Abstract
While a generic smooth Ribaucour sphere congruence admits exactly two envelopes, a discrete R-congruence gives rise to a 2-parameter family of discrete enveloping surfaces. The main purpose of this paper is to gain geometric insights into this ambiguity. In particular, discrete R-congruences that are enveloped by discrete channel surfaces and discrete Legendre maps with one family of spherical curvature lines are discussed.

1 Introduction
Classically, a smooth 2-parameter family of spheres is called Ribaucour sphere congruence if its two enveloping surfaces have corresponding curvature lines. Since a smooth sphere congruence admits at most two envelopes, each such sphere congruence provides a Ribaucour pair of surfaces. Over the decades, this transformation concept was extended to submanifolds, partly also with singularities, [15–17,28,30] and various (integrable) approaches for the construction were discussed [8,18,31]. In these developments, special interest was paid to constrained Ribaucour transformations that allow to generate envelopes with special geometric properties, for example, the Darboux transformation of isothermic surfaces and Ribaucour transformations that preserve classes of O-surfaces [26].

A characteristic feature in the theory of smooth Ribaucour transformations are permutability theorems. In discrete differential geometry, those became crucial as underlying concept of integrable discretizations of curvature-line parametrized surfaces and orthogonal coordinate systems [4,6].
Discrete equivalents of Ribaucour sphere congruences were developed in [6] and [19]: discrete R-congruences are provided by $Q$-nets in the Lie quadric, that is, a discrete congruence of spheres with planar faces. However, more flexibility in the discrete setup results in a 2-parameter family of discrete envelopes; we call it the Ribaucour family of a discrete R-congruence (cf. Definition 3.7).

In the last years, in a variety of works, discrete Ribaucour transformations between general discrete surfaces were discussed [9,20,25]. Furthermore, restricted transformations for particular classes of discrete surfaces as discrete (special) isothermic surfaces [4,11,12,22,23] and discrete O-surfaces [29] were investigated, to name just a few.

However, to the best of the authors’ knowledge, there are no systematic studies of the geometry of the entire Ribaucour families in the literature, since usually pairs of discrete envelopes are considered as the main objects. Geometric investigations of this 2-parameter family of envelopes is the main contribution of this work. In most parts we consider the discrete R-congruences as the primary objects of interest and explore the corresponding Ribaucour families by using data provided by the sphere congruence.

This paper is organized as follows. In Sect. 2 we recall basic principles and constructions in Lie sphere geometry. Section 3 is devoted to the construction of envelopes of discrete R-congruences. As a crucial result, for any face of a discrete R-congruence, we introduce two involutive Lie inversions that map adjacent contact elements of discrete envelopes onto each other (Proposition 3.2). Using these inversions, we obtain a construction of a unique envelope from one prescribed initial contact element. Hence, in this way, we can parametrize the entire Ribaucour family of a discrete R-congruence. To conclude this section, we discuss some examples of special discrete R-congruences. This reveals relations to recent works on discrete Ribaucour coordinates [9] and discrete $\Omega$-surfaces [7]. Since we consider the discrete R-congruence as primary object, our approach sheds light on these situations from a different point of view.

In Sect. 4 we focus on the geometry of the envelopes in a general Ribaucour family. We discuss how the choice of a facewise constant Lie inversion decomposes a Ribaucour family into pairs of envelopes (cf.Sect. 4.2). Those Lie inversions then interact well with face-cyclides of these Ribaucour pairs and, therefore, induce a Ribaucour transformation of cyclidic nets as pointed out in Sect. 4.3.

As an application of the developed framework for discrete R-congruences, we investigate envelopes with one family of spherical curvature lines in Sect. 5. In particular, we characterize sphere congruences of Ribaucour families containing at least two discrete channel surfaces.

## 2 Preliminaries

In this section we briefly summarize some basic principles of Lie sphere geometry and recall some concepts that will be crucial for the rest of this work. For more details on this topic, the interested reader is referred to Blaschke [1] and Cecil [13].

Throughout the paper we use the hexaspherical model introduced by Lie and work in the vector space $\mathbb{R}^{4,2}$ endowed with the inner product $\langle \cdot , \cdot \rangle$ given by

$$\langle x, y \rangle = -x_1y_1 + x_2y_2 + x_3y_3 + x_4y_4 + x_5y_5 - x_6y_6.$$ 

The projective light cone will be denoted by $\mathbb{P}(\mathcal{L})$ and represents the set of oriented 2-spheres in $\mathbb{S}^3$ in this model. Two spheres $r, s \in \mathbb{P}(\mathcal{L})$ are in oriented contact if and only if $\langle r, s \rangle = 0,$
where \( r \) and \( s \) denote homogeneous coordinates of the spheres \( r \) and \( s \), respectively. Thus, the set \( Z \) of lines in \( \mathbb{P}(L) \) corresponds to contact elements.

Homogeneous coordinates of elements in the projective space \( \mathbb{P}(\mathbb{R}^{4,2}) \) will be denoted by the corresponding black letter. If statements hold for arbitrary homogeneous coordinates we do this without explicitly mentioning it.

By breaking symmetry, we can recover various subgeometries of Lie sphere geometry. Thus, let \( p \in \mathbb{R}^{4,2} \) be a vector that is not lightlike, i.e., \( \langle p, p \rangle \neq 0 \). If \( p \) is timelike, then \( \langle p \rangle \perp \cong \mathbb{R}^{4,1} \) defines a Riemannian conformal geometry, that is, a Möbius geometry. In this case, elements in \( \mathbb{P}(L) \cap \langle p \rangle \perp \) are considered points and will be called point spheres. If \( p \) is spacelike, it determines a Lorentzian conformal geometry \( \langle p \rangle \perp \cong \mathbb{R}^{3,2} \) or planar Lie geometry.

### 2.1 Linear systems and linear sphere complexes

Let \( W \) be a non-degenerate, indefinite projective plane, then the 1-parameter family \( W \cap \mathbb{P}(L) \) of spheres is called a **linear system**\(^1\). If this family of spheres lies in the span of the three spheres \( s_1, s_2, s_3 \in \mathbb{P}(L) \), the Lie invariant

\[
\delta := \text{sign}\{\langle s_1, s_2 \rangle, \langle s_2, s_3 \rangle, \langle s_3, s_1 \rangle\}
\]

provides information about the geometric configuration:

- If \( \delta = -1 \), then \( W \) is a \((2, 1)\)-plane. Hence, the spheres of the linear system are curvature spheres of a Dupin cyclide and there exists a 1-parameter family of spheres in oriented contact with all spheres of the linear system—the spheres of the orthogonal \((2, 1)\)-plane.
- If \( \delta = 1 \), then \( W \) is a \((1, 2)\)-plane. Thus, there does not exist a sphere that is in oriented contact with all spheres of the linear system, since the orthogonal complement is a \((3, 0)\)-plane that does not contain any spheres.

Any element \( a \in \mathbb{P}(\mathbb{R}^{4,2}) \) defines a **linear sphere complex** \( \mathbb{P}(L) \cap a \perp \), a 3-dimensional family of 2-spheres. Depending on the type of the vector \( a \), we distinguish three cases:

- **parabolic** linear sphere complex, \( \langle a, a \rangle = 0 \): all spheres in the complex are in oriented contact with the sphere defined by \( a \); hence, all spheres in the contact elements that contain the sphere \( a \) provide the linear sphere complex.
- **hyperbolic** linear sphere complex, \( \langle a, a \rangle < 0 \): if we fix a Möbius geometry by choosing \( a \) as the point sphere complex, then the linear sphere complex consists of all point spheres.
- **elliptic** linear sphere complex, \( \langle a, a \rangle > 0 \): in a Möbius geometry, these linear sphere complexes then consist of all contact elements that intersect a fixed sphere at a fixed angle (see Fig. 1, left).

Since elliptic linear sphere complexes will be essential in this paper, we will discuss their geometric construction illustrated in Fig. 1 in more detail. Assume that \( a \in \mathbb{P}(\mathbb{R}^{4,2}) \) determines an elliptic linear sphere complex. Additionally fix a parabolic complex \( q \), as well as a hyperbolic complex \( p \) to distinguish a Möbius geometry modelled on \( p \perp \).

Without loss of generality, we choose \( q = (1, -1, 0, 0, 0, 0) \), \( p = (0, 0, 0, 0, 0, 1) \) and homogeneous coordinates \( a = (a_i)_i \in \mathbb{R}^{4,2} \) of \( a \) such that \( \langle a, q \rangle = 1 \). By defining

\[
c := (a_3, a_4, a_5), \quad R := \sqrt{1 + \|c\|^2 - 2a_1}, \quad \text{and} \quad r := \langle a, p \rangle,\]

\(^1\) [1, §53]: Lineare Kugelscharen und Kugelkomplexe
we obtain two concentric spheres \( s_r \) and \( s_R \) with center \( c \) and radii \( r \) and \( R \), respectively (see Fig. 1, left). Then a straightforward computation shows that any sphere \( s \) in the elliptic linear sphere complex \( \langle a \rangle \perp \) intersects the sphere \( s_R \) under the constant oriented angle \( \cos \gamma = \frac{r}{R} \). If \( \langle a, q \rangle = 0 \), the sphere \( s_R \) corresponds to a plane and the sphere \( s_r \) becomes the point at infinity.

### 2.2 Lie inversions

Let \( a \in \mathbb{P}(\mathbb{R}^{4,2}), \langle a, a \rangle \neq 0 \), then the Lie inversion with respect to the linear sphere complex determined by \( a \) is given by

\[
\sigma_a : \mathbb{R}^{4,2} \rightarrow \mathbb{R}^{4,2}, \quad \sigma_a(r) := r - \frac{2\langle r, a \rangle}{\langle a, a \rangle} a.
\] (1)

Lie inversions are involutive linear maps that preserve oriented contact between spheres and, therefore, also contact elements. Moreover, from the definition, we directly conclude that spheres contained in the linear sphere complex \( \mathbb{P}(\mathcal{L}) \cap a^\perp \) are fixed by the Lie inversion \( \sigma_a \).

**Lemma 2.1** Let \( r, s \in \mathbb{P}(\mathcal{L}), \langle r, s \rangle \neq 0 \), be two spheres that do not lie in the linear sphere complex \( \mathbb{P}(\mathcal{L}) \cap a^\perp \) with \( \langle a, a \rangle \neq 0 \). Then, the span \{\( r, s, \sigma_a(r), \sigma_a(s) \)\} \( \cap \mathbb{P}(\mathcal{L}) \) is a linear system.

The following two constructions give Lie inversions that map prescribed spheres onto each other:

**Lemma 2.2** Let \( \langle r \rangle = r \) and \( \langle \bar{r} \rangle = \bar{r} \) be fixed homogeneous coordinates of two spheres that are not in oriented contact and let \( \sigma_{\bar{r}} \) denote the Lie inversion with respect to the linear sphere complex \( \mathbb{n}_{\bar{r}} := r - \lambda \bar{r}, \) where \( \lambda \in \mathbb{R}^\times \). Then the following properties hold:

(i) For any \( \lambda \in \mathbb{R}^\times \), the Lie inversion \( \sigma_{\lambda} \) maps the sphere \( r \) to the sphere \( \hat{r} \).

(ii) All spheres in oriented contact with \( r \) and \( \hat{r} \) are fixed by any Lie inversion \( \sigma_{\lambda} \).

(iii) A contact element that contains \( r \) is mapped by any Lie inversion \( \sigma_{\lambda}, \lambda \in \mathbb{R}, \) to the same contact element; however, different Lie inversions induce different correspondences between the spheres in the two contact elements.
Proof The properties (i) and (ii) follow directly from equation (1). To prove the third statement, we suppose that \( v \in \mathbb{P}(\mathbb{L}) \) is a sphere in oriented contact with the sphere \( r \) and \( \langle v, \bar{r} \rangle \neq 0 \). Then, the sphere
\[
\tilde{s} := \langle v, \bar{r} \rangle r - \langle r, \bar{r} \rangle v
\]
lies in the contact element \( f := \text{span}\{r, v\} \) and, furthermore, for any \( \lambda \in \mathbb{R} \) in the linear sphere complex \( \langle n_\lambda \rangle_{\perp} \). Hence, any Lie inversion \( \sigma_\lambda \) preserves the sphere \( \tilde{s} \) and maps the contact element \( f \) to the contact element \( \sigma_\lambda(f) = \text{span}\{\tilde{s}, \bar{r}\} \).

\[\Box\]

Lemma 2.3 Let \( f \) and \( \bar{f} \) be two contact elements sharing a common sphere \( s \in \mathbb{P}(\mathbb{L}) \). Then, for four spheres \( r, t \in f \) and \( \bar{r}, \bar{t} \in \bar{f} \) that do not coincide with \( s \), there exists a unique Lie inversion \( \sigma \) satisfying
\[
\sigma(r) = \bar{r} \quad \text{and} \quad \sigma(t) = \bar{t}.
\]

Proof By assumption, there exist constants \( \lambda, \mu, \bar{\lambda}, \bar{\mu} \in \mathbb{R} \times \) such that
\[
s = \lambda r + \mu t \quad \text{and} \quad s = \bar{\lambda} \bar{r} + \bar{\mu} \bar{t}.
\]
Then, the Lie inversion with respect to the linear sphere complex \( a \in \mathbb{P}(\mathbb{R}^{4,2}) \) determined by
\[
a := \lambda r - \bar{\lambda} \bar{r} = \bar{\mu} \bar{t} - \mu t
\]
provides the sought-after map. Moreover, \( a \) is the intersection of the lines \( \text{span}\{r, \bar{r}\} \) and \( \text{span}\{t, \bar{t}\} \) and hence unique.

\[\Box\]

For later reference, we remark the following property for the composition of two Lie inversions that follows from straightforward computations:

Lemma 2.4 Two Lie inversions commute, \( \sigma_a \circ \sigma_b = \sigma_b \circ \sigma_a \), if and only if the corresponding linear sphere complexes are involutive, that is, \( \langle a, b \rangle = 0 \).

2.3 Cross-ratio of four spheres

Similar to the cross-ratio of four concircular points, one defines the cross-ratio of four spheres in a linear system. We recall this definition and different ways to compute it.

Definition 2.5 Let \( r_1, r_2, r_3, r_4 \in \mathbb{P}(\mathbb{L}) \) be four spheres in a common contact element, then the **cross-ratio** is defined by
\[
cr(r_1, r_2, r_3, r_4) = \frac{\alpha \beta}{\bar{\alpha} \bar{\beta}}, \quad \text{where} \quad r_3 = \alpha r_1 + \beta r_2 \quad \text{and} \quad r_4 = \bar{\alpha} r_1 + \bar{\beta} r_2.
\]

It is independent of the choice of homogeneous coordinates and can be equivalently described by the four radii of the spheres
\[
cr(r_1, r_2, r_3, r_4) = \frac{(R_1 - R_4)(R_2 - R_3)}{(R_1 - R_3)(R_2 - R_4)},
\]
where \( R_i \) denotes the radius of the sphere \( r_i \) (for point spheres the radius is assumed to be 0 and for a plane we define the radius as \( \infty \)).

Moreover, one can define the **cross-ratio of four spheres in a linear system** by tracking it back to the cross-ratio of four spheres in a contact element: assume that \( r_1, r_2, r_3 \) and \( r_4 \) are
four spheres in a linear system and choose an arbitrary contact element \( f \ni r_1 \). Then there exist three unique spheres \( s_i \) in \( f \) such that \( s_i \perp r_i \) for \( i = 2, 3, 4 \) and we define

\[
\text{cr}(r_1, r_2, r_3, r_4) := \text{cr}(r_1, s_2, s_3, s_4).
\]

In particular, the cross-ratio of four spheres that are pairwise related by a Lie inversion is given by the following formula (cf. [1, §53]):

**Lemma 2.6** Let \( a \in \mathbb{P}^4(L) \) and \( s_1, s_2 \in \mathbb{P}(L) \) be two spheres that do not lie in the linear sphere complex \( a^\perp \), then

\[
\text{cr}(s_1, s_2, \sigma_a(s_2), \sigma_a(s_1)) = \frac{\langle s_1, s_2 \rangle \langle a, a \rangle}{2 \langle s_1, a \rangle \langle s_2, a \rangle}.
\]

### 2.4 Discrete Legendre maps

Discrete surfaces in this paper will be represented by discrete Legendre maps from a connected quadrilateral cell complex \( G = (V, E, F) \) of degree 4 to the space of contact elements \( \mathcal{Z} \). The set of vertices (0-cells), edges (1-cells) and faces (2-cells) of the cell complex \( G \) are denoted by \( V, E \) and \( F \), respectively.

The directions in the cell complex will be labelled by upper indices \((1)\) and \((2)\) and we obtain two distinguished sets of edges \( E(1) \cup E(2) = E \). A \((1)-\) resp. \((2)-\)coordinate ribbon is then the sequence of faces bounded by two adjacent \((1)-\) resp. \((2)-\)coordinate lines.

**Definition 2.7** [4,10] A discrete line congruence \( f : V \rightarrow \mathcal{Z}, i \mapsto f_i \), is a discrete Legendre map if two adjacent contact elements \( f_i \) and \( f_j \) share a common curvature sphere \( s_{ij} := f_i \cap f_j \).

Note that, for any discrete Legendre map, we therefore obtain two curvature sphere congruences \( s^{(1)} : E(1) \rightarrow \mathbb{P}(L) \) and \( s^{(2)} : E(2) \rightarrow \mathbb{P}(L) \).

Moreover, for any fixed point sphere complex \( p \in \mathbb{R}^{4,2}, \langle p, p \rangle = -1 \), the point sphere congruence \( p_i := f_i \cap p^\perp \) of a discrete Legendre map provides a circular net, that is, any four point spheres of an elementary quadrilateral are concircular.

### 3 Discrete R-congruences

Classically, a smooth sphere congruence is called Ribaucour if the curvature lines of its two envelopes correspond. Representing discrete surfaces by discrete Legendre maps, the analogous discrete problem, was studied in [6]: discrete sphere congruences enveloped by at least two generic discrete Legendre maps are given by \( Q\)-nets in the Lie quadric, i.e., sphere congruences \( q : V \rightarrow \mathbb{P}(L) \) such that the four spheres of any elementary quadrilateral are coplanar.

In this paper, we will exclude degenerate faces of a \( Q\)-net and will assume that the spheres of a quadrilateral are not in oriented contact:

**Definition 3.1** A map \( r : V \rightarrow \mathbb{P}(L) \) is called a discrete R-congruence if the four spheres of any elementary quadrilateral lie in a unique linear system.

As pointed out in [6, §5], discrete R-congruences with spheres lying in linear systems of signature \((2, 1)\) provide the natural discrete counterparts to smooth Ribaucour sphere
congruences. Furthermore, since in this case any four spheres of a quadrilateral are curvature spheres of a Dupin cyclide, these $Q$-nets often allow for elegant and straightforward geometric interpretations. Thus, in this work, we will often focus on these discrete $(2, 1)$-$R$-congruences.

**Remark** In the smooth case, Blaschke gave the following characterization of smooth Ribaucour sphere congruences [1, §77]: a smooth sphere congruence $r : U \to \mathbb{P}(L)$ is a Ribaucour sphere congruence if and only if for any choice of coordinates $(u, v)$ there exists a map of osculating complexes $t : U \to \mathbb{P}(\mathbb{R}^{4, 2})$ such that

$$\text{span}\{r, \partial_u r, \partial_v r, \partial_{uu} r, \partial_{vv} r, \partial_{uv} r\} \subset t^\perp.$$  

Similar osculating complexes also exist at vertices of a discrete $R$-congruence: by definition, the nine $R$-spheres of the four adjacent quadrilateral lie in a common linear sphere complex. This complex is spanned by the vertex sphere and its four neighbours.

Any face of a discrete $R$-congruence induces two special Lie inversions that will turn out to be crucial in the construction of its envelopes (see Fig. 2, right):

**Proposition 3.2** A discrete $R$-congruence induces a unique map of linear sphere complexes determined by

$$(n^{(1)}, n^{(2)}) : \mathcal{F} \to \mathbb{P}(\mathbb{R}^{4, 2})\setminus \mathbb{P}(L) \times \mathbb{P}(\mathbb{R}^{4, 2})\setminus \mathbb{P}(L)$$

such that for any quadrilateral $(ijkl)$ the corresponding Lie inversions $\sigma_{n^{(1)}}$ and $\sigma_{n^{(2)}}$ satisfy

$$\sigma_{n^{(1)}}(r_i) = r_j, \quad \sigma_{n^{(1)}}(r_l) = r_k$$

$$\sigma_{n^{(2)}}(r_i) = r_l, \quad \sigma_{n^{(2)}}(r_j) = r_k; \tag{2}$$

these induced Lie inversions will be denoted by

$$\sigma^{(1)} := \sigma_{n^{(1)}} \quad \text{and} \quad \sigma^{(2)} := \sigma_{n^{(2)}}.$$  

**Proof** Let $r_i, r_j, r_k$ and $r_l$ be four spheres of an elementary quadrilateral of a discrete $R$-congruence (see Fig. 2). Since the four spheres lie in a linear system and are therefore linearly dependent, we can choose homogeneous coordinates such that

$$r_i - r_j + r_k - r_l = 0. \tag{3}$$

Then, by Lemma 2.2 (i), the vectors

$$n^{(1)} := r_i - r_j = r_l - r_k \quad \text{and} \quad n^{(2)} := r_i - r_l = r_j - r_k \tag{4}$$

define two linear sphere complexes with the desired properties.

Since the choice of homogeneous coordinates in (3) is unique up to a common scaling of $r_i, r_j, r_k$ and $r_l$, the linear sphere complexes $n^{(1)}$ and $n^{(2)}$ are uniquely defined. \hfill \Box

We emphasize that the choice of homogeneous coordinates in (3) is local and depends on the quadrilateral under consideration. However, for special discrete $R$-congruences there exist global homogeneous coordinates inducing the Lie inversions $\sigma^{(1)}$ and $\sigma^{(2)}$. Such an example is provided by isothermic sphere congruences as discussed in Sect. 3.3.

**Lemma 3.3** For any quadrilateral, the two linear sphere complexes determined by $n^{(1)}$ and $n^{(2)}$ are involutive.
**Fig. 2** Left: a schematic picture of the two Lie inversions \( \sigma(1) \) and \( \sigma(2) \) of an \( R \)-congruence quadrilateral \((r_i, r_j, r_k, r_l)\). Right: a plane section through an \( R \)-congruence quadrilateral showing the two elliptic complexes \( n(1) \) and \( n(2) \) of the inversions \( \sigma(1) \) and \( \sigma(2) \).

**Proof** Without loss of generality, for any quadrilateral we choose homogeneous coordinates as given in Eq. (4). Then

\[
2\langle n(2), n(1) \rangle = \langle r_i - r_j, r_i - r_j \rangle + \langle r_j - r_k, r_j - r_k \rangle = \langle r_j, -r_i + r_k + r_l \rangle + \langle r_i, -r_i + r_j - r_k \rangle = 0.
\]

\( \square \)

**Lemma 3.4** Let \((r_i, r_j, r_k, r_l)\) be four spheres of an elementary quadrilateral of a discrete \( R \)-congruence.

(i) \( cr(r_i, r_j, r_k, r_l) < 0 \) if and only if \( n(1) \) and \( n(2) \) determine two elliptic or two hyperbolic linear sphere complexes.

(ii) \( cr(r_i, r_j, r_k, r_l) > 0 \) if and only if the linear sphere complexes determined by \( n(1) \) and \( n(2) \) are of different type, that is, one linear sphere complex is elliptic and the other one is hyperbolic.

**Proof** Suppose that \((r_i, r_j, r_k, r_l)\) are four spheres of an elementary quadrilateral of a discrete \( R \)-congruence and choose homogeneous coordinates such that \( 0 = r_i - r_j + r_k - r_l \). Then, by Lemma 2.6, we obtain that

\[
 cr(r_i, r_j, r_k, r_l) = \frac{\langle r_i, r_j \rangle \langle n(2), n(2) \rangle}{2\langle r_i, n(2) \rangle \langle r_j, n(2) \rangle} = \frac{\langle n(1), n(1) \rangle}{\langle n(2), n(2) \rangle} \quad (5)
\]

and therefore conclude that

\[
 cr(r_i, r_j, r_k, r_l) < 0 \iff \text{sign}\{\langle n(1), n(1) \rangle\} = \text{sign}\{\langle n(2), n(2) \rangle\}.
\]

The points \( n(1) \) and \( n(2) \) lie in the plane spanned by the spheres \( r_i, r_j, r_k \) and \( r_l \). Therefore, if the plane has signature \((2, 1)\), the linear sphere complexes are elliptic; if the spheres lie in a \((1, 2)\)-plane, then the linear sphere complexes are hyperbolic. Moreover, \( cr(r_i, r_j, r_k, r_l) > 0 \) if and only if

\[
 \text{sign}\{\langle n(2), n(2) \rangle\} = -\text{sign}\{\langle n(1), n(1) \rangle\},
\]

that is, if and only if the two linear sphere complexes are of different type (see Fig. 3 for the Möbius geometric picture). \( \square \)
The sign also determines the type of the Möbius inversion (resp. linear sphere complex in Lie geometry) associated to the quadrilateral. This proposition also includes the special case of four concircular point spheres. It is well-known that a circular quadrilateral is embedded if and only if the cross-ratio is negative. In this case, the Lie inversions $\sigma^{(1)}$ and $\sigma^{(2)}$ become Möbius inversions (see Fig. 3).

With the Lie inversions at hand, we are now prepared to discuss the main objects of interest, namely the envelopes of a discrete R-congruence:

**Definition 3.5** A discrete Legendre map $f : V \to Z$ is the envelope of a discrete R-congruence $r : V \to \mathbb{P}(L)$, if $r_i \in f_i$ for all $i \in V$.

Envelopes of a discrete R-congruence can be constructed from one prescribed initial contact element using the inversions defined in Proposition 3.2. Thus, suppose that $f_i := \text{span}\{s_0, r_i\}$ is an arbitrary initial contact element at the vertex $i \in V$. Then, the contact elements

$$f_j := \sigma^{(1)}(f_i), \quad f_k := \sigma^{(2)}(f_j), \quad f_l := \sigma^{(1)}(f_k) = \sigma^{(2)}(f_i)$$

define an envelope for the face $(ijkl)$ of the discrete R-congruence $r$: firstly, observe that by Lemmas 2.4 and 3.3, the contact elements $\sigma^{(1)}(f_k)$ and $\sigma^{(2)}(f_i)$ indeed coincide. Furthermore, from Proposition 3.2 and Lemma 2.2, we deduce that the contact elements envelop the discrete R-congruence,

$$r_j \in f_j, \quad r_k \in f_k \quad \text{and} \quad r_l \in f_l,$$

and two adjacent ones intersect.

Moreover, due to Lemma 2.2(iii), this construction uniquely extends to all vertices $V$ of the quadrilateral cell complex.

Conversely, any envelope of a discrete R-congruence arises in this way:

**Lemma 3.6** Let $f : V \to Z$ be a discrete Legendre map enveloping the discrete R-congruence $r : V \to \mathbb{P}(L)$, then for any quadrilateral $(ijkl)$ we obtain that

$$\sigma^{(1)}(f_i) = f_j, \quad \sigma^{(1)}(f_i) = f_k \quad \text{and} \quad \sigma^{(2)}(f_i) = f_l, \quad \sigma^{(2)}(f_j) = f_k.$$

**Proof** Assume that $f$ is an envelope, then we know that $r_i \in f_i$ and $r_j \in f_j$ (see Fig. 4 left for the labelling of a quadrilateral). Therefore, the Lie inversion $\sigma^{(1)}$ preserves the curvature sphere $s_{ij} = f_i \cap f_j$.

Hence, for any sphere $r_l + \lambda s_{ij}$ in the contact element $f_i$, it follows that the sphere

$$\sigma^{(1)}(r_l + \lambda s_{ij}) = \sigma^{(1)}(r_l) + \lambda \sigma^{(1)}(s_{ij}) = r_j + \lambda s_{ij}$$

is contained in the contact element $f_j$. This completes the proof. 

---

**Fig. 3** Whether a circular quadrilateral is embedded or non-embedded depends on the sign of the cross-ratio of the circular quadrilateral. The sign also determines the type of the Möbius inversion (resp. linear sphere complex in Lie geometry) associated to the quadrilateral.
Fig. 4  Left: an R-congruence quadrilateral \((r_i, r_j, r_k, r_l)\) with contact elements \(f\), curvature spheres \(s\), and the points \(n^{(1)}, n^{(2)}\) defining the complexes. Right: the elements with the same color are mapped onto each other by the involution \(\sigma^{(2)}\) induced by the complex \(n^{(2)}\), e.g., \(r_i \leftrightarrow r_l, s_{kl} \leftrightarrow s_{ij}\)

Thus, we have reproven the following existence result for envelopes of a discrete R-congruence that was already given in [4, Theorem 3.37]:

**Corollary and Definition 3.7**  Any envelope of a discrete R-congruence is uniquely determined by the choice of an initial contact element and, therefore, any discrete R-congruence admits a 2-parameter family of envelopes.

This family of envelopes is said to be the Ribaucour family of a discrete R-congruence. If the discrete R-congruence consists of faces with signature \((2, 1)\), the family is also called a \((2, 1)\)-Ribaucour family.

For later reference we remark on some relations between the envelopes and the Lie inversions associated to the discrete R-congruence (see Fig. 4, right):

**Lemma 3.8**  Let \(f : \mathcal{V} \to \mathcal{Z}\) be a discrete Legendre map enveloping the discrete R-congruence \(r : \mathcal{V} \to \mathbb{P}(\mathcal{L})\). Then, for any quadrilateral, the Lie inversions \(\sigma^{(1)}\) and \(\sigma^{(2)}\) swap the curvature spheres on opposite edges:

\[
\sigma^{(2)}(s_{ij}) = s_{kl} \quad \text{and} \quad \sigma^{(1)}(s_{jk}) = s_{li}.
\]

### 3.1 Möbius geometric point of view

In this subsection we briefly discuss the interplay between the construction of Ribaucour families in Lie sphere and Möbius geometry. Thus, we fix a point sphere complex \(p \in \mathbb{R}^{4,2}, \langle p, p \rangle = -1\), to distinguish a Möbius geometry modelled on \(\langle p \rangle^\perp\).

Since a Ribaucour family consists of discrete Legendre maps, the choice of a point sphere complex reveals a 2-parameter family of enveloping circular principal contact element nets. The underlying circular nets are called the point sphere envelopes in \(\langle p \rangle^\perp\) (see Fig. 5).

Note that a Lie inversion \(\sigma_a\) is a Möbius transformation, that is, it maps point spheres onto point spheres, if and only if \(\langle a, p \rangle = 0\). Therefore, generically, the Lie inversions \(\sigma^{(1)}\) and \(\sigma^{(2)}\) that map adjacent enveloping contact elements onto each other, do not transport point spheres along the discrete R-congruence.

However, for each edge there exists a Möbius transformation uniquely determined by data from the discrete R-congruence that relates point spheres of adjacent contact elements in the Ribaucour family:
Proposition 3.9 Let \( r : V \rightarrow \mathbb{P}(\mathcal{L}) \) be a discrete R-congruence. Then the Lie inversions \( \sigma_m \) with respect to the linear sphere complexes determined by

\[
m : \mathcal{E} \rightarrow \mathbb{R}^{4,2}, \quad m_{ij} = \langle p, r_j \rangle r_i - \langle p, r_i \rangle r_j
\]

are Möbius transformations and satisfy, for any edge \((ij)\),

\[
\sigma_{m_{ij}}(r_i) = r_j.
\]

Moreover, those Möbius transformations transport the contact elements of envelopes along the discrete R-congruence and map adjacent point spheres of the point sphere envelope onto each other.

3.2 Construction of discrete R-congruences

Discrete R-congruences can be constructed from two arbitrary initial curves of spheres defined on two intersecting coordinate lines \( I^{(1)} \) and \( I^{(2)} \) of a quadrilateral cell complex \( \mathcal{G} \) by the following iteration:

- fix two initial sphere curves \( c^{(1)} : \mathcal{V}^{(1)} \rightarrow \mathbb{P}(\mathcal{L}) \) and \( c^{(2)} : \mathcal{V}^{(2)} \rightarrow \mathbb{P}(\mathcal{L}) \) that intersect at one vertex
- choose for each face \((ijkl)\) that contains an edge \((ij)\) of the curve \( c^{(1)} \) a Lie inversion that maps the prescribed spheres \( c_i \) and \( c_j \) onto each other; for each face this amounts to the choice of a \( \lambda \in \mathbb{R} \):

\[
\eta_{ijkl}^{(1)} := c_i^{(1)} - \lambda c_j^{(1)}
\]

- starting at a face \((ijkl)\) with three prescribed spheres \( c_i^{(1)}, c_j^{(1)} \) and \( c_l^{(2)} \), we complete the face by defining

\[
\tau_k := \sigma_{\eta_{ijkl}^{(1)}}(c_l^{(2)})
\]

- iteratively this procedure gives a coordinate ribbon of a discrete R-congruence including the spheres of the curve \( c^{(1)} \) and two spheres of the curve \( c^{(2)} \)
- to obtain the next coordinate ribbon we choose again suitable Lie inversions along the just constructed sphere curve and proceed as described above.

Conversely, given a nowhere umbilic discrete Legendre map \( f : \mathcal{V} \rightarrow \mathbb{P}(\mathbb{R}^{4,2}) \), that is, opposite curvature spheres do not coincide, then any choice of spheres in the contact elements along two intersecting coordinate lines uniquely determines a discrete R-congruence.

This construction relies on the following simple observation and is another instance of the interplay between line congruences and Q-nets as studied in [5,21]:

Fig. 5 A discrete R-congruence with various envelopes (plotted as circular quadrilaterals) of the Ribaucour family
Lemma 3.10  Given four contact elements \((f_i, f_j, f_k, f_l)\) of an elementary quadrilateral of a nowhere umbilic discrete Legendre map and three spheres \(r_i \in f_i, r_j \in f_j\) and \(r_l \in f_l\), then there exists a unique sphere \(r_k \in f_k\) such that \((r_i, r_j, r_k, r_l)\) provides a quadrilateral of a discrete \(R\)-congruence.

Proof  By Lemma 2.3, there exists a unique Lie inversion \(\sigma\) satisfying

\[
\sigma(r_i) = r_l \quad \text{and} \quad \sigma(s_{ij}) = s_{kl}.
\]

Then, \(r_k := \sigma(r_j) \in \text{span}\{s_{jk}, s_{kl}\}\) provides the sought-after sphere that completes the elementary quadrilateral of a discrete \(R\)-congruence.

3.3 Special discrete \(R\)-congruences

In this subsection we take up some recent ideas on discrete nets and special discrete Ribaucour transformations and briefly sketch how they fit into the framework developed in this work.

Circular nets. It is a well-known fact that for any circular net there exists a 2-parameter family of associated discrete Legendre maps.

We point out that a circular net can be understood as a special discrete \(R\)-congruence, where all \(R\)-spheres, namely the point spheres, lie in the fixed hyperbolic linear sphere complex determined by the point sphere complex \(\langle p \rangle^\perp\). Then the associated discrete Legendre maps provide the Ribaucour family of this sphere congruence.

Discrete Ribaucour coordinates. Discrete \(R\)-congruences consisting of spheres that lie in a fixed parabolic or elliptic linear sphere complex \(\langle a \rangle^\perp\) lead to particular Ribaucour families: for any choice of point sphere complex, there exists an envelope with point spheres lying on a sphere; namely, the sphere related to the fixed linear sphere complex \(\langle a \rangle^\perp\). These envelopes are then discrete Ribaucour coordinates as discussed in [9, Theorem 3.9].

Discrete isothermic \(R\)-congruences. A discrete \(Q\)-net in the Lie quadric \(\mathbb{P}(L)\) is called isothermic if any diagonal vertex star of the \(Q\)-net lies in a projective 3-dimensional subspace of \(\mathbb{P}(\mathbb{R}^4,2)\) that does not contain the four outer spheres of the vertex star. In particular, in the realm of discrete \(\Omega\)-nets [7,10], that is, discrete Legendre maps spanned by two isothermic sphere congruences, those \(Q\)-nets are intensively used.

Their characterization in terms of the existence of a Moutard lift (see [4,7,10]), immediately reveals a relation to the framework considered in this work:

Definition 3.11  A lift \(\mu : \mathcal{V} \to \mathcal{L} \subset \mathbb{R}^{4,2}\) of a discrete \(Q\)-net \(s : \mathcal{V} \to \mathbb{P}(L)\) is called a Moutard lift if opposite diagonals are parallel, that is,

\[
\delta\mu_{ik} \parallel \delta\mu_{jl},
\]

where \(\delta\mu_{ik} := \mu_k - \mu_i\) and \(\delta\mu_{jl} := \mu_l - \mu_j\).

This special global choice of homogeneous coordinates of a Moutard lift gives rise to additional Lie inversions that diagonally swap the \(R\)-spheres on each quadrilateral:

Proposition 3.12  A lift \(\mu : \mathcal{V} \to \mathcal{L} \subset \mathbb{R}^{4,2}\) of a discrete \(R\)-congruence \(r : \mathcal{V} \to \mathbb{P}(L)\) is a Moutard lift if and only if for each quadrilateral the Lie inversion \(\sigma^\delta\) with respect to the linear sphere complex \(\langle \delta\mu_{ik} \rangle^\perp\) diagonally interchanges the \(R\)-spheres:

\[
\sigma^\delta(\mu_i) = \mu_k \quad \text{and} \quad \sigma^\delta(\mu_j) = \mu_l.
\]
The Lie inversion \( \sigma_{\delta} \) related to a Moutard lift interchanges opposite R-spheres \( r_i \leftrightarrow r_k \) and \( r_j \leftrightarrow r_l \), curvature spheres \( s_{ij} \leftrightarrow s_{kl} \) and \( s_{il} \leftrightarrow s_{jk} \), and the corresponding contact elements \( f_i \leftrightarrow f_k \) and \( f_j \leftrightarrow f_l \).

**Proof** Suppose that \( \mu \) is a Moutard lift, then the linear sphere complex is determined by

\[
\langle \delta \mu_{ik} \rangle = \langle \delta \mu_{jl} \rangle
\]

and we therefore obtain

\[
\sigma_{\delta}(\mu_i) = \mu_k \quad \text{and} \quad \sigma_{\delta}(\mu_j) = \mu_l.
\]

Conversely, if we have

\[
\mu_k = \mu_i - \frac{2\langle \mu_i, \delta \mu_{ik} \rangle}{\langle \delta \mu_{ik}, \delta \mu_{ik} \rangle} \delta \mu_{ik},
\]

\[
\mu_l = \mu_j - \frac{2\langle \mu_j, \delta \mu_{ik} \rangle}{\langle \delta \mu_{ik}, \delta \mu_{ik} \rangle} \delta \mu_{ik},
\]

it follows that \( \delta \mu_{ik} \parallel \delta \mu_{jl} \) and \( \mu \) is indeed a Moutard lift. \( \square \)

The interaction of these Lie inversions \( \sigma_{\delta} \) induced by a Moutard lift with the geometric data of the envelopes is illustrated in Fig. 6.

### 4 Ribaucour families

#### 4.1 Geometric properties of envelopes in the Ribaucour family

In the following paragraphs we discuss various special properties of the 2-parameter family of envelopes in the Ribaucour family of a discrete R-congruence.

**Curvature spheres in a Ribaucour family**

In Lemma 3.6 we saw that the Lie inversions \( \sigma^{(1)} \) and \( \sigma^{(2)} \) transport the contact elements of the envelopes along the discrete R-congruence. Since two adjacent contact elements share a common sphere, namely the curvature sphere, this sphere is fixed by the corresponding Lie inversion. Therefore, we obtain the following property for all curvature spheres in a Ribaucour family:

**Proposition 4.1** The curvature spheres of opposite edges of any envelope in a Ribaucour family lie in the same linear sphere complex.
Totally umbilic faces

If the four curvature spheres of a face of a discrete Legendre map coincide, the face is called *umbilic*. While in the smooth case umbilic points are rather special, in any \((2,1)-\text{Ribaucour family*} we obtain envelopes with umbilic faces:

**Lemma 4.2** Let \(f\) be a discrete Legendre map in a \((2,1)-\text{Ribaucour family*}. A face \((ijkl)\) of \(f\) is umbilic if and only if the four contact elements \(f_i, f_j, f_k\) and \(f_l\) are also contact elements of the Dupin cyclide generated by the R-spheres of this face.

In this case, for any projection to a Möbius geometry, the four point spheres of \(f\) lie on a curvature circle of the Dupin cyclide.

**Proof** Let \(f\) be a discrete Legendre map in a \((2,1)-\text{Ribaucour family* and assume that the contact elements} f_i, f_j, f_k\) and \(f_l\) of a face \((ijkl)\) coincide with contact elements of the Dupin cyclide \(d = D_1 \oplus_{\perp} D_2\), where the R-spheres \(r_i, r_j, r_k\) and \(r_l\) lie in the \((2,1)\)-plane \(D_1\). Then, \(f_i = \text{span}(r_i, s_i)\), where \(s_i \in D_2\). But, since \(s_i\) is also in oriented contact with the R-spheres \(r_j, r_k\) and \(r_l\), the sphere \(s_i\) is the constant curvature sphere of the envelope \(f\) at this face. Hence this face of \(f\) is umbilic.

Conversely, suppose that an envelope \(f\) of a discrete \((2,1)-\text{R-congruence* has a totally umbilic face, then the constant curvature sphere has to be in oriented contact with all four R-spheres of this face. Since these four R-spheres determine a Dupin cyclide, the constant curvature sphere of \(f\) is also a curvature sphere of this Dupin cyclide (in the other curvature sphere family than the R-spheres). This completes the proof. \(\Box\)

Recall that, by Corollary 3.7, any choice of an initial contact element at an initial vertex provides a unique envelope in the Ribaucour family. Therefore, with the help of Lemma 4.2, we can construct umbilic faces at any face of a discrete \((2,1)-\text{R-congruence*}:

**Corollary 4.3** For any face of a discrete \((2,1)-\text{R-congruence* there exists a 1-parameter family of envelopes in the Ribaucour family that are umbilic at this face.**

**Permutability theorems**

A key property in the theory of transformations is the existence of permutability theorems: given two Ribaucour transforms \(f_1\) and \(f_2\) of a Legendre map \(f\), then there exists a 1-parameter family of Legendre maps that are simultaneous transforms of \(f_1\) and \(f_2\). Moreover, corresponding points of these Legendre maps are concircular. This result, generically, holds for smooth, as well as, for discrete Legendre maps (cf. [4, Theorem 3.6], [8], [22, §8]).

However, contrary to the smooth case, for any discrete Legendre map circularity of corresponding points in the permutability theorem can fail: four envelopes in a Ribaucour family obviously satisfy the permutability theorem. But, if we project to a Möbius geometry, corresponding point spheres of the four envelopes do not have to lie on a circle. The point spheres lie on the corresponding R-sphere and are therefore in general only cospherical.

**Proposition 4.4** Let \(f\) be a discrete Legendre map, then there exist three Ribaucour transforms \(f_1, f_2\) and \(f_{12}\) of \(f\) such that \(f_{12}\) is a simultaneous Ribaucour transform of \(f_1\) and \(f_2\) and, for any projection to a Möbius geometry, corresponding point spheres of these four nets are not circular.
Two envelopes $f$ and $\hat{f}$ of the Ribaucour family (orange) can be interpolated with a 1-parameter family of envelopes (green) that are constructed from an initial curve $\gamma$ going through two initial contact elements of $f$ and $\hat{f}$. (Color figure online)

We emphasize that if corresponding contact elements of $f$, $f_1$, and $f_2$ span a 3-dimensional projective subspace of signature $(2, 2)$, then there only exists a 1-parameter family of simultaneous Ribaucour transforms $f_{12}$. The points of the contact elements will then be circular. Hence in this case, the usual permutability theorem holds.

We remark that the significant difference to the smooth transformation theory pointed out in Proposition 4.4 leads to examples of discrete nets that have no counterparts in the smooth surface theory (see for example [24, §1.1]).

Deformations of envelopes in the Ribaucour family

The ambiguity of envelopes in the Ribaucour family of a discrete R-congruence $r : V \to \mathbb{P}(\mathcal{L})$ provides a possibility to smoothly deform two envelopes $f$ and $\hat{f}$ into each other.

Let $r_0$ be an R-sphere of the congruence $r$ at an initial vertex $v_0 \in V$. Then, by Corollary 3.7, any choice of a smooth initial Legendre curve $\gamma_0 : [0, 1] \to Z$ with

\[
\gamma_0(0) = f_0 \text{ and } \gamma_0(1) = \hat{f}_0
\]

gives rise to a 1-parameter family $\{f^{\gamma_0(t)}\}_{t \in [0, 1]}$ of envelopes in the Ribaucour family (see Fig. 7).

In particular, this construction yields a smooth Legendre curve $t \mapsto f^{\gamma_0(t)}_v$ for each vertex $v \in V$ that lies in the fixed parabolic linear sphere complex determined by the corresponding R-sphere $r_v$. Moreover, according to Lemma 3.6, two adjacent Legendre curves are related by a Lie inversion. Thus, they envelop a 1-parameter family of spheres and form a smooth Ribaucour pair of curves.

If projecting to a Möbius geometry, the point sphere envelopes of $\{f^{\gamma_0(t)}\}_{t \in [0, 1]}$ provide smooth deformations of circular nets, where the vertices move along spherical curves. In particular, if the initial curve $\gamma_0$ is a (part of a) circle, then circularity of it is preserved along the entire discrete R-congruence (cf. Proposition 3.9).

The construction pointed out in this section provides a way of obtaining discrete and semi-discrete triply orthogonal systems with special vertical coordinate surfaces having one family of spherical curvature lines. For particular choices of the initial curve $\gamma_0$ we even obtain semi-discrete cyclic systems. A deeper analysis of these systems will be given in a future work.
4.2 Discrete Ribaucour pairs in the Ribaucour family

To gain further geometric insights into the Ribaucour family of a discrete R-congruence, in this subsection, we fix two envelopes of a discrete R-congruence, classically called a Ribaucour pair of discrete Legendre maps. The contact elements of a Ribaucour pair form a fundamental line system in the sense of [5,21] since R-congruences are Q-nets.

Thus, suppose that \( f, \hat{f} : V \to \mathbb{Z} \) are two discrete Legendre maps enveloping the discrete R-congruence \( r : V \to \mathbb{P}(L) \). Then, for any edge \((ij)\) the contact elements \((fi, fj, \hat{f}j, \hat{f}i)\) provide a quadrilateral of a discrete Legendre map, that is, adjacent contact elements share a common sphere. Thus, along each coordinate line of a Ribaucour pair the contact elements of \( f \) and \( \hat{f} \) yield a coordinate ribbon of a discrete Legendre map; these coordinate ribbons will be called vertical ribbons of the Ribaucour pair. The “curvature spheres” of the vertical ribbons are given by the R-spheres and the curvature spheres of \( f \) and \( \hat{f} \) along the corresponding coordinate line of the Ribaucour pair. Moreover, note that any two consecutive vertical ribbons also form a Ribaucour pair enveloping curvature spheres of \( f \) and \( \hat{f} \).

In the following paragraphs we demonstrate how the structures of the various Ribaucour pairs interact with each other.

**Proposition 4.5** Let \( f, \hat{f} : V \to \mathbb{Z} \) be two envelopes of a discrete R-congruence. Then there exists a map

\[
n^{(3)} : \mathcal{F} \to \mathbb{P}(\mathbb{P}^{4,2}) \backslash \mathbb{P}(\mathcal{L})
\]

such that for any quadrilateral \((ijkl)\) the induced Lie inversion \( \sigma^{(3)} := \sigma_{n^{(3)}} \) interchanges the curvature spheres of \( f \) and \( \hat{f} \),

\[
\sigma^{(3)}(s_{ij}) = \hat{s}_{ij}, \quad \sigma^{(3)}(s_{jk}) = \hat{s}_{jk}, \quad \sigma^{(3)}(s_{kl}) = \hat{s}_{kl}, \quad \sigma^{(3)}(s_{il}) = \hat{s}_{il}.
\]

Moreover, for any quadrilateral the Lie inversion \( \sigma^{(3)} \) preserves the R-spheres, maps corresponding contact elements of the Ribaucour pair \((f, \hat{f})\) onto each other and is involutive to \( \sigma^{(1)} \) and \( \sigma^{(2)} \) (see Fig. 8 for notation).

**Proof** Firstly observe that, since \( s_{kl} = \sigma^{(2)}(s_{ij}) \) and \( \hat{s}_{kl} = \sigma^{(2)}(\hat{s}_{ij}) \), we can choose homogeneous coordinates such that

\[
0 = s_{ij} - \hat{s}_{ij} - s_{kl} + \hat{s}_{kl},
\]

as well as homogeneous coordinates

\[
0 = s_{jk} - \hat{s}_{jk} - s_{il} + \hat{s}_{il}
\]

for the other four curvature spheres. Moreover, we define two vectors \( n^{(3)} \) and \( \tilde{n}^{(3)} \) by

\[
n^{(3)} := s_{ij} - \hat{s}_{ij} = s_{kl} - \hat{s}_{kl},
\]

\[
\tilde{n}^{(3)} := s_{il} - \hat{s}_{il} = s_{jk} - \hat{s}_{jk}.
\]

Then, the R-spheres \( r_i, r_j, r_k \) and \( r_l \) lie in the induced linear sphere complexes \( n^{(3)} \) and \( \tilde{n}^{(3)} \), which are therefore involutive to \( n^{(1)} \) and \( n^{(2)} \).

Furthermore, since

\[
s_{il} = \langle s_{ij}, n^{(2)} \rangle r_i - \langle r_i, n^{(2)} \rangle s_{ij},
\]

\[
\hat{s}_{il} = \langle \hat{s}_{ij}, n^{(2)} \rangle r_i - \langle r_i, n^{(2)} \rangle \hat{s}_{ij},
\]

\( \text{Springer} \)
Two envelopes \(f\) and \(\hat{f}\) of a discrete R-congruence define a linear sphere complex \(n^{(3)}\) and the corresponding Lie inversion \(\sigma^{(3)}\). The Lie inversion interchanges curvature spheres and contact elements of the two envelopes while fixing the R-spheres of the congruence.

The two linear sphere complexes induced by \(n^{(3)}\) and \(\tilde{n}^{(3)}\) coincide:
\[
\tilde{n}^{(3)} = \langle n^{(2)}, n^{(3)} \rangle r_i - \langle n^{(2)}, r_i \rangle n^{(3)} = -\langle n^{(2)}, r_i \rangle n^{(3)}.
\]

Thus, on each hexahedron of a Ribaucour pair \((f, \hat{f})\) we obtain the following symmetric configuration of the curvature spheres and the R-spheres:
\[
s_i^{(1)}, s_{kl}^{(1)}, s_{ij}^{(1)} \perp n^{(1)}, s_j^{(2)}, s_{il}^{(2)}, s_{jl}^{(2)} \perp n^{(2)}, r_i, r_j, r_k, r_l \perp n^{(3)}. \tag{6}
\]

In particular, for \(\nu = 1, 2, 3\), the Lie inversion \(\sigma^{(\nu)}\) fixes the four spheres assigned to the \((\nu)\)-edges and interchanges the spheres within the other two linear sphere complexes.

Thus, the Lie inversions \(\sigma^{(3)}\) given in Proposition 4.5 reveal a crucial property between two envelopes of a discrete R-congruence:

**Theorem 4.6** Two envelopes of a discrete R-congruence are related by a facewise constant Lie inversion.

Furthermore, as a consequence of Lemma 2.4, the Lie inversions \(\sigma^{(3)}\) constructed in Proposition 4.5 induce pairings in the entire Ribaucour family:

**Corollary 4.7** Let \((f, \hat{f})\) be a discrete Ribaucour pair of a discrete R-congruence. Then the corresponding Lie inversions \(\sigma^{(3)}\) decompose the Ribaucour family into discrete Ribaucour pairs.

We emphasize that the Lie inversions \(\sigma^{(3)}\) and the induced decomposition of the Ribaucour family depend on the initial choice of the Ribaucour pair \((f, \hat{f})\). Hence, the decomposition given in Corollary 4.7 is not unique.

### 4.3 Cyclidic nets in the Ribaucour family

For any face of a discrete Legendre map there exists a 1-parameter family of *face-cyclides*, Dupin cyclides that share the four curvature spheres assigned to a face with the discrete Legendre map (cf. [3,24]). Note that any face-cyclide has four distinguished curvature lines,
namely the curvature lines that join two adjacent contact elements of the discrete Legendre map and lie on the corresponding curvature sphere. We will denote the space of \((2, 1)\)-planes in \(\mathbb{R}^{4,2}\) by \(G_{(2,1)}(\mathbb{R}^{4,2})\) and Dupin cyclides by two complementary \((2, 1)\)-planes \(D^{(1)}\) and \(D^{(2)}\) with \(D^{(1)} \oplus D^{(2)} = \mathbb{R}^{4,2}\).

To begin with, we shall point out how the Lie inversions \(\sigma^{(1)}\) and \(\sigma^{(2)}\) corresponding to a discrete \(R\)-congruence interact with the face-cyclides of its envelopes.

**Lemma 4.8** A congruence of face-cyclides of an envelope is preserved by the Lie inversions \(\sigma^{(1)}\) and \(\sigma^{(2)}\), however, the contact elements of opposite curvature lines going through the vertices of the discrete Legendre map are interchanged by the corresponding Lie inversion.

**Proof** Let \(d = D^{(1)} \oplus D^{(2)}\) be a face-cyclide of the face \((ijkl)\) with \(s_{ij}, s_{kl} \in D^{(1)}\) and \(s_{il}, s_{jk} \in D^{(2)}\). Moreover, let \(\tilde{s} \in D^{(1)}\) be a curvature sphere of the face-cyclide. Then \(\langle \tilde{s}, s_{il} \rangle = \langle \tilde{s}, s_{jk} \rangle = 0\) and we conclude that \(\tilde{s} \perp n^{(1)}\). Thus, the spheres in \(D^{(1)}\) are fixed by the Lie inversion \(\sigma^{(1)}\) and, therefore, also the face-cyclide as unparametrized surface.

Furthermore, any contact element along the curvature line going through \(f_i\) and \(f_i\) is given by \(\langle s_{il}, \tilde{s} \rangle\) for a sphere \(\tilde{s} \in D^{(1)}\). Since

\[
\sigma^{(1)}(s_{il}) = s_{jk} \quad \text{and} \quad \sigma^{(1)}(\tilde{s}) = \tilde{s},
\]

these contact elements are mapped to the contact elements of the opposite curvature line of the face-cyclide. Analogous arguments for the other pair of curvature lines complete the proof. \(\square\)

This lemma also provides a construction for a special congruence

\[
d: \mathcal{F} \rightarrow G_{(2,1)}(\mathbb{R}^{4,2}) \times G_{(2,1)}(\mathbb{R}^{4,2})
\]

of face-cyclides for \(f\) from a given face-cyclide \(d_a = D_a^{(1)} \oplus D_a^{(2)}\) of an initial face \((ij^j'i')\) (for notations see Fig. 9): let

\[
D_\beta^{(1)} := (s_{jj'j} \oplus D_a^{(1)}) \cap (n_\beta^{(1)})^\perp \quad \text{and} \quad D_\beta^{(2)} := (D_\beta^{(1)})^\perp,
\]

then \(d_\beta = D_\beta^{(1)} \oplus D_\beta^{(2)}\) is a face-cyclide for the face \((jkk'j')\). Furthermore, defining

\[
D_\gamma^{(2)} := (s_{jj'k'} \oplus D_\beta^{(2)}) \cap (n_\gamma^{(2)})^\perp, \\
D_\delta^{(1)} := (s_{jj''k'} \oplus D_\gamma^{(1)}) \cap (n_\delta^{(1)})^\perp,
\]

yields unique face-cyclides \(d_\gamma\) and \(d_\delta\) for the four faces of the vertex-star. This construction consistently extends on all faces and provides a face-cyclide congruence for the discrete Legendre map.

Projecting to any Möbius geometry \(\langle p \rangle^\perp\), reveals a remarkable property of the just constructed face-cyclide congruence \(d\).

Firstly, observe that the face-cyclides \(d_a\) and \(d_\beta\) share a common curvature line \(c_{a\beta}\), namely the circle of point spheres joining the point spheres \(p_j \in f_j\) and \(p_{j'} \in f_{j'}\). The contact elements along \(c_{a\beta}\) coincide due to Eq. (7), and hence the two face-cyclides define a piecewise smooth surface that is \(C^1\) across the common curvature line.

In the same way the pairs \([d_\beta, d_\gamma]\) and \([d_\gamma, d_\delta]\) meet at a common circular curvature line \(c_{\beta\gamma}\) and \(c_{\gamma\delta}\), respectively. Note that the circles \(c_{a\beta}\) and \(c_{\beta\gamma}\), as well as \(c_{\beta\gamma}\) and \(c_{\gamma\delta}\), intersect orthogonally. Therefore, since the circular curvature lines \(c_{a\beta}, c_{\beta\gamma}\) and \(c_{\gamma\delta}\) of the face-cyclides around the vertex-star go through the common contact element \(f_{j'}\), also the face-cyclides \(d_\delta\) and \(d_\alpha\) meet at a common curvature line \(c_{\delta\alpha}\). Since all contact elements of
Fig. 9 Notation used for face cyclides on four quadrilaterals at a common vertex

$d_\delta$ and $d_\alpha$ along the common circular curvature line $c_{\delta\alpha}$ contain the curvature sphere $s_{ij}$ of $f$, also the contact elements of $d_\delta$ and $d_\alpha$ along $c_{\delta\alpha}$ coincide.

Thus, with the help of the Lie inversions $\sigma^{(1)}$ and $\sigma^{(2)}$, we have constructed a particular face-cyclide congruence, discussed in [2,3]:

**Definition 4.9** Let $f : V \rightarrow Z$ be a discrete Legendre map, then a cyclidic net of $f$ is a congruence of face-cyclides $d : F \rightarrow G_{(2,1)}(\mathbb{R}^4,2) \times G_{(2,1)}(\mathbb{R}^4,2)$ such that two face-cyclides adjacent along the edge $(ij)$ share the same contact elements along the curvature direction going through $f_i$ and $f_j$.

The symmetries described in (6) can be exploited to relate cyclidic nets of a Ribaucour pair:

**Theorem 4.10** Let $(f, \hat{f})$ be a discrete Ribaucour pair related by the facewise constant Lie inversion $\sigma^{(3)}$. If $d = (D^{(1)}, D^{(2)}) : F \rightarrow G_{(2,1)}(\mathbb{R}^4,2) \times G_{(2,1)}(\mathbb{R}^4,2)$ is a cyclidic net of $f$, then

$$\hat{d} : F \rightarrow G_{(2,1)}(\mathbb{R}^4,2) \times G_{(2,1)}(\mathbb{R}^4,2), \quad \hat{d} = (\sigma^{(3)}(D^{(1)}), \sigma^{(3)}(D^{(2)}))$$

provides a cyclidic net for $\hat{f}$.

**Proof** Since corresponding curvature spheres of $f$ and $\hat{f}$ are mapped onto each other by the Lie inversions $\sigma^{(3)}$ and Dupin cyclides are invariant under Lie inversions, $d_{ijkl}$ defines a face-cyclide for the face $(ijkl)$ of $\hat{f}$.

Moreover, to prove that $\hat{d}$ indeed provides a cyclidic net of $\hat{f}$, we consider two adjacent faces along an edge $(ij)$: firstly, observe that the Lie inversions $\sigma_n^{(3)}$ and $\sigma_{\bar{n}}^{(3)}$ belonging to the two adjacent faces are determined by the two linear sphere complexes

$$n^{(3)} := s_{ij} - \lambda \hat{s}_{ij} \quad \text{and} \quad \bar{n}^{(3)} := s_{ij} - \bar{\lambda} \hat{s}_{ij},$$

where $s_{ij} \in s_{ij}, \hat{s}_{ij} \in \hat{s}_{ij}$ and $\lambda, \bar{\lambda} \in \mathbb{R}$ are appropriately chosen. Thus, by Lemma 2.2(iii), the contact elements of the face-cyclides of $f$ along the common curvature line passing through $f_i$ and $f_j$ are mapped to the same contact elements by $\sigma_n^{(3)}$ and $\sigma_{\bar{n}}^{(3)}$. Thus, two adjacent face-cyclides of $\hat{d}$ share common contact elements along the curvature line through $\hat{f}_i$ and $\hat{f}_j$.

In [27, Definition 4.4], the existence of two special Dupin cyclide congruences for a smooth Ribaucour pair of Legendre maps was pointed out. We report on a similar construction in the discrete case:
Definition 4.11 Let \( f, \hat{f} : \mathcal{V} \to \mathcal{Z} \) be two envelopes of a discrete R-congruence. Face-cyclides along a vertical ribbon will be called \( R \)-cyclides of the Ribaucour pair \( (f, \hat{f}) \), that is, for a vertical face, a Dupin cyclide \( \delta = R \oplus \perp \tilde{R} \subseteq \mathbb{R}^{4,2} \) satisfying

\[
\mathcal{s}_{ij}, \hat{\mathcal{s}}_{ij} \in R \quad \text{and} \quad \mathcal{v}_i, \hat{\mathcal{v}}_j \in \tilde{R}.
\]

In Theorem 4.10, we have learned that cyclidic nets for a Ribaucour pair arise in distinguished pairs, where the face-cyclides are related by the Lie inversions \( \sigma(3) \). For these cyclidic nets there exists a canonical choice for the \( R \)-cyclides on the vertical ribbons:

Corollary 4.12 Suppose that \( d \) and \( \hat{d} \) are cyclidic nets of a Ribaucour pair \( (f, \hat{f}) \) related by the Lie inversions \( \sigma(3) \). Then for an edge \((ij)\) of the Ribaucour pair, the contact elements along two corresponding curvature lines of \( d \) and \( \hat{d} \) passing through \( f_i \) and \( f_j \), as well as \( \hat{f}_i \) and \( \hat{f}_j \), uniquely determine an \( R \)-cyclide for the corresponding vertical face.

Proof Since the contact elements along the curvature lines under consideration are related by the Lie inversion \( \sigma(3) \), two corresponding contact elements share a common sphere lying in \((n(3))^{\perp}\). In this way, we obtain a 1-parameter family of spheres that are in oriented contact with the spheres \( \mathcal{s}_{ij} \) and \( \hat{\mathcal{s}}_{ij} \) and are therefore curvature spheres of a face-cyclide for the vertical face. \( \square \)

We deduce that, by construction, the induced \( R \)-cyclides investigated in Corollary 4.12 provide (one ribbon of) a cyclidic net along each vertical ribbon. However, observe that two adjacent induced \( R \)-cyclides belonging to two vertical ribbons from different coordinate directions do not share a common curvature line. In particular, these Dupin cyclides do not give a 3D cyclidic net as introduced in [3, Section 3.2].

5 Envelopes with spherical curvature lines

In this section, we will draw attention to the Ribaucour transformation of discrete channel surfaces as discussed in [24] and the wider class of discrete Legendre maps with a family of spherical curvature lines.

5.1 Discrete spherical curvature lines

Inspired by the classification of spherical curvature lines in the smooth case (see [1,14]), we introduce the notion of osculating complexes for discrete Legendre maps. To obtain uniqueness of the osculating complexes, we suppose a mild genericity condition on the discrete Legendre map. Note that also in the smooth case, uniqueness fails for the class of channel surfaces.

Thus, let \( f : \mathcal{V} \to \mathcal{Z} \) be a discrete Legendre map and fix a point sphere complex \( p \in \mathbb{R}^{4,2}, \langle p, p \rangle < 0 \). Furthermore, suppose that four consecutive contact elements \( f_{i'}, f_i, f_j \) and \( f_{j'} \) along a coordinate line are nowhere circular, that is, the four point spheres \( p_{i'}, p_i, p_j \) and \( p_{j'} \) do not lie on a circle.

Then the spheres of these four contact elements lie in a unique elliptic linear sphere complex: let \( \mathcal{s} \) and \( \hat{\mathcal{s}} \) be the two oriented spheres that contain the four point spheres \( p_{i'}, p_i, p_j \) and \( p_{j'} \). Then the sought-after linear sphere complex is given by

\[
\mathcal{t} := \langle \hat{\mathcal{s}}, \mathcal{s}_{ij} \rangle \mathcal{s} - \langle \mathcal{s}, \mathcal{s}_{ij} \rangle \hat{\mathcal{s}},
\]
where $s_{ij}$ denotes the curvature sphere belonging to the edge $(ij)$. Clearly, the spheres of the contact elements $f_i := \text{span}\{s_{ij}, p_i\}$ and $f_j := \text{span}\{s_{ij}, p_j\}$ lie in $t^\perp$. Moreover, since $s_{ii}' \in f_i$ and $s_{jj}' \in f_j$, also the spheres of the contact elements

$$f_i' = \text{span}\{s_{ii}', p_i\} \quad \text{and} \quad f_j' = \text{span}\{s_{jj}', p_j\}$$

are contained in $t^\perp$.

**Definition 5.1** Let $f : \mathcal{V} \rightarrow \mathcal{Z}$ be a nowhere circular discrete Legendre map, then

$$t : \mathcal{E} \rightarrow \mathbb{P}(\mathbb{R}^{4,2}), \quad (ij) \mapsto t_{ij} := \text{span}\{f_i', f_i, f_j, f_j'\}^\perp$$

are called the osculating complexes of $f$.

As an immediate consequence of the above considerations, we can characterize spherical curvature lines of a discrete Legendre map:

**Proposition 5.2** The $(1)$-coordinate lines of a nowhere circular discrete Legendre map are spherical if and only if the osculating complexes along each $(1)$-coordinate line are constant.

### 5.2 Ribaucour transformations of discrete channel surfaces

Curvature spheres of discrete channel surfaces are constant in the circular direction and hence the corresponding contact elements along the circular parameter lines lie in a parabolic linear sphere complex. We observe the following property if the spheres of an R-congruence lie in a parabolic subcomplex:

**Proposition 5.3** A discrete R-congruence admits an envelope with constant curvature spheres along each $(1)$-coordinate line if and only if along each $(1)$-coordinate line the R-spheres lie in a parabolic complex and the map $n^{(2)}$ is constant along each $(1)$-coordinate ribbon.

**Proof** Suppose that $r : \mathcal{V} \rightarrow \mathbb{P}(\mathcal{L})$ is a discrete R-congruence admitting an envelope with a constant curvature sphere along each $(1)$-coordinate line. Then, along each such coordinate line the constant curvature sphere and the R-spheres are in oriented contact and therefore lie in a fixed parabolic linear sphere complex.

Furthermore, let us consider a $(1)$-coordinate ribbon bounded by two $(1)$-coordinate lines $\gamma_i$ and $\gamma_{i+1}$. Moreover, without loss of generality, we choose homogeneous coordinates such that the induced Lie inversions $\sigma^{(2)}_{\alpha}$ and $\sigma^{(2)}_{\beta}$ of two faces adjacent along the edge $(jk)$ of the coordinate ribbon are given by

$$n^{(2)}_{\alpha} := t_j - t_k \quad \text{and} \quad n^{(2)}_{\beta} := t_j - \lambda_\beta t_k,$$

where $\lambda_\beta \in \mathbb{R}\setminus\{0\}$ is a suitable constant.

Then, denoting the constant curvature spheres along the coordinate line $\gamma_i$ by $s_i^{(1)}$, we conclude that the spheres given by $\sigma^{(2)}_{n_\alpha}(s_i^{(1)})$ and $\sigma^{(2)}_{n_\beta}(s_i^{(1)})$ have to coincide. Hence, there exists a constant $c \in \mathbb{R}\setminus\{0\}$ such that

$$0 = \sigma^{(2)}_{n_\alpha}(s_i^{(1)}) - c\sigma^{(2)}_{n_\beta}(s_i^{(1)})$$

$$= (1 - c)s_i^{(1)} + (1 - c\lambda_\beta)\frac{\langle s_i^{(1)}, t_k \rangle}{\langle t_k, t_j \rangle}t_k + (c - 1)\frac{\langle s_i^{(1)}, t_k \rangle}{\langle t_k, t_j \rangle}t_j.$$
Therefore, since $r_j, r_k$ and $s_j^{(1)}$ are linearly independent, each scalar factor has to vanish and we conclude that $n_j^{(2)}(s) = n_k^{(2)}(s)$. So it is constant along each (1)-coordinate ribbon. Geometrically, the constant $n^{(2)}$ is the intersection of the lines $\langle s_j^{(1)}, s_{j+1}^{(1)} \rangle$ and $\langle r_j, r_k \rangle$.

Conversely, assume that along each (1)-coordinate line the R-spheres lie in a fixed parabolic complex. Then, in particular, along each (1)-coordinate line all R-spheres are in oriented contact with the constant curvature sphere along this coordinate line. Furthermore, since the map $n^{(2)}$ is constant along each (1)-coordinate ribbon, the choice of an initial contact element containing the corresponding constant curvature sphere reveals the sought-after envelope of the R-congruence (cf. Lemma 3.6).

We recall that a discrete Legendre map is a discrete channel surface in the sense of Hertrich-Jeromin et al. [24], if it admits a face-cyclide congruence which is constant along one family of coordinate ribbons.

In particular, discrete channel surfaces can be characterized by special properties of their curvature sphere congruences [24, Proposition 2.4]: a discrete Legendre map is a discrete channel surface with circular (1)-direction if and only if the curvature sphere congruence $s^{(1)}$ is constant along any (1)-coordinate line and the curvature spheres $s^{(2)}$ determine a fixed (2, 1)-plane along each (1)-coordinate ribbon.

**Theorem 5.4** A discrete R-congruence is enveloped by two discrete channel surfaces with circular (1)-direction if and only if the map $n^{(2)}$ is constant along each (1)-coordinate ribbon and the R-spheres along each (1)-coordinate line are curvature spheres of a Dupin cyclide.

**Proof** Let $r : \mathcal{V} \rightarrow \mathbb{P}(\mathcal{L})$ be a discrete R-congruence enveloped by two discrete channel surfaces $f$ and $\hat{f}$ with circular (1)-direction. Then, by Proposition 5.3, the map $n^{(2)}$ is constant along each (1)-coordinate ribbon.

To prove the second property of the discrete R-congruence, let us consider a (1)-coordinate ribbon and denote the constant curvature spheres of $f$ and $\hat{f}$ along the two boundary (1)-coordinate lines by $s_i, s_{i+1}, \hat{s}_i$ and $\hat{s}_{i+1}$, respectively. Furthermore, by Hertrich-Jeromin et al. [24, Proposition 2.4], the other family of curvature spheres of $f$ along this (1)-coordinate ribbon lies in a $(2, 1)$-plane $D_i$.

Defining the projection onto $\langle \hat{s}_i \rangle^\perp$

\[
\pi(\tau) = \tau - \frac{\langle \tau, \hat{s}_i \rangle}{\langle \hat{s}_i, \hat{s}_i \rangle} \hat{s}_i,
\]

we deduce that all R-spheres along the (1)-coordinate line lie in the $(2, 1)$-plane $\pi(D_i)$. Therefore, the R-spheres are curvature spheres of a Dupin cyclide.

Conversely, suppose that the R-spheres along a (1)-coordinate line $r_{l_0}$ are curvature spheres of a Dupin cyclide, that is, they lie in a $(2, 1)$-plane $C_{l_0}$. Then, any choice of two initial contact elements $f_0 := \text{span}\{r_{l_0}, s_{l_0}\}$ and $\hat{f}_0 := \text{span}\{r_{l_0}, \hat{s}_{l_0}\}$, where $s_{l_0}, \hat{s}_{l_0} \in C_{l_0}^\perp$ provides two enveloping discrete channel surfaces.

As an immediate consequence of the 1-parameter freedom in the choice of the initial contact element $f_0$ in the proof of Theorem 5.4, we obtain the following corollary:

**Corollary 5.5** If a discrete R-congruence admits two discrete channel surfaces as envelopes, then there exists a 1-parameter family of enveloping discrete channel surfaces.

Furthermore, we remark that Theorem 5.4 reveals how the constructions given in Sect. 3.2 yield discrete R-congruences admitting a 1-parameter family of discrete channel surfaces in their Ribaucour families.
In particular, suppose that a discrete R-congruence consists of point spheres and satisfies the conditions of Theorem 5.4. Geometrically, those discrete R-congruences are provided by circular nets where the point spheres of one family of coordinate lines lie on circles such that two adjacent ones are related by a Möbius inversion. Then, by Corollary 5.5, there exists a 1-parameter choice of contact elements such that the constructed principal net provides a discrete channel surface, that is, the principal net has indeed a constant curvature sphere along each coordinate line of one family (for details see also [24]).

Using the R-cyclides of a discrete Ribaucour pair given in Definition 4.11, we observe that the geometric structure of two enveloping discrete channel surfaces is also reflected in the geometry of the vertical faces of the Ribaucour pair:

**Corollary 5.6** A Ribaucour pair consists of two discrete channel surfaces with circular (1)-direction if and only if along each vertical (1)-coordinate ribbon there exists a constant R-cyclide.

**Proof** Suppose that a discrete R-congruence is enveloped by two discrete channel surfaces \( f \) and \( \hat{f} \) with circular (1)-direction. Then the contact elements of each (1)-vertical coordinate ribbon provide a coordinate ribbon of a discrete channel surface: according to Theorem 5.4, the curvature spheres along the vertical ribbon, namely the R-spheres, lie in a \((2, 1)\)-plane. Furthermore, the other curvature spheres of the vertical Legendre map, given by the curvature spheres of \( f \) and \( \hat{f} \), are constant (cf. [24, Proposition 2.4])

Hence, since the (1)-vertical Legendre maps are discrete channel surfaces, there exists a constant face-cyclide along each of these coordinate ribbons, which is then by definition also an R-cyclide of the Ribaucour pair \((f, \hat{f})\).

Conversely, if along each (1)-vertical ribbon there exists a constant R-cyclide, the R-spheres along each ribbon lie in a fixed \((2, 1)\)-plane and, by Proposition 5.3, the map \( n^{(1)} \) is constant along each (1)-coordinate ribbon of the Ribaucour pair. Thus, the claim follows from Theorem 5.4.

To conclude this section we remark on a general property of Ribaucour transforms of discrete channel surfaces. This also gives insights into the geometry of the other envelopes of a Ribaucour family containing a 1-parameter family of discrete channel surfaces.

**Proposition 5.7** The Ribaucour transforms of a discrete channel surface have a family of discrete spherical curvature lines.

**Proof** Let \( f \) be a discrete channel surface with circular (1)-direction and denote by \( r \) a discrete R-congruence of \( f \). Contemplate a (1)-coordinate line with an adjacent coordinate ribbon: we denote by \( s_i^{(1)} \) the constant curvature sphere of \( f \) and by \( D_{ij}^{(2)} \) the \((2, 1)\)-plane containing the curvature spheres of the other curvature sphere congruence along the coordinate ribbon. Then, the contact elements of \( f \) along this coordinate line lie in the 3-dimensional space \( s_i^{(1)} \oplus D_{ij}^{(2)} \). Hence, in particular, the R-spheres of the discrete R-congruence along this coordinate line, as well as the elements \( n^{(1)} \) along the coordinate ribbon, lie in this space.

Therefore, the contact elements along each (1)-coordinate line of any envelope of \( r \) lie in a fixed linear sphere complex and, by Proposition 5.2, we indeed obtain an envelope with a family of spherical curvature lines.
