ON THE VANISHING OF DISCRETE SINGULAR CUBICAL HOMOLOGY FOR GRAPHS

HÉLÈNE BARCELO, CURTIS GREENE, ABDUL SALAM JARRAH, AND VOLKMAR WELKER

Abstract. We prove that if \( G \) is a graph without 3-cycles and 4-cycles, then the discrete cubical homology of \( G \) is trivial in dimension \( d \), for all \( d \geq 2 \). We also construct a sequence \( \{G_d\} \) of graphs such that this homology is non-trivial in dimension \( d \) for \( d \geq 1 \). Finally, we show that the discrete cubical homology induced by certain coverings of \( G \) equals the ordinary singular homology of a 2-dimensional cell complex built from \( G \), although in general it differs from the discrete cubical homology of the graph as a whole.

1. Introduction

We will be concerned with a discrete (singular) cubical homology theory for graphs, originally defined in [3] for general metric spaces. The definition in [3] had its roots in [5], which introduced a discrete homotopy theory for simplicial complexes. Graphical versions or equivalently 1-dimensional versions of this theory were studied by several authors (see [6], [7], [10]), and [2] proposed the problem of finding a corresponding homology theory.

In [4], the authors developed tools for computing the discrete singular cubical homology groups \( \mathcal{H}^{\text{Cube}}_d(G) \) (see Section 2 of this paper for a precise definition) for many families of graphs \( G \). Since relevant chain groups grow super-exponentially in rank, direct computation presents formidable difficulties, even for small graphs. For example, when \( G = \mathbb{Z}_5 \), the pentagon (5-cycle) graph, the methods of [4] were not sufficient to determine \( \mathcal{H}^{\text{Cube}}_d(G) \) beyond \( d = 3 \). In the present paper we prove that \( \mathbb{Z}_5 \) has vanishing discrete singular cubical homology in dimension \( d \), for all \( d \geq 2 \). This result was conjectured in [4]. In fact we will prove a stronger conjecture, also made in [4].

Theorem 1.1. Let \( G \) be any graph containing no 3-cycles or 4-cycles. Then \( \mathcal{H}^{\text{Cube}}_d(G) = (0) \) for all \( d \geq 2 \).

Of course, in classical theory, where graphs are 1-dimensional CW-complexes, all graphs have trivial homology in dimension \( d \geq 2 \). However, the discrete cubical homology of [3] is notably different: for example, 4-cycles are homologically trivial in all dimensions, and 4-cycles play a special role that was also apparent in...
the homotopy theory of [3]. Examples of graphs with non-vanishing homology in
dimension \( d \geq 2 \) exist (e.g., [3], [4]), but can be challenging to construct and verify.
In that spirit, we note that the following conjecture appears in [4], and remains
open.

**Conjecture 1.2.** For any graph \( G \), there exists an integer \( N \) such that \( \mathcal{H}^\text{Cube}_{d}(G) = (0) \) for all \( d \geq N \).

For arbitrarily large \( d \), it is not obvious that there should exist graphs with
non-vanishing \( d \)-homology. Proposition 5.3 of [3] constructs an infinite sequence of
graphs \( \{G_d\}_{d \geq 1} \), such that

\[
\mathcal{H}^\text{Cube}_{d+1}(G_{d+1}) = \mathcal{H}^\text{Cube}_{d}(G_d) \quad \text{for all } d \geq 1.
\]

(1)

For appropriately chosen \( G_1 \) this yields a sequence of graphs with non-vanishing
\( d \)-homology, for arbitrarily large \( d \). However, the argument in [3] is not sufficient to
prove (1) in full generality, since it relies on a discrete version of the Mayer-Vietoris
sequence whose hypotheses are not satisfied for \( d > 1 \). In the present paper we will
show that a small modification of the definition of \( G_d \) in [3] makes the argument
correct, thus yielding a (different) sequence of graphs with non-vanishing homology
in arbitrarily high dimension.

Our principal tool in proving Theorem 1.1 is a subdivision map that allows
computation of homology to be restricted to “small” singular cubes. This approach
is standard in classical treatments of singular homology, see e.g., [14], but for the
discrete cubical case the details are significantly different and new techniques are
required.

The paper is organized as follows. Section 2 reviews the basic definitions of
discrete cubical homology for graphs, following [3]. Section 3 defines the subdivision
map and proves the above mentioned conjecture when \( G = \mathbb{Z}_5 \). In fact the argument
proves the same result for any cycle \( \mathbb{Z}_n \) with \( n \geq 5 \). Section 4 introduces the
machinery necessary to extend the proof for \( G = \mathbb{Z}_5 \) to arbitrary graphs without 3-
cycles and 4-cycles. The key step is to show that every singular cube with codomain
\( G \) can be lifted to the universal covering graph of \( G \). Once this has been established,
we show how the constructions used in Section 3 extend to the general case. In
Section 5 we show how to modify the construction in [3] to obtain an infinite
sequence of graphs \( \{G_d\}_{d \geq 1} \) such that \( G_d \) has non-vanishing homology in dimension
\( d \). Section 6 concludes with general remarks about issues involved in generalizing
the results in this paper to arbitrary graphs.

Since we will be discussing and comparing several different homology theories
for graphs, it may be helpful to clarify our terminology in advance. Our primary
focus is on the **discrete singular cubical homology** of a graph \( G \), defined in Section
2). It will be denoted by \( \mathcal{H}^\text{Cube}(G) \) and occasionally called, simply, the **discrete
cubical homology**. If \( X \) is any topological space, one can construct a **singular cubical
homology** (e.g., [14]) and a **singular simplicial homology** (e.g., [12],[15]). Since these
are equal under assumptions relevant to this paper, they will both be called the
(ordinary) **singular homology** of \( X \) and denoted by \( \mathcal{H}^\text{Sing}(X) \). We will also have
occasion to use the fact that \( \mathcal{H}^\text{Sing}(X) \approx \mathcal{H}^\text{Cell}(X) \), the **cellular homology** of \( X \),
when \( X \) is a CW-complex.
2. Background: discrete cubical homology of graphs

We will briefly review the definitions relevant to this paper, referring the reader to [1] for more details and examples, and also to [9] for graph theory definitions and terminology. For any positive integer $n$, let $[n] := \{1, \ldots, n\}$. Throughout the paper, all homology computations will be done over a commutative ring with identity, denoted $R$.

For $d \geq 1$, the discrete $d$-cube $Q_d$ is the graph with vertex set
\[
V(Q_d) = \{(a_1, \ldots, a_d) \mid a_i \in \{0, 1\}, 1 \leq i \leq d\},
\]
and edge set $E(Q_d)$ consisting of those pairs of vertices $(a, b)$ differing in exactly one position. By convention, $Q_0$ is the 1-vertex graph with no edges.

If $G$ and $H$ are simple graphs, i.e., undirected graphs without loops or multiple edges, a graph homomorphism (or graph map) $\sigma : G \to H$ is a map from $V(G)$ to $V(H)$ such that, if $(a, b) \in E(G)$ then either $\sigma(a) = \sigma(b)$ or $(\sigma(a), \sigma(b)) \in E(H)$. A graph homomorphism $\sigma : Q_d \to G$ is called a singular $d$-cube on $G$.

For each $d \geq 0$, let $L^\text{Cube}_d(G)$ be the free $R$-module generated by all singular $d$-cubes on $G$. For $d \geq 1$ and each $i \in [d]$, we define two face maps $f^+_i$ and $f^-_i$ from $L^\text{Cube}_d(G)$ to $L^\text{Cube}_{d-1}(G)$ such that, for $\sigma \in L^\text{Cube}_d(G)$ and $(a_1, \ldots, a_{d-1}) \in Q_{d-1}$:
\[
f^+_i \sigma(a_1, \ldots, a_{d-1}) := \sigma(a_1, \ldots, a_{i-1}, 1, a_i, \ldots, a_{d-1}),
\]
\[
f^-_i \sigma(a_1, \ldots, a_{d-1}) := \sigma(a_1, \ldots, a_{i-1}, 0, a_i, \ldots, a_{d-1}).
\]

For $d \geq 1$, a singular $d$-cube $\sigma$ is called degenerate if $\sigma$ does not depend on at least one of its variables, that is, $f^+_i \sigma = f^-_i \sigma$, for some $i \in [d]$. Otherwise, $\sigma$ is called non-degenerate. By definition every 0-cube is non-degenerate.

For each $d \geq 0$, let $D^\text{Cube}_d(G)$ be the $R$-submodule of $L^\text{Cube}_d(G)$ generated by all degenerate singular $d$-cubes, and let $C^\text{Cube}_d(G) = L^\text{Cube}_d(G)/D^\text{Cube}_d(G)$, whose elements are called $d$-chains. Clearly, the cosets of non-degenerate $d$-cubes freely generate $C^\text{Cube}_d(G)$.

Furthermore, for each $d \geq 1$, define the boundary operator
\[
\partial^\text{Cube}_d : L^\text{Cube}_d(G) \to L^\text{Cube}_{d-1}(G)
\]
such that, for each singular $d$-cube $\sigma$,
\[
\partial^\text{Cube}_d(\sigma) = \sum_{i=1}^d (-1)^i (f^-_i \sigma - f^+_i \sigma)
\]
and extend linearly to all chains in $L^\text{Cube}_d(G)$. When there is no danger of confusion, we will abbreviate $\partial^\text{Cube}_d$ as $\partial_d$. If one sets $L^\text{Cube}_1(G) = D^\text{Cube}_1(G) = (0)$ then one can define $\partial^\text{Cube}_0$ as the trivial map from $L^\text{Cube}_0(G)$ to $L^\text{Cube}_1(G)$.

It is easy to check that, for $d \geq 0$, $\partial_d[D^\text{Cube}_d(G)] \subseteq D^\text{Cube}_{d-1}(G)$ and $\partial_d \partial_{d+1} \sigma = 0$ (see [3]). Hence, using the same notation, we may define a boundary operator $\partial_d : C^\text{Cube}_d(G) \to C^\text{Cube}_{d-1}(G)$, and $C^\text{Cube}(G) = \{C^\text{Cube}_d(G), \partial_d\}_{d \geq 0}$ is a chain complex of free $R$-modules.

**Definition 2.1.** For $d \geq 0$, denote by $H^\text{Cube}_d(G)$ the $d$th homology group of the chain complex $C^\text{Cube}(G)$. In other words, $H^\text{Cube}_d(G) := \text{Ker} \partial_d / \text{Im} \partial_{d+1}$.

We denote singular $d$-cubes $\sigma : Q_d \to G$ by sequences of length $d^d$, where the $i$th term is the value of $\sigma$ on the $i$th vertex, and the vertices of $Q_d$ are indexed in colexicographic order. For example, if $G$ is a path with vertices labeled $\{1, 2, 3\}$,
then the sequence (1, 2, 1, 2, 3, 3, 2) represents the singular 3-cube with labels as illustrated below.

\[
\begin{array}{c}
000 \\
001 \\
010 \\
011 \\
100 \\
101 \\
110 \\
111 \\
\end{array}
\]

By convention, we will represent each coset in \( C^\text{Cube}_d(G) \) by the unique coset representative in which all terms are non-degenerate.

### 3. Subdivision Map for the Pentagon

In this section we prove that \( H^\text{Cube}_d(G) = (0) \) for all \( d \geq 2 \) when \( G = \mathbb{Z}_5 \). The key step is to reduce the computation to considering singular cubes \( \sigma : Q_d \to \mathbb{Z}_5 \) whose image has size at most 2.

#### Definition 3.1

For any graph \( G \),

\[
C_d^{(2)}(G) = \{ \sigma \in C_d(G) \mid |\text{Im}(\sigma)| \leq 2 \}.
\]

#### Theorem 3.2 (Subdivision for \( \mathbb{Z}_5 \))

For all \( d \geq 1 \), there exists a map \( S^d : C_d(\mathbb{Z}_5) \to C_d(\mathbb{Z}_5) \) such that

1. \( S^d \) is a chain map.
2. \( \text{Im}(S^d) \subseteq C_d^{(2)}(\mathbb{Z}_5) \).
3. There exists maps \( h_{d-1} : C_{d-1}(\mathbb{Z}_5) \to C_d(\mathbb{Z}_5) \) and \( h_d : C_d(\mathbb{Z}_5) \to C_{d+1}(\mathbb{Z}_5) \) such that
   (i) for all \( \sigma \in C_d(\mathbb{Z}_5) \), \( \sigma - S^d(\sigma) = h_{d-1}\partial_d(\sigma) + \partial_{d+1}h_d(\sigma) \), and
   (ii) for all \( \sigma \in C_d^{(2)}(\mathbb{Z}_5) \), \( h_d(\sigma) \in C_{d+1}(\mathbb{Z}_5) \).

Before proving Theorem 3.2 we will show that it implies one of our principal results.

#### Corollary 3.3

For all \( d \geq 1 \), \( H^\text{Cube}_d(C(\mathbb{Z}_5)) = H^\text{Cube}_d(C^{(2)}(\mathbb{Z}_5)) \).

**Proof.** We may represent the maps defined in Theorem 3.2 by the following diagram.

Property (3i) defines a chain homotopy between the identity map \( I \) and \( iS \) where \( i \) denotes the inclusion map from \( C^{(2)} \) to \( C \). Since \( S \) and \( i \) are chain maps, they
induce maps $S_* : H(C) \to H(C^{(2)})$ and $i_* : H(C^{(2)}) \to H(C)$ on homology, and chain homotopy implies $I_* = (iS)_* = i_*S_*$. Since $S_*$ has a left inverse, it is injective.

By property (3ii) we can also regard $h_d$ as a map from $C^{(2)}_d$ to $C^{(2)}_{d+1}$, and we obtain the following similar diagram.

This describes a homotopy between $I : C^{(2)} \to C^{(2)}$ and $Si : C^{(2)} \to C^{(2)}$. Hence, for the induced maps on homology, we have $I_* = (Si)_* = S_*i_*$ which proves that $S_*$ has a right inverse. Hence $S_*$ is surjective, and we conclude that it is an isomorphism of homology.

□

Proof of Theorem 3.2. We will first construct, for any integer $N \geq 2$, an operator $S^N : C_d(\mathbb{Z}_5) \to C_d(\mathbb{Z}_5)$ which maps a singular cube $\sigma \in C_d(\mathbb{Z}_5)$ to a sum of $N^d$ singular cubes. Then, in order to ensure property (3i) of Theorem 3.2 we will specialize to $N = d$.

The construction proceeds in several steps, which we will first illustrate by a small example with $N = 3, d = 2$. Consider the singular 2-cube $\sigma = (1, 2, 2, 3) \in C_2(\mathbb{Z}_5)$ illustrated by the following picture.

The steps in the construction of $S^3(\sigma)$ are as follows:

STEP 1: Lift $\sigma$ to a graph map $\tilde{\sigma} : Q_2 \to \mathbb{Z}$. In this case, the above picture also represents $\tilde{\sigma}$, but this may not be true in general.

STEP 2: Subdivide $Q_2$, creating a grid $Q_3^2$ with nine small subsquares. Extend $\tilde{\sigma}$ to a map $\tilde{\sigma}^3 : Q_3^2 \to \mathbb{Z}$ by computing weighted averages along lines.

STEP 3: Round down, obtaining a map $\lfloor \tilde{\sigma}^3 \rfloor : Q_3^2 \to \mathbb{Z}$, and then reduce mod 5, obtaining a map $[\tilde{\sigma}^3] : Q_3^2 \to \mathbb{Z}_5$.

The results of steps 2 and 3, constructing $\tilde{\sigma}^3$ and $[\tilde{\sigma}^3]$, may be represented as follows:
STEP 4: Finally, define $S^3(\sigma)$ to be the sum of the (non-degenerate) small subcubes appearing in $[\tilde{\sigma}^3]$. That is,

$$S^3(\sigma) = 2(1, 1, 1, 2) + 3(1, 2, 2, 2) + (2, 2, 2, 3).$$

Next we explain the construction of $S^N$ in general, and show that it satisfies property (1) of Theorem 3.2.

**Definition 3.4** (Discrete $N$-grid in dimension $d$). For any $d, N \geq 1$, let

$$Q^N_d = \{(a_1, \ldots, a_d) | a_i \in \{0, \ldots, N\}\}.$$

**Lemma 3.5** (Lifting lemma). If $\sigma : Q^d \to \mathbb{Z}_5$ is a singular $d$-cube, there exists a graph map $\tilde{\sigma} : Q^d \to \mathbb{Z}$ such that the diagram

$$\begin{array}{ccc}
Q^d & \xrightarrow{\tilde{\sigma}} & \mathbb{Z} \\
\sigma \downarrow & & \downarrow \\
\mathbb{Z}_5 & & 
\end{array}$$

commutes. This map is unique up to translation of its image.

**Proof of Lemma 3.5.** Choose $v_0 = (0, \ldots, 0)$ in $Q^d$ as a basepoint, and define $\tilde{\sigma}(v_0) \in \mathbb{Z}$ to be the minimal positive representative of the residue class of $\sigma(v_0) \in \mathbb{Z}_5$. Define $\tilde{\sigma}$ on all of $Q^d$ by extending along paths from $v_0$ by the following rules:

if $\tilde{\sigma}(v) = k \in \mathbb{Z}$ has been defined, and $u$ is adjacent to $v$ in $Q^d$, then

$$\tilde{\sigma}(u) = \begin{cases} 
  k & \text{if } \sigma(u) = \sigma(v) \\
  k + 1 & \text{if } \sigma(u) = \sigma(v) + 1 \mod 5 \\
  k - 1 & \text{if } \sigma(u) = \sigma(v) - 1 \mod 5.
\end{cases}$$

It is clear that if $\tilde{\sigma}$ is well defined, then it is a graph map. To show that it is well defined, it suffices to show that applying (2) iteratively defines $\tilde{\sigma}$ unambiguously around any loop in $Q^d$. For completeness, we sketch a short proof of this fact, which is probably well known.

Suppose $\gamma = (v_0, v_1, \ldots, v_{2k} = v_0)$ is a loop of length $2k$ in $Q^d$. We may represent $\gamma$ as a loop in the Boolean lattice $2^d$, where $v_0$ corresponds to the empty set and steps consist of additions or deletions of elements in $[d]$. If additions and deletions of elements $x \in [d]$ are encoded by $x$ and $\overline{x}$, respectively, then $\gamma$ may be represented by a word in these symbols. For example, $w = 353253$ represents the path

$$\emptyset \to 3 \to 35 \to 5 \to 25 \to 2 \to 23.$$

A word $w$ represents a path in $Q^d$ if and only if for each $x \in [d]$, the occurrences of $x$ and $\overline{x}$ in $w$ form an alternating subsequence beginning with $x$. It represents
a loop if and only if, for all \( x \), the sequence also ends with \( \bar{x} \). The property of representing a loop is preserved if we transpose symbols \( w_i \) and \( w_{i+1} \), where \( w_i = x \) or \( \bar{x} \), \( w_{i+1} = y \) or \( \bar{y} \), and \( x \neq y \). Consequently, if \( w \) represents a loop \( \gamma(w) \) beginning and ending at \( \emptyset \), we can transform \( w \) by adjacent transpositions into a word of the form \( w^* = x\bar{y}y \cdots z\bar{z} \) with the same properties. Further, if \( \tilde{\sigma}(w) \) is the result of applying \( \tilde{\sigma} \) to the loop \( \gamma(w) \) in \( Q_d \), it is straightforward to show (by examining a small number of cases) that transforming adjacent letters in \( w \) does not change the endpoint of \( \tilde{\sigma}(w) \). Since \( \gamma(w^*) \) obviously maps to a closed loop in \( \mathbb{Z}_5 \), the same must be true of \( \gamma(w) \), and we are done. \( \square \)

Next we extend \( \tilde{\sigma} \) to the interior of \( Q^N_d \), obtaining a map \( \tilde{\sigma}^N : Q^N_d \rightarrow \mathbb{Q} \).

**Definition 3.6** (Weighted \( Q \)-averaging). Suppose \( \sigma : Q_d \rightarrow \mathbb{Z}_5 \) is a graph map, and \( \tilde{\sigma} : Q_d \rightarrow \mathbb{Z} \) extends \( \sigma \) as described in Lemma 3.5. Define \( \tilde{\sigma}^N : Q^N_d \rightarrow \mathbb{Q} \) as follows: if \((a_1, \ldots, a_d)\) is a vertex of \( Q^N_d \), then

\[
\tilde{\sigma}^N(a_1, \ldots, a_d) = \sum_{v=(\epsilon_1, \ldots, \epsilon_d)} w_v(a_1, \ldots, a_d)\tilde{\sigma}(\epsilon_1, \ldots, \epsilon_d),
\]

where the sum is over all vertices \( v = (\epsilon_1, \ldots, \epsilon_d) \in Q_d \), where \( \epsilon_i \in \{0, 1\} \), and where the weights \( w_v(a_1, \ldots, a_d) \) are defined by

\[
w(\epsilon_1, \ldots, \epsilon_d) = \prod_{i=1}^{d} \left\{ \begin{array}{ll}
1 - \frac{a_i}{N} & \text{if } \epsilon_i = 0 \\
\frac{a_i}{N} & \text{if } \epsilon_i = 1.
\end{array} \right.
\]

It is easy to see that for fixed \((a_1, \ldots, a_d)\) we have

\[
\sum_v w_v(a_1, \ldots, a_d) = 1.
\]

Thus, \( \tilde{\sigma}^N(a_1, \ldots, a_d) \) is a weighted average of \( \tilde{\sigma}(v) \), over all vertices \( v \) of \( Q_d \), taking values in \( \mathbb{Q} \). Furthermore, formula [Definition 3.6] is equivalent to a recursive construction, where \( \tilde{\sigma}^N \) is first defined on edges of \( Q_d \), then extending to higher dimensional faces by computing weighted averages along lines between corresponding points on opposing faces (in any order).

**Lemma 3.7.** If \( \sigma : Q_d \rightarrow \mathbb{Z}_5 \) is a graph map, then for any adjacent vertices \( u, v \) of \( Q^N_d \), we have

\[
|\tilde{\sigma}^N(u) - \tilde{\sigma}^N(v)| \leq 1/N.
\]

**Proof of Lemma 3.7.** If \( d = 1 \) this is immediate. Suppose, inductively, that we have proved Lemma 3.7 for maps with domain \( Q^N_{d-1} \). Then it holds for adjacent vertices on the outer faces of \( Q^N_d \), by the inductive construction of \( \tilde{\sigma}^N \). Suppose that \((u, v)\) is an interior edge of \( Q^N_d \). Draw lines perpendicular to \((u, v)\), meeting opposite faces of \( Q^N_d \) at points \( p, q, r \) and \( s \), as shown:
By hypothesis, both \( \hat{\sigma}^N(p) - \hat{\sigma}^N(q) \) and \( \hat{\sigma}^N(r) - \hat{\sigma}^N(s) \) lie in the interval \([-1/N, 1/N]\), and we also have
\[
\hat{\sigma}^N(u) = \alpha \hat{\sigma}^N(p) + (1 - \alpha)\hat{\sigma}^N(r), \quad \text{and} \quad \hat{\sigma}^N(v) = \alpha \hat{\sigma}^N(q) + (1 - \alpha)\hat{\sigma}^N(s)
\]
for some \( \alpha \in [0, 1] \). It follows that \( \hat{\sigma}^N(u) - \hat{\sigma}^N(v) \) is a convex combination of \( \hat{\sigma}^N(p) - \hat{\sigma}^N(q) \) and \( \hat{\sigma}^N(r) - \hat{\sigma}^N(s) \), and hence lies in \([-1/N, 1/N]\) as claimed. \(\square\)

**Definition 3.8.** If \( \sigma : Q_d \to \mathbb{Z}_5 \) is a graph map, then \( [\hat{\sigma}^N] : Q_d^N \to \mathbb{Z} \) is the map obtained by rounding down \( \hat{\sigma}^N \) at each vertex of \( Q_d^N \). That is,
\[
[\hat{\sigma}^N](a_1, \ldots, a_d) = [\hat{\sigma}^N(a_1, \ldots, a_d)].
\]
Finally, define
\[
[\hat{\sigma}^N](a_1, \ldots, a_d) = [\hat{\sigma}^N](a_1, \ldots, a_d) \mod 5 \in \mathbb{Z}_5.
\]

**Corollary 3.9.** Suppose that \( \sigma : Q_d \to \mathbb{Z}_5 \) is a graph map, and \( [\hat{\sigma}^N] : Q_d^N \to \mathbb{Z}_5 \) is defined as in \((7)\). Then

1. \( [\hat{\sigma}^N] : Q_d^N \to \mathbb{Z}_5 \) is a graph map.
2. If \( N \geq d \) and \( u, v \) are any vertices of a small subcube in \( Q_d^N \), then
\[
|[\hat{\sigma}^N](u) - [\hat{\sigma}^N](v)| \leq 1.
\]

In particular, the image of \( \hat{\sigma}^N \) restricted to each of the small subcubes in \( Q_d^N \) has size at most two.

**Proof of Corollary 3.7.** Statement (1) follows immediately from \( \underline{\text{Lemma 3.7}} \) and the elementary fact that if \( \alpha, \beta \in \mathbb{R} \) and \( |\alpha - \beta| \leq 1 \), then \( |\lfloor \alpha \rfloor - \lfloor \beta \rfloor| \leq 1 \). Statement (2) follows from \( \underline{\text{Lemma 3.7}} \) and the fact that any two vertices in \( Q_d \) can be linked by a path of length \( \leq d \). \(\square\)

Now we are finally in a position to define \( S^N \), by summing the restrictions of \( [\hat{\sigma}^N] \) to each of the small subcubes of \( Q_d^N \).

**Definition 3.10.** For any \( d \geq 1, N \geq 2 \), define \( S^N : C_d(\mathbb{Z}_5) \to C_d(\mathbb{Z}_5) \) by setting
\[
S^N(\sigma) = \sum_{q_d \in Q_d^N} [\hat{\sigma}^N](q_d),
\]
where \( \sigma \) a generator of \( C_d(\mathbb{Z}_5) \), and the sum is over all of the \( N^d \) small subcubes \( q_d \) of \( Q_d^N \).

The next corollary includes the first two parts of \( \underline{\text{Theorem 3.2}} \).

**Corollary 3.11.**

1. For all \( d \geq 1, N \geq 2 \), the map \( S^N \) is a chain map.
2. If \( \sigma \) is a generator of \( C_d(\mathbb{Z}_5) \), then each summand of \( S^d(\sigma) \) is a graph map with image of size at most 2.

**Proof of Corollary 3.11.** The essential step in proving (1) is to show that the definition of \( [\hat{\sigma}^N] \) on a face \( f_i^N Q_d^N \) of \( Q_d^N \) agrees exactly with the definition of \( [\hat{\sigma}^N] \) on \( Q_{d-1}^N \). We leave the verification of this fact to the reader. Internal cancellation of faces of small cubes then implies identity \( \partial_d S^N(\sigma) = S^N(\partial_d \sigma) \). Statement (2) is a consequence of \( \underline{\text{Corollary 3.9}} \). \(\square\)
It remains to prove part (3) of Theorem 3.2. We will define maps \( h_{d-1} \) and \( h_d \) and show that for all \( \sigma \in C_d(\mathbb{Z}_5) \),

\[
\partial_{d+1} h_d(\sigma) = \sigma - S^d(\sigma) - h_{d-1} \partial_d(\sigma) \pm \text{degenerate terms.}
\]

The argument generally follows [14, §7.7], where a similar construction is used to obtain an analogous result for ordinary cubical simplicial homology. However, there are significant variations, including the need for subdivisions \( S^N \) with \( N > 2 \) and also for more than two levels in the definition of \( h_d \) and \( h_{d-1} \).

**Definition 3.12.** For \( \sigma \in C_d(\mathbb{Z}_5) \), we define \( h_d \) by the following process.

1. First construct a \( \mathbb{Q} \)-labeling \( \tilde{\gamma}(\sigma) \) of the \((d+1)\)-dimensional grid \( Q_{d+1}^d = \{(a_1, \ldots, a_{d+1}) | 0 \leq a_i \leq d\} \) as follows:
   - The bottom face \((a_{d+1} = 0)\) is \( \tilde{\sigma}^d \) (the second step in constructing \( S^d(\sigma) \)).
   - The top face \((a_{d+1} = d)\) is \( T_d(\sigma) \), defined by the rule
     \[
     T_d(\sigma)(a_1, \ldots, a_d) = \tilde{\sigma}(\bar{a}_1, \ldots, \bar{a}_d), \quad \bar{a}_i = \begin{cases} 0 & \text{if } a_i = 0 \\ 1 & \text{if } a_i > 1. \end{cases}
     \]
   - Along each line from \((a_1, \ldots, a_d, 0)\) to \((a_1, \ldots, a_d, d)\), assign labels by computing equally spaced averages between \( \tilde{\gamma}(\sigma)(a_1, \ldots, a_d, 0) \) and \( \tilde{\gamma}(\sigma)(a_1, \ldots, a_d, d) \).
2. Transform \( \tilde{\gamma}(\sigma) \) into a \( \mathbb{Z} \)-labeling \( \lceil \tilde{\gamma}(\sigma) \rceil \) by rounding down, and then into a \( \mathbb{Z}_5 \) labeling \( [\tilde{\gamma}(\sigma)] \) by reducing mod 5.
3. Define \( h_d(\sigma) \) to be \((-1)^{d+1}\) times the sum of the \( d^d \) small subcubes in \( [\tilde{\gamma}(\sigma)] \).

This construction is designed to embody a proof of (8) for a single value of \( d \). For that purpose, \( h_{d-1} \) must be defined compatibly with \( h_d \), and not independently. More precisely, \( h_{d-1} \) is defined as in Definition 3.12 but on a grid of type \( Q_{d+1}^d \), not \( Q_{d-1}^d \). It will follow that the side faces of \( h_d(\sigma) \) appear as images of \( h_{d-1}(\sigma) \) applied to the faces of \( \sigma \).

The following partially labeled diagram illustrates the construction of \( h_2 : C_2(G) \to C_3(G) \) for a generic singular 2-cube \( \sigma = (a, b, c, d) \).
According to Definition 3.12 the vertex at the centroid of the grid should be labeled 
\[ \frac{1}{2}(d + \frac{a + b + c + d}{4}) = \frac{a + b + c + 5d}{8}. \]

**Proof of Theorem 3.3.** Part (3i). The main difficulty is showing that the labeling \( \bar{\gamma} \) defines a graph map from \( Q_d^d \) to \( \mathbb{Z}_5 \). Once this is done, verifying statement (3i) reduces to a purely formal calculation.

**Lemma 3.13.** If \( \sigma \in C_d(\mathbb{Z}_5) \), then in the \( \mathbb{Q} \)-labeling \( \bar{\gamma}(\sigma) \), every pair of adjacent labels differs by at most 1.

**Proof of Lemma 3.13.** In the original \( \sigma \), every pair of labels (adjacent or not) differs by at most \( d \). This property carries over to \( \bar{\sigma}^d \), and every new edge in \( \bar{\gamma}(\sigma) \) is obtained by subdividing a segment from one of the original labels to a label of \( \bar{\sigma}^d \) into \( d \) equal pieces. Hence the lengths of these pieces are at most \( \frac{(1/d)}{d} = 1 \).

As we have observed in Corollary 3.9, rounding preserves the property that labels of adjacent vertices differ by at most 1, and reducing mod 5 translates this into adjacency in \( \mathbb{Z}_5 \). It follows that \( \bar{\gamma}(\sigma) \) defines a graph map from \( Q_d^d \) to \( \mathbb{Z}_5 \).

The proof of statement (8) is now straightforward. When the top face \( (a_{d+1} = d) \) is expanded into small cubes, it consists of \( \sigma \) plus degenerate terms. When the bottom face \( (a_{d+1} = 0) \) is expanded, it is exactly \( S^d(\sigma) \). Furthermore, the sign \( (-1)^{d+1} \) of \( h_d(\sigma) \) has been chosen exactly so that the terms in \( \sigma - S^d(\sigma) \) appear with correct signs in the expansion of \( \partial_{d+1}h_d(\sigma) \). It is easy to see that the remaining terms (aside from \( \sigma \)) coming from the top face are all degenerate. Finally, \( h_{d-1} \) has been defined exactly so that terms in the expansion of \( \partial_{d+1}h_d(\sigma) \) arising from faces other than \( a_{d+1} = 0 \) and \( a_{d+1} = d \) are accounted for (with proper sign) by \( h_{d-1}\partial_d(\sigma) \). This completes the proof of part (3i) of Theorem 3.2.

**Proof of Theorem 3.3.** Part (3ii). We must show that if \( \sigma \) has two labels, then every non-degenerate cube in the expansion of \( h_d(\sigma) \) has two labels. Suppose \( \sigma \) has two labels, and that these are mapped to \( t \) and \( t + 1 \) by the lifting of \( \sigma \) to \( \bar{\sigma} \). Then the top face \( T_d(\sigma) \) has these same labels, and the bottom face \( \bar{\sigma}^d \) has rational labels in the interval \([t, t + 1] \). By construction, the remaining labels of \( h_d(\sigma) \) all lie in the interval \([t, t + 1] \). When these are rounded down, the results will again all be equal to \( t \) or \( t + 1 \), and the result follows.

This completes the proof of Theorem 3.2.

Theorem 3.2 shows that computing the homology of \( \mathbb{Z}_5 \) can be reduced to computing the homology of the chain complex \( C^{(2)}(\mathbb{Z}_5) \), i.e. the complex generated by singular cubes whose image has size \( \leq 2 \). The second main result of this section shows that the complex \( C^{(2)}(\mathbb{Z}_5) \) has trivial homology in all dimensions \( d \geq 2 \).

**Theorem 3.14.** For all \( d \geq 2 \), \( H_d(C^{(2)}(\mathbb{Z}_5)) = (0) \), and consequently \( H_d(C(\mathbb{Z}_5)) = (0) \).

**Proof of Theorem 3.14.** Let \( e = (i, i + 1) \pmod{5} \) be an edge of \( \mathbb{Z}_5 \). For \( d \geq 0 \), define 
\[ C^{(e)}_d(\mathbb{Z}_5) = \{ \sigma \in C_d(\mathbb{Z}_5) \mid \text{Im}(\sigma) \subseteq e \}. \]

Clearly, for \( d \geq 1 \) we have \( \partial C^{(e)}_d(\mathbb{Z}_5) \subseteq C^{(e)}_{d-1}(\mathbb{Z}_5) \). Furthermore, for \( d \geq 1 \) we have \( C_d(\mathbb{Z}_5) = \bigoplus_e C^{(e)}_d(\mathbb{Z}_5) \). It follows that for \( d \geq 2 \), \( H_d(C(\mathbb{Z}_5)) \approx \bigoplus_e H_d(C^{(e)}(\mathbb{Z}_5)) \).
But $\mathcal{H}_d(C^e(S_3))$ is the $d^{th}$ homology of a contractible graph, and hence is trivial for all $d > 0$ (see [4] for precise definitions, and for a proof of this result). □

4. Graphs without 3-Cycles or 4-Cycles

In this section we will extend Theorem 3.2, Corollary 3.3, and Theorem 3.14 to arbitrary graphs $G$ containing no 3-cycles or 4-cycles.

Theorem 4.1. Suppose that $G$ is a graph with no 3-cycles or 4-cycles. Then, for $d \geq 1$ there exists a map $S^d : C_d(G) \to C_d(G)$ such that

1. $S^d$ is a chain map,
2. $\text{Im}(S^d) \subseteq C_d^2(G)$, and
3. for $d \geq 1$, $S^d$ induces an isomorphism of homology $S^d_\ast : \mathcal{H}_d(C(G)) \to \mathcal{H}_d(C^2(G))$.

Furthermore, for $d \geq 2$, $\mathcal{H}_d(C^2(G)) = (0)$.

Proof. The proof will follow the steps in Section 3, showing that with small adjustments, all of the arguments generalize. In fact, the only significant challenge is generalizing Lemma 3.3 proving that singular cubes $\sigma$ with $\text{Im}(\sigma) = G$ can be lifted to a setting where averages can be computed. This will require constructing the universal covering graph $U(G)$ of a graph $G$, the discrete analog of a familiar topological object (see, e.g., [15, 12]).

Definition 4.2 (Graph coverings). Suppose that $G$ is a connected (undirected) graph.

1. A covering of $G$ by a graph $\tilde{G}$ is a map $p : \tilde{G} \to G$ such that for all $\tilde{x} \in \tilde{G}$, $p$ maps the star $E_p(\tilde{x})$ of $\tilde{x}$ (the set of edges adjacent to $\tilde{x}$) bijectively onto the star $E_p(x)$ of $p(\tilde{x})$.
2. A universal covering graph $U(G)$ of $G$ is a graph with a covering map $u : U(G) \to G$, such that for any covering $p : \tilde{G} \to G$ there exists a covering map $v : U(G) \to \tilde{G}$ such that $u = pv$.

Much of the theory of topological coverings carries over to graphs, considered as 1-dimensional cell complexes. Universal covering graphs seem to have been first constructed explicitly in [11]; see also, e.g., [13, 16] for other applications. For our purposes, we need the properties of $U(G)$ stated in the following lemma.

Lemma 4.3. Suppose that $G$ is a finite connected graph. Then

1. $U(G)$ exists and is unique up to isomorphism.
2. If $G$ is a tree, then $U(G) = G$; otherwise $U(G)$ is an infinite tree.
3. Suppose that $G$ is a graph without 3-cycles and 4-cycles, and $\sigma : Q_d \to G$ is a graph map for some $d \geq 1$. Then there exists a graph map $\tilde{\sigma} : Q_d \to U(G)$ such that $\sigma = u \tilde{\sigma}$.
4. For any $q \in Q_d$, the map $\tilde{\sigma}$ in (3) may be chosen so that $\tilde{\sigma}(q) = \tilde{q}$, where $\tilde{q}$ is any element of $u^{-1}(\sigma(q))$, and $\tilde{\sigma}$ is uniquely determined by that choice.

Sketch of Proof. $U(G)$ may be constructed by fixing a basepoint $v_0$ in $G$, and then defining the vertex set of $U(G)$ to be the set of paths $(v_0, v_1, \ldots, v_k)$ in $G$ that are “non-backtracking”, i.e., $v_{i-1} \neq v_{i+1}$ for $i = 1, \ldots, k-1$. Define the edges of $U(G)$ to be pairs of paths of the form $((v_0, v_1, \ldots, v_k), (v_0, v_1, \ldots, v_k, v_{k+1}))$. The covering map $u : U(G) \to G$ sends $(v_0, v_1, \ldots, v_k)$ to $v_k$. The vertex $\tilde{v}_0 = (v_0) \in U(G)$ will be called the root of $U(G)$. It is clear that $U(G)$ is a tree, and (2) is immediate.
The proof of (3) is as in Lemma 3.3, except that instead of explicit rules to extend \( \tilde{\sigma} \) along paths in \( Q_d \), we use “stars” to guide the construction. More precisely, if \( \tilde{\sigma}(v) = \tilde{x} \in U(G) \) has been defined, and \( u \) is adjacent to \( v \) in \( Q_d \), define \( \tilde{\sigma}(u) = \tilde{x} \) if \( \sigma(u) = \sigma(v) \), and otherwise, if \( \sigma(u) = v' \in E_{\sigma(v)} \), define \( \tilde{\sigma}(u) \) to be the unique vertex in \( E_{\tilde{\sigma}} \) whose image under \( p \) equals \( v' \). The argument that \( \tilde{\sigma} \) is well defined is exactly the same as in Lemma 3.3. Verification of (4) is left to the reader. \( \square \)

A more general version of Lemma 4.3(3) for arbitrary covering graphs \( \tilde{G} \) appears in [11]. However, in the present paper we require only the special case where \( \tilde{G} = U(G) \), and the argument here is self-contained.

We proceed with the sequence of lemmas need to prove Theorem 4.1, always assuming that \( G \) is a finite connected graph without 3-cycles or 4-cycles. In the remainder of the proof, we will assume that \( \sigma \) is a singular \( d \)-cube, and \( \tilde{\sigma} \) has been (uniquely) constructed so that if \( q_0 = (0, 0, \ldots, 0) \in Q_d \) and \( \sigma(q_0) = x_0 \in G \), then \( \tilde{\sigma}(q_0) = \tilde{x}_0 \in u^{-1}(x_0) \) has been chosen so that \( \tilde{x}_0 \) is at least distance \( d+2 \) from the root \( \tilde{v}_0 \) of \( U(G) \).

By construction, \( U(G) \) is a discrete infinite tree. We can embed \( U(G) \) into a “continuous” tree \( U(G) \), obtained by identifying each edge in \( U(G) \) with a unit interval in \( \mathbb{R} \). Next define a metric \( d \) on \( U(G) \) by setting \( d(x, y) \) equal to the length (under the induced metric) of the unique path from \( x \) to \( y \), for all \( x, y \in U(G) \). This will allow us to compute weighted averages \( \alpha x + (1-\alpha)y \), for any \( x, y \in U(G) \) and \( \alpha \in [0, 1] \), by identifying the path from \( x \) to \( y \) in \( U(G) \) with a segment in \( \mathbb{R} \). More precisely:

**Definition 4.4.** Suppose that \( x, y \in U(G) \) and \( \alpha \in [0, 1] \). Define \( \alpha x + (1-\alpha)y \) to be the unique point \( p \) in the path from \( x \) to \( y \) such that \( d(x, p) = \alpha d(x, y) \).

Given \( \sigma : Q_d \to G \) and its extension \( \tilde{\sigma} : Q_d \to U(G) \), we will define an extension \( \tilde{\sigma}^N \) of \( \tilde{\sigma} \) to the grid \( Q_d^N = \{(a_1, \ldots, a_d) \mid 0 \leq a_i \leq N \} \), taking values in \( U(G) \). The construction is similar to the one in Section 3, using weighted averages along paths in \( U(G) \). However, verifying that \( \tilde{\sigma}^N \) is a graph map requires extra care because the computation is not necessarily being carried out within a fixed interval in \( \mathbb{R} \).

**Definition 4.5** (Definition of \( \tilde{\sigma}^N \)). Given \( \sigma : Q_d \to G \) and its lift \( \tilde{\sigma} : Q_d \to U(G) \), define \( \tilde{\sigma}^N : Q_d^N \to U(G) \) as follows.

1. For each edge in \( Q_d \) parallel to the first coordinate axis, i.e., from \((0, \epsilon_2, \ldots, \epsilon_d)\) to \((1, \epsilon_2, \ldots, \epsilon_d)\), for some sequence of \( \epsilon_i \in \{0, 1\} \), subdivide the path in \( U(G) \) from \( \tilde{\sigma}(0, \epsilon_2, \ldots, \epsilon_d) \) to \( \tilde{\sigma}(1, \epsilon_2, \ldots, \epsilon_d) \) into \( N \) pieces with \( N-1 \) equally spaced points. Map the points \((k, N\epsilon_2, \ldots, N\epsilon_d) \in \tilde{\sigma}^N, 1 \leq k \leq N-1 \), to these \( N-1 \) points in \( U(G) \).
2. Inductively, assume that values of \( \tilde{\sigma}^N \) have been assigned to all \((i-1)\)-faces of \( Q_d^N \) that are parallel to the first \( i-1 \) coordinate vectors, i.e., faces of the form \( \{(a_1, \ldots, a_{i-1}, N\epsilon_i, \ldots, N\epsilon_d) \} \), where \( \epsilon_i, \ldots, \epsilon_d \) are fixed elements of \( \{0, 1\} \) and the \( a_i \) range over all possible values in \( \{0, \ldots, N\} \). For each sequence \( a_1, \ldots, a_{i-1}, \) extend \( \tilde{\sigma}^N \) to points in the interior of the line from \((a_1, \ldots, a_{i-1}, 0, \ldots, 0) \) to \((a_1, \ldots, a_{i-1}, N, \ldots, N) \) by subdividing the segment in \( U(G) \) from \( \tilde{\sigma}(a_1, \ldots, a_{i-1}, 0, \ldots, 0) \) to \( \tilde{\sigma}(a_1, \ldots, a_{i-1}, N, \ldots, N) \) into \( N \) equal pieces, and assigning values of \( \tilde{\sigma} \) to interior points accordingly. This step assigns values of \( \tilde{\sigma}^N \) to all \( i \)-faces of \( Q_d^N \).
(3) Repeat step (2) until $i = N$.

In order to verify that $\tilde{\sigma}^N$ has the desired properties, we will need the following result, which is a generalization of Lemma 3.7.

**Lemma 4.6.** Suppose that $x, y, u, v \in \overline{U(G)}$, and suppose $d(x, y) \leq \delta$ and $d(u, v) \leq \delta$, where $\delta \leq 1$. Then for any $\alpha, 0 \leq \alpha \leq 1$, we have $d(\alpha x + (1 - \alpha)u, \alpha y + (1 - \alpha)v) \leq \delta$.

**Proof.** If $x, y, u$ and $v$ all lie on a single path in $\overline{U(G)}$, we can identify this path with an interval in $\mathbb{R}$ and, for example, the point $\alpha x + (1 - \alpha)y$ may be computed using ordinary real arithmetic. In this interval we have $x - y \in [-\delta, \delta]$ and $u - v \in [-\delta, \delta]$, which imply

$$d(\alpha x + (1 - \alpha)u, \alpha y + (1 - \alpha)v) = \alpha(x - y) + (1 - \alpha)(u - v) \in [-\delta, \delta],$$

as desired. If $x, y, u$ and $v$ do not lie on a single path, then some additional argument is needed.

Let $p = \alpha x + (1 - \alpha)u$ and $q = \alpha y + (1 - \alpha)v$, where these points are computed in $\overline{U(G)}$ as defined as in Definition 4.4, using the metric on $\overline{U(G)}$.

Since $d(x, y) \leq 1$, $x$ and $y$ must either lie on a single edge of $\overline{U(G)}$, or on two adjacent edges, and $u$ and $v$ are situated similarly. Up to obvious permutations of the labels, there are only two configurations representing the possible arrangements of $x, y, u$ and $v$ in $\overline{U(G)}$, as shown in the following diagrams.

In both diagrams, the doubled lines represent the portions of the $xu$ and $yv$ paths that overlap, and the red and green segments represent portions that do not overlap. The overlapping portion must be non-empty, but could consist of a single point.

Let $T = T(x, y, u, v)$ denote the (metric) subtree of $\overline{U(G)}$ obtained by taking the union of the paths from $x$ to $u$ and $y$ to $v$. Let $T \subseteq \mathbb{R}$ denote an interval in $\mathbb{R}$ obtained by taking the union of two intervals obtained by mapping each of the $xu$ and $yv$ paths isometrically into $\mathbb{R}$, in such a way that the overlapping portions coincide. For example, $T$ might look like this, with $p$ and $q$ included:

In this picture, only the segment represented by the doubled lines is guaranteed to be isometric to the corresponding segment in $\overline{U(G)}$.

If $p$ and $q$ both lie in doubled portion (as they do in the picture above), the calculation in (9) applies, and the desired inequality follows. In fact, (9) applies unless $p$ and $q$ both lie in the red region or both lie in the green region, since in all other cases the relevant components of (9) in $T$ may be computed using real arithmetic in $T$.

The remaining cases are easy to deal with, since if $p$ and $q$ both lie in the red region or the green region, then $d(p, q)$ is bounded by $d(x, y)$ or $d(u, v)$, as
appropriate. By assumption, both of these distances are \( \leq \delta \), and the conclusion follows. \( \square \)

**Definition 4.7** (Analog of Definition 3.8). Define maps \( \lfloor \cdot \rceil : U(G) \to U(G) \) (rounding), and \( [\cdot] : U(G) \to G \) (residue), as follows:

1. If \( \bar{x} \in U(G) \), and \( \bar{x} \) lies in an edge \( e \), define \( \lfloor \bar{x} \rfloor \) to be the vertex of \( e \) closest to the root \( v_0 \).
2. If \( \bar{x} \in U(G) \), define \( [\bar{x}] = u(\bar{x}) \), the projection of \( \bar{x} \) onto \( G \).

**Lemma 4.8.** If \( \bar{x}, \bar{y} \in \overline{U(G)} \) and \( d(\bar{x}, \bar{y}) \leq 1 \), then \( d(\lfloor \bar{x} \rfloor, \lfloor \bar{y} \rfloor) \leq 1 \). If \( \bar{x}, \bar{y} \in U(G) \) and \( d(\bar{x}, \bar{y}) \leq 1 \), then \( d([\bar{x}], [\bar{y}]) \leq 1 \).

**Proof.** These statements are elementary. \( \square \)

**Definition 4.9** (Analog of Definition 3.10). If \( \sigma : Q_d \to G \) and \( \tilde{\sigma}^N : Q_d^N \to \overline{U(G)} \) is the map defined above, define \( [\tilde{\sigma}^N] : Q_d^N \to G \) by

\[
[\tilde{\sigma}^N](a_1, \ldots, a_d) = \lfloor [\tilde{\sigma}^N(a_1, \ldots, a_d)] \rfloor.
\]

Finally, define \( S^N(\sigma) \) to be the sum (in \( C_d(G) \)) of the small subcubes appearing in \( [\tilde{\sigma}^N] \).

The following corollary is easily proved using Lemma 4.6 and Lemma 4.8.

**Corollary 4.10** (Analog of Corollary 3.11). (1) \([\tilde{\sigma}^N]\) is a graph map from \( Q_d^N \) to \( G \).

(2) If \( n \geq d \), then every small subcube appearing in \([\tilde{\sigma}^N]\) has at most two labels.

In other words, \( S^N : C_d(G) \to C_d^{(2)}(G) \).

To complete the proof of Theorem 4.1 we must construct maps \( h_d : C_d(G) \to C_{d+1}(G) \) and \( h_{d-1} : C_{d-1}(G) \to C_{d}(G) \) and show that they define a chain homotopy. To establish part (1) of Theorem 4.1 the constructions of \( h_d \) and \( h_{d-1} \) in Section 3 carry over with almost no change. The only non-trivial step is showing that \( h_d \) and \( h_{d-1} \) are defined by graph maps on the generators of \( C_d(G) \) and \( C_{d-1}(G) \), but this is a straightforward consequence of Lemma 4.6 and Lemma 4.8. Once these details are established, the arguments proving parts (2) and (3) carry over as well, and the proof of Theorem 4.1 is complete. \( \square \)

5. NON-VANISHING HOMOLOGY IN HIGH DIMENSIONS

In this section we will construct an infinite sequence of graphs \( \{G_d\}_{d \geq 0} \) such that \( H_d^{cub}(G_d) \neq 0 \) for all \( d \). The construction is inspired by [3] Definition 5.2 but includes some additional (necessary) details.

In the following definition, if \( G \) and \( H \) are graphs, \( G \sqcap H \) denotes the graph with vertex set \( V(G) \times V(H) \) and edges \( \{(g_1, h_1), (g_2, h_2)\} \), where either \( g_1 = g_2 \) and \( \{h_1, h_2\} \in E(H) \) or \( h_1 = h_2 \) and \( \{g_1, g_2\} \in E(G) \).

**Definition 5.1.** Let \( G \) be a graph.

1. If \( N \) is a positive integer, let \( G^{\times N} \) denote the graph \( (G \sqcap I_N)/\sim \), where \( I_N \) is the path with vertex set \( \{0, \ldots, N\} \) and \( \sim \) identifies each of the subgraphs \( \{0\} \times G \) and \( \{N\} \times G \) to single points, denoted \( \emptyset \) and \( \N \), respectively.
2. Define the sequence \( \{G_d\}_{d \geq 1} \) by setting \( G_1 = G \), and \( G_{d+1} = G_d^{\times (d+3)} \) for \( d \geq 1 \).
Theorem 5.2. If $G$ is any graph, and the sequence $\{G_d\}_{d \geq 1}$ is constructed as in Definition 5.1 then $H_{\text{Cube}}^{G_{d+1}}(G) = H_{\text{Cube}}^{G_d}(G)$ for all $d \geq 1$.

For example, if $G = G_1 = Z_5$, then for the graph $G_2$ shown in Figure 1, we have $H_{\text{Cube}}^{G_2}(G_2) = R$.

The proof of Theorem 5.2 depends on the following lemma.

Lemma 5.3. If $G$ is any graph, and $\sigma : Q_d \to G \times N$ is a singular $d$-cube, then if $N \geq d + 1$, the image of $\sigma$ cannot contain both 0 and $N$.

Proof. Since $\sigma$ is a graph map, $d(\sigma(x), \sigma(y)) \leq d(x, y)$ for all $x, y \in Q_d$. Since $\text{diameter}(Q_d) = d$ and $d(0, N) = N$ in $G \times N$, the result follows.

Proof of Theorem 5.2. Fix $d \geq 1$, and define $A = G_{d+1} - 0$ and $B = G_{d+1} - d + 3$.

It follows from Lemma 5.3 that

$C_k(G_{d+1}) = C_k(A) + C_k(B)$

for all $k \leq d + 2$. This enables us to derive a segment of the Mayer-Vietoris sequence for $A, B$ and $G_{d+1}$. More precisely, for $k = d, d + 1, d + 2$ we have short exact sequences

$$0 \to C_k(A \cap B) \xrightarrow{i} C_k(A) \oplus C_k(B) \xrightarrow{j} C_k(G_{d+1}) \to 0$$

where $i(x) = (x, -x)$ for all $x \in A \cap B$ and $j(x, y) = x + y$ for all $x \in A, y \in B$.

Using standard arguments (e.g. [12 §2.1]) one obtains the following exact sequence in homology:

$$H_{\text{Cube}}^{C_{d+1}(A)} \oplus H_{\text{Cube}}^{C_{d+1}(B)} \xrightarrow{j'} H_{\text{Cube}}^{C_{d+1}(G_{d+1})} \xrightarrow{i'} H_{\text{Cube}}^{C_{d}(A \cap B)} \xrightarrow{i} H_{\text{Cube}}^{C_{d}(A)} \oplus H_{\text{Cube}}^{C_{d}(B)}.$$
map $\Delta$ may be defined as follows: if $[x] \in \mathcal{H}^{\text{Cube}}(C_{d+1}(G_{d+1}))$, write $x = y_A + y_B$, where $y_A \in C_{d+1}(A)$ and $y_B \in C_{d+1}(B)$. Then $\Delta[x] = [\partial y_A] = [-\partial y_B] \in C_d(A \cap B)$.

It follows from results in [4, §4] that $\mathcal{H}^{\text{Cube}}(C_k(A)) = \mathcal{H}^{\text{Cube}}(C_k(B)) = (0)$ for $k \geq 1$, since $A$ and $B$ are contractible (in the sense of [5]) to single-point graphs. Furthermore, $\mathcal{H}^{\text{Cube}}(C_d(A \cap B)) \approx \mathcal{H}^{\text{Cube}}(C_d(G_d))$ since $G_d$ is a deformation retraction (in the sense of [4, §4]) of $A \cap B$. Hence [11] reduces to the exact sequence

$$0 \xrightarrow{j_*} \mathcal{H}^{\text{Cube}}(C_{d+1}(G_{d+1})) \xrightarrow{\Delta} \mathcal{H}^{\text{Cube}}(C_d(G_d)) \xrightarrow{i_*} 0,$$

and the proof is complete. \hfill $\square$

We do not know if our construction of $G_{d+1}$ in Definition 5.1 is “tight”, i.e. whether Theorem 5.2 would hold if we defined $G_{d+1} = G_{d+1}^{\times N}$ for some smaller value of $N$. Our proof depends on the choice of $N = d + 3$ but, for example, computation shows that if $G = G_1 = Z_5$, then the graph $G_2' = G_1^{3,3}$ also has homology equal to $R$ in dimension 2. It would be interesting to explore whether $d + 3$ in Definition 5.1 could be reduced to $d + 2$ in general.

6. Final Remarks

The main results in this paper (and much more) could be proved more easily if we had a complete Mayer-Vietoris theory at our disposal. As in classical treatments (e.g. [12, 15]), the main tool in would be a “covering lemma” stating that if a graph $G$ can be covered (set-theoretically) by a family of subgraphs $\mathcal{K} = \{K_i\}$ satisfying appropriate “neighborhood” conditions, then $\mathcal{H}^{\text{Cube}}(\mathcal{C}(G)) = \mathcal{H}^{\text{Cube}}(\mathcal{C}^\mathcal{K}(G))$, where

$$C_d^\mathcal{K} = \{ \sigma \in C_d(G) \mid \text{Im}(\sigma) \subseteq K_i \text{ for some } i \}.$$

In fact for graphs $G$ with no 3-cycles or 4-cycles, the subdivision techniques in Sections 3 and 4 of this paper provide such a theory, but it is of little independent value because all homology groups are trivial in dimension $d \geq 2$.

It is tempting to speculate that for arbitrary graphs, the covering space arguments in Section 4 might be modified and/or extended to prove something like the following:

**Conjecture 6.1.** Let $G$ be a graph, and let $\mathcal{K} = \{K_i\}$ be a covering of $G$ by subgraphs such that every edge, 3-cycle, and 4-cycle of $G$ is contained in some $K_i$. Then $\mathcal{H}^{\text{Cube}}(G) \approx \mathcal{H}^{\text{Cube}}(\mathcal{C}^\mathcal{K}(G))$.

However, this conjecture is false: for example, if $G = Q_3$, the 3-cube, then $\mathcal{H}_2^{\text{Cube}}(G) = (0)$ by Corollary 4.3 of [4]. On the other hand, if $\mathcal{K}$ is the covering of $G$ by its six quadrilateral faces, then direct computation (omitted here) shows that $\mathcal{H}_2^{\text{Cube}}(\mathcal{C}^\mathcal{K}(G)) = R$.

While it falls short of providing a Mayer-Vietoris theory for $\mathcal{H}^{\text{Cube}}(G)$, the following proposition does help identify what $\mathcal{H}^{\text{Cube}}(\mathcal{C}^\mathcal{K}(G))$ is computing, and may be of independent interest.

**Proposition 6.2.** Let $G$ be a graph, and suppose that $\mathcal{K}$ is the covering of $G$ by its edges, 3-cycles, and 4-cycles. Then $\mathcal{H}^{\text{Cube}}(\mathcal{C}^\mathcal{K}(G)) \approx \mathcal{H}^{\text{Sing}}(G^*)$, where the latter denotes the singular homology of the cell complex $G^*$ obtained from $G$ (considered as a 1-complex) with 3- and 4-cycles filled in as 2-dimensional cells.
Proof. For the proof it will be convenient to consider the cellular homology \( H_{\text{Cell}}(G^*) \) instead of \( H_{\text{Sing}}(G^*) \). By [12, Theorem 2.35] \( H_{\text{Sing}}(X) \approx H_{\text{Cell}}(X) \) for any CW-complex. In particular, it suffices to show that \( H_{\text{Cube}}(K^*) \approx H_{\text{Cell}}(G^*) \).

Let \( K^* \) be the cover of \( G^* \) by its edges, triangles, and quadrangles. Note that \( G^* \) has a natural CW-structure and each element of the cover is a closed subcomplex of \( G^* \). First, by construction there is a natural bijection between \( K \) and \( K^* \). For any non-empty subset \( \sigma \subseteq K \) let \( K_\sigma \) be the intersection of the elements of \( \sigma \). Correspondingly, for any non-empty subset \( \sigma^* \subseteq K^* \) let \( K_{\sigma^*} \) be the intersection of the elements of \( \sigma^* \).

Claim 1: For any non-empty \( \sigma \subseteq K \) and the corresponding \( \sigma^* \subseteq K^* \) we have
\[
H^\text{Cube}_*(K_\sigma) \approx H^\text{Cell}_*(K_{\sigma^*}).
\]

Moreover, both are trivial in homological dimensions \( \geq 1 \).

Proof of Claim 1: For \( \sigma \subseteq K \) with \( |\sigma| > 1 \), \( K_\sigma \) and \( K_{\sigma^*} \) are both either empty, one or two points, or a path of length 1 or 2. On these graphs and spaces the discrete cubical and cellular homology theories coincide and are trivial in dimensions \( \geq 1 \).

For \( \sigma \subseteq K \) with \( |\sigma| = 1 \), either both \( K_\sigma \) and \( K_{\sigma^*} \) are edges, \( K_\sigma \) is a triangle graph and \( K_{\sigma^*} \) is a solid triangle, or \( K_\sigma \) is a quadrangle graph and \( K_{\sigma^*} \) is a solid quadrangle. The cellular homology groups of a solid quadrangle and a solid triangle are trivial in homological dimension \( \geq 1 \), as are the discrete cubical homology groups of a quadrangle and a triangle graph. This proves the claim.

Claim 2: Let \( \tau \subseteq \sigma \subseteq K \). Then the induced maps
\[
H^\text{Cube}_0(K_\sigma) \to H^\text{Cube}_0(K_\tau) \quad \text{and} \quad H^\text{Cell}_0(K_{\sigma^*}) \to H^\text{Cell}_0(K_{\tau^*})
\]
are either both isomorphisms, both 0 maps, or both are projections of a rank 2 onto a rank 1 homology group.

Proof of Claim 2: It follows from an analysis of the proof of the previous claim that all homology groups in dimension 0 are of rank 1 unless the intersection is empty (in which case it is 0) or the intersection is a two point set (in which case it is of rank 2). Now the assertion follows by inspecting the cases.

Let \( N(K) \) be the nerve of the covering \( K \), that is, the simplicial complex whose \( p \)-simplices are the subcollections of \( K \) of size \( p + 1 \) with non-empty intersection. For \( p \geq 0 \), let \( N^{(p)}(K) \) denote the set of faces of dimension \( p \) in \( N(K) \). Note that by the above arguments the nerve is the same for \( K \) and \( K^* \). From the given data we build, in the usual way (see, e.g., [8, Chap. 7]), two double complexes
\[
C^\text{Cube}_{p,q}(G) = \bigoplus_{\sigma \subseteq N^{(p)}(K)} C^\text{Cube}_q(K_\sigma)
\]
and
\[
C^\text{Cell}_{p,q}(G) = \bigoplus_{\sigma \subseteq N^{(p)}(K)} C^\text{Cell}_q(K_{\sigma^*})
\]
where for \( \bullet \in \{ \text{Cube, Cell} \} \) the vertical differential \( C^\bullet_{p,q} \to C^\bullet_{p,q-1} \) is the differential in the cubical or cellular homology theory, and the horizontal differential \( C^\bullet_{p,q} \to C^\bullet_{p-1,q} \) is induced by the inclusion maps combined with the sign of the differential of the nerve, seen as a simplicial complex. More precisely, let \( \sigma \in N^{(p)}(K) \), \( \tau \subseteq \sigma \) and \( |\tau| \in N^{(p-1)}(K) \). It follows that \( K_\sigma \subseteq K_\tau \) and \( \tau = \sigma \setminus \{ j \} \) for some \( j \in \sigma \). Thus \( \tau \) appears in the simplicial boundary of \( \sigma \) with some sign \( \epsilon_{\sigma,\tau} \). Now the
differential $C_{p,q}^\bullet \to C_{p-1,q}^\bullet$ is the sum of the maps $C_{p,q}^\bullet(K_\tau) \to C_{p-1,q}^\bullet(K_\tau)$, for all $\tau \subseteq \sigma$, $|\tau| \in N^{(p-1)}(K)$, induced by inclusion and multiplied by $\varepsilon_{\sigma,\tau}$.

The two double complexes yield with respect to the vertical differential a spectral sequence (see, e.g., [8, Chapter 7]) with $E^1$ page given by $E^1_{p,q}(\text{Cube}) = \bigoplus_{\sigma \in N^p(K)} H^q_{\text{Cube}}(K_\sigma)$ and $E^1_{p,q}(\text{Cell}) = \bigoplus_{\sigma \in N^p(K)} H^q_{\text{Cell}}(K_\sigma)$. From the first claim we already know that $E^1_{p,q}(\text{Cube}) \approx E^1_{p,q}(\text{Cell})$ and $E^1_{p,q}(\text{Cube}) = E^1_{p,q}(\text{Cell}) = 0$ for $q \geq 1$.

Next we consider the differentials of the $E^1$ pages in both cases. Note that for $\bullet \in \{\text{Cube, Cell}\}$ the differential of $E^1_{p,q}(\bullet) \to E^1_{p-1,q}(\bullet)$ is induced as follows. Consider $\sigma \in N^p$ and let $\tau_0, \ldots, \tau_p$ be its maximal faces. Then we have a map in homology

$$H^q_{\sigma}(\sigma) \to \bigoplus_{i=0}^{p-1} H^q_{\tau_i}(\tau_i)$$

induced by the sum of the inclusion maps weighted with the sign of the simplicial differential. This map in turn induces the differential on $E^1_{p,q}(\bullet)$. By the second claim the maps in homology (if they are not trivial) coincide for both theories. As a consequence the differentials on the $E^1$-pages are the same and so $E^2_{p,q}(\text{Cube}) \approx E^2_{p,q}(\text{Cell})$.

Since $E^1_{p,q}(\text{Cube}) = E^1_{p,q}(\text{Cell}) \neq 0$ implies $q = 0$ the same holds true for $E^s_{p,q}(\bullet)$ and $s \geq 2$. But the differential on the $s$th page maps $E^s_{p,q}(\bullet) \to E^s_{p-s,q+1-s}(\bullet)$. This shows that the differential of the $s$th page is trivial for all $s \geq 2$. Thus both sequences have the same limit and the limit is obtained on the $E^2$-page, with non-zero entries concentrated on the bottom row.

For any double complex $\{C_{p,q}\}$, one can construct not only a spectral sequence $\{E^r\}$, but also a second (transposed) spectral sequence $\{\tilde{E}^r\}$ using horizontal differentials (instead of vertical) to define $\tilde{E}^1$, and then constructing subsequent pages by the usual rules. In this case, it is well known (e.g. [17 Chap. 5]) that both $\{E^r\}$ and $\{\tilde{E}^r\}$ compute the same homology, namely, the homology of the total complex $\text{TC}_d = \bigoplus_{p+q = d} C_{p,q}$.

In our situation, it can be shown (see [8 Chap. 7] for an example of the argument) that $\{E^r(\text{Cube})\}$ and $\{\tilde{E}^r(\text{Cell})\}$ both converge on the second page $\tilde{E}^2$, with non-zero entries concentrated in the first column. In that column we have

$$\tilde{E}^2_{0,d}(\text{Cube}) \approx H^d_{\text{Cube}}(C^*(G)) \quad \text{and} \quad \tilde{E}^2_{0,d}(\text{Cell}) \approx H^d_{\text{Cell}}(G^*)$$

for all $d \geq 0$. Combining all of the above information, we obtain, for all $d \geq 0$,

$$H^d_{\text{Cube}}(C^*(G)) \approx \tilde{E}^2_{0,d}(\text{Cube}) \approx E^2_{d,0}(\text{Cube})$$

$$\approx E^2_{d,0}(\text{Cell}) \approx \tilde{E}^2_{0,d}(\text{Cell}) \approx H^d_{\text{Cell}}(G^*)$$

as claimed, and the proof is complete. \hfill \Box

As a somewhat non-trivial illustration of Proposition 6.2 let $G$ be the 1-skeleton of an octahedron, as illustrated in Figure 2. Here $K$ is the covering of $G$ consisting of 12 edges, 8 triangles, and 3 quadrangles. Computation (omitted) shows that $H^2_{\text{Cube}}(C(G)) = H^2_{\text{Sing}}(G^*) = R^4$. On the other hand, it follows from Corollary 4.6 in [3] (or can be shown directly) that $H^2_{\text{Cube}}(C(G)) = (0)$.

Our results and observations highlight the special role played by graphs without 3- and 4-cycles, and indeed, for these graphs, the discrete and ordinary singular
cubical homology theories agree completely. It would be interesting to establish
the precise connections between the two theories for more general graphs. While
results like Proposition 6.2 might provide information about $\mathcal{H}^{\text{Cube}}(C^K(G))$ for a
covering $K$, they do not give us information about $\mathcal{H}^{\text{Cube}}(G)$ directly, and a richer
theory is needed to help bridge this gap.

7. Acknowledgements

We are grateful to Eric Babson for several comments that helped clarify our
proofs, especially of Corollary 3.3 and Lemma 3.5.
