality to assume that each $A_j$ is complete. Let $\overline{A_j}$ be the integral closure of $A_j$, a complete DVR, say with maximal ideal $(\pi_j)$. Let $(A_j : \overline{A_j}) = (\pi_j^{e_j})$. By Theorem 2.7, $A_j$ is the composite of $\overline{A_j}$ and $S_j = A_j/(A_j : \overline{A_j}) = A_j/(\pi_j^{e_j})$ over $(A_j : \overline{A_j}) = (\pi_j^{e_j})$.

Since $\overline{A_j}$ is a complete DVR of characteristic 0 with finite residue field $\mathbb{F}_{q_j^{e_j}}$, its fraction field $L_j$ is a finite extension of $\mathbb{Q}_{p_j}$. Arguing as in the proof of Theorem 3.2 there is a number field $L$ and a set of finite places $v_1, \ldots, v_M$ of $L$ such that for all $j$, the completion of $L$ at $v_j$ is isomorphic to $L_j$. Let $M_1, \ldots, M_M$ be the corresponding maximal ideals of the ring of integers $\mathbb{Z}_L$ of $L$, and let $D$ be the localization of $\mathbb{Z}_L$ at $\mathbb{Z}_L \setminus \bigcup_{j=1}^M M_j$, so $D$ is a semilocal PID with precisely $M$ maximal ideals $M_1, \ldots, M_M$. Moreover, for $1 \leq j \leq M$ we may identify the completion of $D$ with respect to $M_j$ with $\overline{A_j}$, $M_j\overline{A_j}$ with $(\pi_j)$ and $D/M_j^{e_j}$ with $\overline{A_j}/(\pi_j^{e_j})$ and thus we may view $S_j$ as a subring of $D/M_j^{e_j}$. Let $R_j$ be the composite of $D$ and $S_j$ over $M_j^{e_j}$ and $R = \bigcap_{j=1}^M R_j$. By Corollary 2.9, $R$ is a Cohen-Kaplansky domain with $M$ maximal ideals $\{m_j = M_j \cap R\}_{j=1}^M$ and we have $R_m = (R_j)_{M_j \cap R_j}$ and the completion of $R_m$ is $A_j$. Thus $R$ is a primefree CK($\sum_{j=1}^M n_j, M; 0$)-domain.

Now suppose that $q \neq 0$, and for each $1 \leq j \leq M$ we are given a primefree CK($n_j, 1; q$)-domain $A_j$. Then $\overline{A_j}$ is a complete DVR with finite residue field which is an $\mathbb{F}_q$-algebra, so its fraction field $L_j$ is a finite extension of $\mathbb{F}_q(t)$. We now argue as above except taking $L$ to be a finite extension of $\mathbb{F}_q(t)$ and $D$ to be the subring of $L$ consisting of functions regular at the places $v_1, \ldots, v_M$.

b) Let $q_1 = p_1^{a_1}, \ldots, q_m = p_m^{a_m}$ be prime powers and $d_1, \ldots, d_m \geq 2$. For $1 \leq j \leq m$ let $K_j$ be the unramified extension of $\mathbb{Q}_{p_j}$ of degree $a_jd_j$, let $\overline{A_j}$ be its valuation ring, with maximal ideal $(\pi_j)$, let $r_j : \overline{A_j}/(\pi_j) \to \mathbb{F}_{q_j}$, and let $A_j = r_j^{-1}(\mathbb{F}_q)$. By Theorem 2.6 $A_j$ is a (necessarily primefree) CK($\sum_{j=1}^m q_j^{a_j-1}, 1; 0$)-domain. Applying part a), we get that there is a primefree CK($\sum_{j=1}^m q_j^{a_j-1}, 1; 0$)-domain.

Now suppose there is a prime power $q$ such that each $q_j$ is a power of $q = p^a$. Then $p_1 = \ldots = p_m = p$ and $a_1, \ldots, a_m$ are all divisible by $a$. We run through the argument as above but with $K_j = \mathbb{F}_{q_j^{a_j/a}}(t)$ for all $j$.

3.4. Recalled Results and Conjectures in Additive Number Theory.

**Theorem 3.4** (Sylvester [Sy84]). Let $x, y$ be coprime positive integers. Then:

a) The equation $ax + by = xy - x - y$ has no solution in non-negative integers $a, b$.

b) For all $N \geq xy - x - y + 1 = (x - 1)(y - 1)$, there are non-negative integers $a, b$ such that $ax + by = N$.

**Remark 3.5.** Let $x, y \in \mathbb{Z}^+$ with $\gcd(x, y) = d$. Theorem 3.4 implies: if $N \geq \frac{(x - d)(y - d)}{d}$ and $d \mid N$, then there are non-negative integers $a, b$ such that $ax + by = N$.

**Theorem 3.6** (Helfgott [He15]). Every odd $n \geq 7$ is a sum of three primes.

**Conjecture 3.7** (Goldbach). Every even $n \geq 4$ is a sum of two primes.
Theorem 3.8 (Chudakov [Ch37, Ch38], Estermann [Es38], van der Corput [vdC37]). The set of even integers which are sums of two primes has relative density 1 in the set of even positive integers (and thus density $\frac{1}{2}$).

Conjecture 3.9 (Schinzel). Let $f(x) = x^2 + bx + c$, where $b$ and $c$ are integers of opposite parity and $3 \nmid b$. There is a constant $N_0 = N_0(f)$ such that for all odd integers $n > N_0$ not belonging to $f(\mathbb{Z})$, there are primes $p_1$ and $p_2$ with $n = f(p_1) + p_2$.

Remark 3.10. Conjecture 3.9 is a special case of a conjecture of Schinzel [Sc63 generalizing the Goldbach conjecture. The conditions on $b, c$, and $n$ guarantee that the polynomial $n - f(x)$ is irreducible over $\mathbb{Z}$ and that $x(n - f(x))$ has no fixed divisor. Now the asymptotic prediction appearing as eq. (3) in [Sc63] implies that the number of representations of $n$ in the form $f(p_1) + p_2$ tends to infinity as $n \to \infty$.

Theorem 3.11 (van der Corput). If $f(x)$ satisfies the hypotheses of Conjecture 3.9, then the set of odd $n$ representable in the form $f(p_1) + p_2$, with $p_1$ and $p_2$ prime, has relative density 1 in the set of odd positive integers.

Proof. This is a special case of a more general theorem of van der Corput, announced in [vdC37] and proved in [vdC39]. See also [Sc61, Satz 2a].

3.5. Proof of Theorem 1.5. This follows from Theorem 2.2 and Lemma 2.3d).

3.6. Proof of Theorem 1.6. We prove parts (a) and (b) simultaneously. Let $m, n \in \mathbb{Z}^+$. We suppose: (i) $n \geq 3m$; (ii) if $n$ is even then $m \geq 3$ and $n \geq 10$; (iii) if $n$ is odd then $m \geq 4$ and $n \geq 13$.

Case 1: Suppose $m \not\equiv n \pmod{2}$. Then $n - 3(m - 3)$ is even and $n - 3(m - 3) \geq 9$, so in fact $n - 3(m - 3) \geq 10$. By Theorem 3.6 there are primes $p_1, p_2, p_3$ such that

$$n = (p_1 + 1) + (p_2 + 1) + (p_3 + 1) + \sum_{j=4}^{m} (2 + 1).$$

Case 2: Suppose $m \equiv n \pmod{2}$. Then $m \geq 4$. Moreover $n - 3(m - 4) \geq 12$ and is even. If $n - 3(m - 4) = 12$ then $n = 3m = \sum_{j=1}^{m} (2 + 1)$. Otherwise $n - 3(m - 4) \geq 14$, so $n - 3(m - 4) - (3 + 1) \geq 10$ and is even, so by Theorem 3.6 there are primes $p_1, p_2, p_3$ such that

$$n = (p_1 + 1) + (p_2 + 1) + (p_3 + 1) + (3 + 1) + \sum_{j=5}^{m} (2 + 1).$$

In all cases Theorem 1.10 applies to show there is a primefree $\text{CK}(n, m; 0)$-domain.

(c) By part (a), we may assume that $n$ is odd. We appeal to a generalization due to Schwarz of Vinogradov’s “three primes theorem” [Sc60, Hauptsatz, p. 25]. Schwarz’s result implies that all sufficiently large odd $n$ are representable in the form $(p_1^2 + p_1 + 1) + (p_2 + 1) + (p_3 + 1)$. Apply Theorem 1.10.
3.7. Proof of Theorem 1.7. a) If $n + 2 = (p_1 + 1) + (p_2 + 1)$ for some primes $p_1$ and $p_2$, then $n$ is not a sum of two integers of the form $p + 1$. According to Theorem 3.8, the set of even $n$ for which $n + 2$ is so representable has relative density 1 in the set of even positive integers. Similarly, if $n = (p_1^2 + p_1 + 1) + (p_2 + 1)$ for some primes $p_1$ and $p_2$, then $n$ is a sum of two integers of the form $p + 1$. Theorem 1.10a applies to show there is a primefree $CK(n, 2; 0)$-domain. Theorem 3.11, with $f(x) = x^2 + x + 2$, implies that the set of odd $n$ so representable has relative density 1 in the set of odd numbers.

b) We argue as in part a) but apply Conjecture 3.7 instead of Theorem 3.8.

c) If $f(x) = x^2 + x + 2$, the condition $n \neq f(x)$ is satisfied by all odd integers $n$. Now we argue as in part a) but apply Conjecture 3.9 instead of Theorem 3.11.

3.8. Proof of Theorem 1.9. Let $n$ be a prime number such there is a primefree $CK(n, 1)$-domain. By Theorem 2.4b), $n$ is of the form $\frac{q^2 - 1}{q - 1}$. By a result of Bateman-Stemmler [BS62], the number of primes $n \leq x$ of this form is at most $\frac{50\sqrt{x}}{\log x}$, for all sufficiently large $x$. The result now follows from the Prime Number Theorem: $\pi(x) = \#\{\text{primes } p \leq x\} \sim \frac{x}{\log x}$.

3.9. Proof of Theorem 1.11. a) Let $R$ be a primefree atomic domain which is an $F_\mathfrak{a}$-algebra. We may assume $R$ is Cohen-Kaplansky, for otherwise it has infinitely many atoms. Let $\mathfrak{m}$ be a maximal ideal of $R$. By Theorem 2.2, $R$ has at least as many atoms as $R_\mathfrak{m}$, so we may assume that $(R, \mathfrak{m})$ is local. Then $R/\mathfrak{m} \cong F_{\mathfrak{a}^r}$ and by Lemma 2.3c) $R$ has at least $\#P^{d-1}(F_{\mathfrak{a}^r}) \geq \#P^1(F_q) = q + 1$ atoms.

b) Let $n \geq 8$. Taking $a = 2 + 1, b = 4 + 1$ in Theorem 3.4, we get that there are $x, y \in \mathbb{N}$ such that $x(2 + 1) + y(4 + 1) = n$. By Theorem 1.10 there is a primefree $CK(n, x + y)$-domain of characteristic 2. The equation $x(2 + 1) + y(4 + 1) = n$ also has a solution in non-negative integers $x, y$ for $n \in \{3, 5, 6\}$, so there is a primefree $CK(n)$-domain of characteristic 2 for these values as well. For $n \in \{4, 7\}$ there is a primefree $CK(n, 1)$-domain of characteristic 2 by Theorem 2.4c).

c) By Theorem 2.4 there are a primefree $CK(n, 1; q)$-domains for $n \in \{q + 1, 2q\}$, so by Theorem 1.10 for all $a, b \in \mathbb{N}$ there is a primefree $CK(a(q + 1) + b(2q), a + b; q)$-domain. Because $q$ is a power of 2, $q + 1$ and $2q$ are coprime, so by Theorem 3.4 every $n \geq (q + 1)(2q - 1) = 2q^2 - q$ is of the form $a(q + 1) + b(2q)$ for $a, b \in \mathbb{N}$.

d) Theorem 2.4 gives primefree $CK(n, 1; q)$-domains for $n \in \{q + 1, 2q, q^2 + q + 1\}$, so by Theorem 1.10 for all $a, b, c \in \mathbb{N}$ there is a primefree $CK(a(q + 1) + b(2q) + c(q^2 + q + 1), a + b + c; q)$-domain. Since $q$ is odd we have gcd$(q + 1, 2q) = 2$, so by Remark 3.5 every even $n \geq (q - 1)^2$ is of the form $a(q + 1) + b(2q)$ for $a, b \in \mathbb{N}$. If $n \geq 2q^2 - q + 1$ is odd, then $n \geq 2q^2 - q + 2$ and $n - (q^2 + q + 1) \geq (q - 1)^2$ is even.

3.10. Concerning Conjecture 1.8. By Theorem 1.5 if there is a $CK(n, 2)$-domain then $n \geq 6$ and if there is a $CK(n, 3)$-domain then $n \geq 9$. Using PARI/GP, we computed that there are 168 odd integers below $10^{10}$ not expressible in the form $(p_1^2 + p_1 + 1) + (p_2 + 1)$, the largest being 1446379. Using Mathematica, we checked that the 165 exceptional integers lying in $[7, 10^{10}]$ nevertheless can be represented as a sum of two integers of the form $\frac{q^2 - 1}{q - 1}$. Combined with Conjecture 3.7, we view this as evidence that all integers $n \geq 6$ admit a representation in that form. This
would imply that there is a primefree $\text{CK}(n, 2; 0)$-domain for all $n \geq 6$. If so, then as above for all $n \geq 6$ there is a primefree $\text{CK}(n + 3, 3; 0)$-domain, so the first part of Conjecture 1.8 implies the second.

Combining our computations with the verification of the Goldbach conjecture to $4 \cdot 10^{18}$ [OHP14], it follows that both parts of Conjecture 1.8 hold for $n \leq 10^{10}$.

4. Final Comments

4.1. The connection with orders. Coykendall-Spicer construct the domains used to prove Corollary 1.2 using local orders: for $S$ a finite nonempty set of primes, let $\mathbb{Z}^S$ be the localization of $\mathbb{Z}$ with respect to $\mathbb{Z} \setminus \bigcup_{p \in S} (p)$. Let $K$ be any number field such that for all $p \in S$, there is a unique prime of $\mathbb{Z}_K$ lying over $p$. Then the normalization $\mathcal{R}$ of $\mathbb{Z}^S$ in $K$ is a semilocal PID with $m$ maximal ideals. Let $R$ be any $\mathbb{Z}^S$-order in $K$: i.e., a finitely generated $\mathbb{Z}^S$-subalgebra of $K$ with fraction field $K$. Then $R$ is a Cohen-Kaplansky domain (cf. [CS12, §2]). One can replace $\mathbb{Z}^S$ with any semilocal PID $A$ with finite residue fields.

The proof of Theorem 1.10 shows that for every primefree $\text{CK}(n; 0)$-domain $R$ there is an order $\mathcal{O}$ in a number field $K$ and a finite set $S$ of maximal ideals of $\mathcal{O}$ such that the group of divisibility of $R$ is isomorphic to the group of divisibility of $\mathcal{O}^S = (\mathcal{O} \setminus \bigcup_{m \in S} (m))^{-1}\mathcal{O}$. Here we have a localized order rather than a $\mathbb{Z}^S$-order. But as in the proof of Theorem 1.10, one sees that every group of divisibility of a local Cohen-Kaplansky domain in characteristic zero arises as a $\mathbb{Z}^{(p)}$-order in a number field, and that in positive characteristics the same holds with $\mathbb{Z}^{(p)}$ replaced by the localization of $\mathbb{F}_p[t]$ at an irreducible polynomial. It would be interesting to compute the number of irreducibles in various local orders.

4.2. A better Globalization Theorem? The main algebraic problem considered in this paper is the following:

**Question 3.** Let $R_1, \ldots, R_m$ be primefree Cohen-Kaplansky domains with $n_1, \ldots, n_m$ atoms. Is there a primefree Cohen-Kaplansky domain with $\sum_{j=1}^m n_j$ atoms?

Theorem 1.10 answers this question in the affirmative when $R_1, \ldots, R_m$ all have the same characteristic. Perhaps this is the only “natural” case: in what reasonable sense can domains of different characteristics be combined? But from the perspective of Question 2 it would be nice if one could combine local building blocks of different characteristics. Could it be that whenever there is a primefree $\text{CK}(n, 1; q)$-domain for $q > 0$ there is also a primefree $\text{CK}(n, 1; 0)$-domain?

We end by discussing a possible strategy for showing this. Every complete $\text{CK}(n, 1)$-domain $R$ of positive characteristic is the composite of $\mathbb{F}_q[[t]]$ and a subring $S$ of $\mathbb{F}_q[[t]]/(t^e)$ over $(t^e)$. Every ring $\mathbb{F}_q[[t]]/(t^e)$ has an isomorphic copy $\mathcal{O}_K/\mathcal{M}^e$, where $K$ is a $p$-adic field with valuation ring $\mathcal{O}_K$ and maximal ideal $\mathcal{M}$ [Ne71]. Thus we can build the “corresponding characteristic 0 CK-domain” $\hat{R}$: the composite of $\mathcal{O}_K$ and the isomorphic copy of $S$ over $\mathcal{M}^e$. Does $\hat{R}$ have the same number of irreducibles as $R$? The group of divisibility of $R$ is isomorphic to $\mathbb{Z} \oplus (\mathbb{F}^+/(\mathbb{F}^*; F, \mathcal{T}))^*$ [AM92, Thm. 4.4]. But this is an isomorphism of abstract groups, whereas to count atoms we need the isomorphism to respect the partial orderings. (The atoms are the minimal nonzero elements of the positive cone.) Do these composites have isomorphic order structure? If so, then Question 3 has an affirmative answer.
THE NUMBER OF ATOMS IN AN ATOMIC DOMAIN
