(Dated: November 28, 2011)

We investigate the properties of the semiclassical short periodic orbit approach for the study of open quantum maps that was recently introduced in [M. Novaes, J.M. Pedrosa, D. Wisniacki, G.G. Carlo, and J.P. Keating, Phys. Rev. E 80, 035202(R) 2009]. We provide conclusive numerical evidence, for the paradigmatic systems of the open baker and cat maps, that by using this approach the dimensionality of the eigenvalue problem is reduced according to the fractal Weyl law. The method also reproduces the projectors $|\psi^R_n(\chi)\rangle\langle\psi^L_n(\chi)|$, which involves the right and left states associated with a given eigenvalue and is supported on the classical phase space repeller.

PACS numbers: 05.45.Pq

I. INTRODUCTION

One of the cornerstones of the semiclassical approach to quantum mechanics is the Gutzwiller trace formula, which relates the fluctuating part of the quantum density of states to the classical periodic orbits of a chaotic system [1]. However, this relation requires infinitely long orbits and involves divergent sums. More recently, periodic orbits have been used to study quantum spectra in a different way, by constructing some special quantum states, called scar functions, which are adapted to the classical periodic orbits and involve divergent sums. They are related by a discrete Fourier transform, i.e. $\langle p|\psi_J(\chi)\rangle = \frac{1}{\sqrt{N}} e^{-2i\pi j\chi}\langle k|\psi_k(\chi)\rangle$.

The scattering analog of the short periodic orbit approach has been introduced in [2]. Scar functions were used to study quantum spectra in several systems [3–9]. One the other hand, the (right) orbit approach has been introduced in [15]. Scar functions were conjectured to be related to a fractal dimension of the classical repeller, the set of initial conditions which remains trapped in the scattering region for all, positive and negative times, of a dynamical evolution up to the order of the system’s Ehrenfest time. This basis is adequate for the calculation of the small fraction of resonances which have small decay rates, usually the most important ones, without having to consider the multitude of rapidly decaying states. Also, it provides a tool for studying localization on classical structures more directly, and allows a natural semiclassical approach to resonance wave functions.

This method was used in [15] to reproduce the main resonances of an open baker map for a specific value of $\hbar$. In the present work we focus on the scaling of the method and show that it is compatible with the fractal Weyl law, not only for the baker but also for a cat map, which is more generic. We also discuss the ability of method to reproduce eigenfunctions. We find that a mixed quantity involving both types of functions (right and left), which has been introduced in [16], can be accurately reproduced. The paper is organized as follows. Section II is focused on reviewing the quantum and the classical versions of the systems that we have used in our study: the open baker and cat maps. In Section III we discuss the method and its results. Finally, we present our conclusions in Section IV.

II. OPEN QUANTUM MAPS

Maps are paradigmatic systems in classical and quantum chaos because of their simplicity [17–19]. We will consider maps defined on the torus. When quantizing them, boundary conditions must be imposed for both the position and momentum representations. This amounts to taking $\langle q + 1|\psi\rangle = e^{i2\pi\chi q}\langle q|\psi\rangle$, and $\langle p + 1|\psi\rangle = e^{i2\pi\chi p}\langle p|\psi\rangle$, with $\chi_q, \chi_p \in [0, 1)$. This implies a Hilbert space of finite dimension $N = (2\pi\hbar)^{-1}$, and the semiclassical limit is approached for large $N$. The system’s propagator becomes a $N \times N$ matrix. The discrete set of position and momentum eigenstates is given by $|q_j\rangle = |(j + \chi_q)/N\rangle$ and $|p_j\rangle = |(j + \chi_p)/N\rangle$ with $j \in \{0, \ldots, N-1\}$. They are related by a discrete Fourier transform, i.e. $\langle p_k|\psi_j\rangle = \frac{1}{\sqrt{N}} e^{-2\pi i(j + \chi_q)(k + \chi_p)/N} = (G_N^{\chi_q, \chi_p})_{jk}$.

We consider a certain region of the torus to be the opening, through which particles can escape. Its quantization is implemented by means of a projection operator $P$ on its complement. We always choose a finite strip parallel to the $p$ axis and corresponding to a
The classical (tri)baker map

\[ B(q, p) = \begin{cases} (3q, p/3) & \text{if } 0 \leq q < 1/3 \\ (3q - 1, (p + 1)/3) & \text{if } 1/3 \leq q < 2/3 \\ (3q - 2, (p + 2)/3) & \text{if } 2/3 \leq q < 1 \end{cases} \]  

is an area-preserving, uniformly hyperbolic, piecewise-linear and invertible map with Lyapunov exponent \( \lambda = \ln 3 \). Following [20, 21], the quantum version is defined in terms of the discrete Fourier transform in position representation as

\[ U^B = G^{-1}_N \begin{pmatrix} G_{N/3} & 0 & 0 \\ 0 & G_{N/3} & 0 \\ 0 & 0 & G_{N/3} \end{pmatrix}, \]  

where antiperiodic boundary conditions are imposed, \( \chi_q = \chi_p = 1/2 \). For this system we always take the opening as the region \( 1/3 < q < 2/3 \).

The classical cat maps are of the form

\[ \left( \begin{array}{c} q' \\ p' \end{array} \right) = C \left( \begin{array}{c} q \\ p \end{array} \right) \mod 1 = \left( \begin{array}{cc} c_{11} & c_{12} \\ c_{21} & c_{22} \end{array} \right) \left( \begin{array}{c} q \\ p \end{array} \right) \mod 1, \]  

where the \( c_{ij} \) must be integers to ensure continuity and the conditions \( \text{Tr}C > 2 \) and \( \det C = 1 \) are imposed to make the map hyperbolic and area-preserving. Here, we consider

\[ C = \begin{pmatrix} 2 & 1 \\ 3 & 2 \end{pmatrix}, \]  

for which the Lyapunov exponent is \( \log(2 + \sqrt{3}) \) and the stable and unstable directions are \( s = (-\sqrt{3}, 1) \) and \( u = (\sqrt{3}, 1) \). Quantization of cat maps was first introduced in Ref. [18] and discussed in [22]. For the case considered here, with periodic boundary conditions \( \chi_q = \chi_p = 0 \), this results in

\[ U^C(q', Q) = e^{(Q^2 - Q'^2 + Q^{22})/N}, \]  

where \( q = Q/N \) and \( q' = Q'/N \).

We note that for the baker map the opening corresponds to a cell in the Markov partition. As a consequence, the repeller is given in terms of an exactly self-similar fractal, the well known middle-third Cantor set. In that respect the cat map is more generic, since its stable and unstable manifolds intersect the opening transversally.

\[ \langle \Psi_n | \Psi_{n'} \rangle = \delta_{nm}, \]  

Their norm is arbitrary, but one may choose \( \langle \Psi_n | \Psi_{n'} \rangle = \langle \psi_n | \psi_{n'} \rangle \).

FIG. 1: Exact spectrum (circles) and our results (crosses), for the baker map. The pairs \( (N, N_\gamma) \) consisting of the Hilbert space dimension \( N \) and the number of scar functions \( N_\gamma \) are: a) (81, 51); b) (177, 105); c) (597, 291) and d) (1821, 471). We have chosen \( N_d \approx 4N^{d/2} \) where \( d \) is the dimension of the classical repeller.

III. METHOD AND RESULTS

Scar functions are special wavefunctions constructed by taking into account classical information in the neighborhood of a periodic orbit [23–29]. They have been developed for closed systems and are the building blocks of the semiclassical theory of short periodic orbits, by means of which one can find eigenvalues and eigenfunctions of a quantum system starting from purely classical quantities. For open systems they were introduced in Ref. [15]. In this section we review their construction and show a few examples.

Let \( \gamma \) be a periodic orbit of an open map (it must therefore belong to the repeller) of fundamental period \( L \), i.e. it consists of \( L \) different points in the torus:

\[ (q_0, p_0), (q_1, p_1), \ldots, (q_{L-1}, p_{L-1}), (q_L, p_L) = (q_0, p_0). \]  

We associate with \( \gamma \) a total of \( L \) scar functions. Initially, we define coherent states \( |q_j, p_j \rangle \) for each point of the orbit and a linear combination of them called a periodic orbit mode,

\[ |\phi_k^j \rangle = \frac{1}{\sqrt{L}} \sum_{j=0}^{L-1} \exp(-2\pi i(j A_k^j - N \theta_j)) |q_j, p_j \rangle. \]  

Here \( k \in \{0, \ldots, L - 1\} \) and \( \theta_j = \sum_{i=0}^j S_i \), where \( S_i \) is the action acquired by the \( i \)th coherent state in one step of the map. The total action of the orbit is \( \theta_L = S_\gamma + k ) L \).
The right and left scar functions associated with the periodic orbit are defined through the propagation of these modes under the open map. Namely,

$$|\psi^R_{\gamma,k}\rangle = \frac{1}{N^R_{\gamma}} \sum_{t=0}^{\tau} \tilde{U}^t e^{-2\pi i A^r_{\gamma} t} \cos \left( \frac{\pi t}{2\tau} \right) |\phi^k_{\gamma}\rangle,$$

(8) and

$$\langle \psi^L_{\gamma,k} | = \frac{1}{N^L_{\gamma}} \sum_{t=0}^{\tau} \langle \phi^k_{\gamma} | \tilde{U}^t e^{-2\pi i A^l_{\gamma} t} \cos \left( \frac{\pi t}{2\tau} \right).$$

The constants $N^R,L_{\gamma}$ are chosen such that $\langle \psi^R_{\gamma,k} | \psi^R_{\gamma,k} \rangle = \langle \psi^L_{\gamma,k} | \psi^L_{\gamma,k} \rangle$ and $\langle \psi^L_{\gamma,k} | \psi^R_{\gamma,k} \rangle = 1$. The cosine is used to introduce a smooth cutoff. The time scale of the propagation, $\tau$, is taken proportional to the system’s Ehrenfest time.

We use these functions to construct an approximate basis in the Hilbert space to diagonalize our propagator. We select a number of short periodic orbits that approximately cover the repeller, and eigenvalues and eigenfunctions are obtained by solving a generalized eigenvalue problem [15]. In this way, we isolate the relevant information needed to construct just the long lived resonances, without calculating the others. According to the fractal Weyl law, the number of such resonances grows like $N^{d/2}$, where $d$ is a fractal dimension of the classical repeller. Our method takes advantage of this fact: the number of scar functions that we need to obtain a reasonable approximation to the long-lived sector of the spectrum, denoted $N_s$, is of the order of $N^{d/2}$. The dimension of the matrix to be diagonalized is thus substantially reduced.

Exact spectra and the results of our method are shown in Fig. 1 for the baker map. We notice a very clear gap like $N^{d/2}$, where $d$ is a fractal dimension of the classical repeller. Our method takes advantage of this fact: the number of scar functions that we need to obtain a reasonable approximation to the long-lived sector of the spectrum, denoted $N_s$, is of the order of $N^{d/2}$. The dimension of the matrix to be diagonalized is thus substantially reduced.
while the scaling is preserved, although it is able to provide very accurate eigenvalues, the corresponding eigenfunctions are not necessarily well reproduced. We show in Fig. 3 the right and left eigenfunctions of the eigenvalue $z = 0.895$ of the baker map for $N = 243$. We see that the results from our method have significant differences compared to the exact ones, in regions away from the repeller. We also show analogous results for the cat map ($z = 0.722, N = 100$) in Fig. 4. Differences are not as noticeable in this case.

The method is, however, able to accurately reproduce the mixed representation $h_n(q, p) = |\langle q, p | \Psi_n^R \rangle|^2$ which was recently introduced in [10]. The reason for that is that this phase space quantity is supported on the intersection of the individual supports, which is precisely the repeller where our scar functions live. In Fig. 5 we can clearly see that the values of $h_n(q, p)$ computed with our method indeed coincide with the exact ones for both systems.

IV. CONCLUSIONS

We have shown in two paradigmatic models that our recently developed method [12] to obtain quantum resonances of chaotic systems from their classical properties indeed shows the same scaling as the fractal Weyl law. Namely, only a fraction $N^{d/2}$ (where $d$ is the dimension of the classical repeller) of our special basis states are required to provide a good approximation to the long-lived sector of the spectrum. When the Hilbert space dimension $N$ becomes large, this actually represents only a small fraction of $N$. We found that the method gives good but not excellent approximations to the right and left resonant eigenstates independently, because of the very limited support of the basis states we use. However, a mixed quantity involving both right and left eigenstates can be successfully obtained. Perhaps with some modification the method could also reproduce them, but further investigation is needed.
