ABSTRACT

Context. The knowledge of the present-day mass function of young clusters and the mass of their coolest substellar members is essential to clarify the brown dwarf formation mechanism, which still remains a matter of debate. Aims. We searched for isolated planetary-mass T-dwarfs in the ~3 Myr old Serpens Core cluster. Methods. We performed a deep imaging survey of the central part of this cluster using the WIRCam camera at the CFHT. Observations were performed through the narrow-band CH4off and CH4on filters, to identify young T-dwarfs from their 1.6 μm methane absorption bands, and the broad-band JHKs filters, to better characterize the selected candidates. We complemented our WIRCam photometry with optical imaging data from MegaCam at CFHT and Suprime-Cam at the Subaru telescope and mid-infrared flux measurements from the Spitzer “core to disk” (c2d) Legacy Survey. Results. We report four faint T-dwarf candidates in the direction of the Serpens Core with CH4on–CH4off above 0.2 mag, estimated visual extinction in the range 1–9 mag and spectral type in the range T1–T5 based on their dereddened CH4on–CH4off colors. Comparisons with T-dwarf spectral models and optical to mid-infrared color–color and color–magnitude diagrams, indicate that two of our candidates (ID 1 and 2) are background contaminants (most likely heavily reddened low-redshift quasars). The properties of the other two candidates (ID 3 and 4) are consistent with them being young members of the Serpens Core cluster, although our analysis can not be considered conclusive. In particular, ID 3 may also be a foreground T-dwarf. It is detected by the Spitzer c2d survey but only flux upper limits are available above 5.8 μm and, hence, we can not assess the presence of a possible disk around this object. However, it presents some similarities with other young T-dwarf candidates (S Ori 70 in the Orionis cluster and CFHT_J0344+3206 in the direction of IC 348). If ID 3 and 4 belong to Serpens, they would have a mass of a few Jupiter masses and would be amongst the youngest, lowest mass objects detected in a star-forming region so far. Key words. stars: formation – brown dwarfs – ISM: clouds – ISM: individual objects: Serpens Core – stars: low-mass

1. Introduction

Understanding the brown dwarf (BD) formation mechanism is a key point to assess what determines and which is the minimum mass for star formation. Although two decades have passed since the first unambiguous observations of BDs (Rebolo et al. 1995; Nakajima et al. 1995), this issue is still under debate. According to the star formation theory, the minimum mass for star formation is set by the so called mass fragmentation limit, i.e. the mass at which one object cannot contract further because the radiated heat prevents it to collapse further. This limit is of the order of a 5–10 MJ (Low & Lynden-Bell 1976; Rees 1976) and may be lower (~1 M1) in the presence of magnetic fields (Boss 2001; Boyd & Whitworth 2005). Observationally, several young star forming regions have been probed to faint magnitudes at both optical and near-infrared wavelengths to look for a possible cut-off at the low-mass end of the mass function and the results significantly vary from region to region. A possible cut-off below ~6 M1 up to 20 M1 have been reported in NGC 1333 (e.g., Scholz et al. 2009, 2012). Moreover, there is no universal agreement on the behavior of the mass function over this cut-off. A search for T-dwarfs in IC 348 by Burgess et al. (2009) suggests that an extrapolation of the log-normal mass function (Chabrier 2003) may hold in the substellar and planetary-mass regimes. A similar study in the Upper Sco association favors a turn-down in the mass function below 10 M1 (Lodieu et al. 2011). In the Pleiades Casewell et al. (2007) reported several L/T-type candidates with masses as low as 10 M1J, implying that the slope of the mass function in this mass regime agrees, within the uncertainties, with the values inferred from earlier studies at higher masses (Dobbie et al. 2002; Moraux et al. 2003; Lodieu et al. 2007; Casewell et al. 2007). Finally, Kirkpatrick et al. (2012) find tantalizing hints that the number of BDs in the field continues to rise from late-T to early-Y.

To address these questions, a large observing key-program (PI. J. Bouvier) was conducted at the Canada France Hawaii Telescope (CFHT) aimed at characterizing the stellar population of nearby star forming regions using the Wide Field IR Camera (WIRCam). One of the main objectives of this program is to look for the lowest mass members of these clusters and investigate the cut-off at the low mass end of the mass function, using a technique based on narrow-band methane imaging (e.g., Burgess et al. 2009).
In this paper, we report the results of this observing program in the Serpens Core cluster, specifically focusing on the methane filters imaging to search for young T-dwarfs candidates. The Serpens Core region is an example of a very young, deeply embedded ($A_V \approx 40$ mag) cluster, containing a high percentage of protostars (Davis et al. 1999; Testi et al. 2000; Kaas et al. 2004; Eiroa et al. 2006; Harvey et al. 2007; Winston et al. 2007). With an age between 2 and $\sim 6$ Myr (Winston et al. 2009; Oliveira et al. 2009) and a distance estimated between 260 $\pm$ 37 pc (Stražys et al. 2003) and 415 $\pm$ 5 pc (Dzib et al. 2010), the Serpens cloud core is one of the nearest regions of clustered star formation to the Sun. Therefore, it is an excellent candidate for study as it is close enough to both resolve the individual members and detect the lowest mass members to below the hydrogen-burning limit. Throughout this paper, we assume a typical age of 3 Myr (Winston et al. 2009) for the Serpens Core cluster and the minimum distance of 260 $\pm$ 37 pc (Stražys et al. 2003)$^1$. The region is also particularly interesting for BD studies because only a few dedicated searches have been reported in the literature. The first young BD in Serpens was discovered by Lodieu et al. (2002) and the cluster substellar population count so far about 3 spectroscopically confirmed BDs (Lodieu et al. 2002; Shirron et al. 2011) and 40 BD candidates, a considerable fraction of which still surrounded by prominent accretion disks (Eiroa et al. 2006).

Canonical approaches on BD studies and related issues (see, e.g., Jayawardhana et al. 2003) rely on the identification and spectral classification of BDs. However, optical/near-infrared (IR) spectroscopy (see, e.g., McLean et al. 2003; Geballe et al. 2002) has proved impossible for very faint distant BDs with current telescopes and very time-consuming for large BD samples. To overcome these limitations, new BD classification methods have been devised on the basis of near-IR broad-band (see, Marmo 2007, and references therein) and narrow-band imaging that targets unique molecular features of L and T dwarfs, in particular, water and methane bands (see, e.g., Gorlova et al. 2003; Mainzer et al. 2004; Spezzi et al. 2011). These techniques are equivalent to extremely low-resolution spectroscopy and can be confidently applied for statistical purposes, e.g., to detect and classify bona fide BDs in large imaging surveys. Our search for T-dwarfs in Serpens is based on narrow-band methane ($\text{CH}_4$) imaging. We target, in particular, the $\text{CH}_4$ absorption band centered at 1.66 $\mu$m, which forms in the atmosphere of objects cooler than $T_{\text{eff}} \lesssim 1200$ K (defining the L/T dwarf boundary; Burrows et al. 2006). This technique has been successfully applied to a search for T-dwarfs in the young IC 348 cluster (Burgess et al. 2009).

This paper is organized as follows. Section 2 describes the WIRCam observations in the Serpens Core and the catalog extraction procedure. In Sects. 3, 4 we use this catalog to identify possible T-dwarfs on the basis of methane absorption bands and estimate their intrinsic properties ($T_{\text{eff}}, A_V$, etc.). In Sect. 5 we investigate the nature of our T-dwarfs candidates using complementary near to mid-IR data and T-dwarf spectral models. The conclusions of this work are given in Sect. 6.

### 2. Observations and data reduction

The imaging observations presented in this work were obtained as part of a large CFHT key program (08AF98) aimed at the characterisation of the low-mass population of several young star-forming regions (P.J. J. Bouvier). The data were obtained in queue-scheduled observing mode between 20 April and 19 May 2008 using the WIRCam at CFHT. The WIRCam consists of four Hawaii-II-2RG $2048 \times 2048$ array detectors with a pixel scale of 0.3$''$ or 0.15$''$ with microdithering (Puget et al. 2004). The four detectors are arranged in a $2 \times 2$ pattern, with a total field of view of 21.5 $''$ x 21.5 $''$ and small gaps of 45$''$ between adjacent chips. The average CCD read-out noise and gain are 30 e- and 3.8 e-/ADU, respectively.

In this paper, we focus on the observations of the Serpens Core cluster obtained through the $\text{CH}_4$ ($\lambda_c = 1.58 \mu$m, $\Delta \lambda = 0.1 \mu$m) and $\text{CH}_4$ ($\lambda_c = 1.69 \mu$m, $\Delta \lambda = 0.1 \mu$m) filters, along with observations through the $JHK_s$ broad-band filters obtained using micro-dithering. A single WIRCam pointing centered at RA = 18$^h$29$^m$57$^s$ and Dec = +01$^\circ$13$'$08" was sufficient to cover the Serpens Core cluster. Each tile in each filter was observed using a 7-point dithering pattern selected to fill the gaps between detectors and accurately subtract the sky background. Exposure times, seeing and air mass conditions are summarized in Table 1.

| Field       | Date (d/m/y) | Filter | $T_{\text{exp}}$ (s) | Seeing (" ) |
|-------------|--------------|--------|---------------------|-------------|
| Serpens Core| 17-19/05/2008| $\text{CH}_4$on | 2520 | 0.6 |
|             | 20/04/2008   | Off    | 7560 | 0.6 |
|             | 20/04/2008   | $J$    | 8405 | 0.7 |
|             | 20/04/2008   | $H$    | 1405 | 0.7 |
|             | 20/04/2008   | $K_s$  | 1405 | 0.7 |

1 This choice is appropriate because we use the distance to Serpens to estimate the lower limit to the interstellar extinction towards the cloud (see also Sect. 4).

2 For further details, we defer the reader to the WIRCam webpage: http://www.cfht.hawaii.edu/Instruments/Imaging/WIRCam/IiwiVersion1Doc.html#Part5.
A further check/refinement of the extracted $JHK_s$ magnitudes was performed using 2MASS photometry for the brightest stars in the field, as is described in the next section (i.e., Sect. 2.1). Images in the methane filters have no external photometric calibration and the CH$_{4 \text{off}}$ and CH$_{4 \text{on}}$ magnitudes are given here on an arbitrary albeit internally consistent scale, so that $H$-CH$_{4 \text{off}} = H$-CH$_{4 \text{on}} = 0$ for unreddened field dwarfs.

2.1. Photometric catalog

The source extraction and photometry were performed by using a combination of SExtractor (Bertin & Arnouts 1996) and PSFEx (Bertin 2011). SExtractor extracts well defined stellar-like objects, which are used by PSFEx to compute a point spread function (PSF) model that is allowed to vary with position on the detector. Then, SExtractor uses this PSF model to accurately extract and measure the photometry of all the sources detected on the image.

T-dwarf candidates are expected to be fainter and, hence, possibly missed in the CH$_{4 \text{on}}$ image because of their CH$_4$ absorption. Thus, we first perform the source extraction on the CH$_{4 \text{off}}$ image and then use this catalog as input list when running SExtractor on the CH$_{4 \text{on}}$ image. To ensure the detection of all the faint sources present in the images the extraction criteria used are not too stringent. An object is extracted if it complies with the requirement to have three contiguous pixels (DETECT_MINAREA = 3) with fluxes 1.5 times above the background variation (DETECT_THRESH = ANALYSIS_THRESH = 1.5). In order to minimize the number of spurious detections, the SExtractor cleaning efficiency parameter was set to the maximum value (CLEAN_PARAM = 1). An inspection of the images and detections showed that all the objects seen by eye are detected. However, this visual inspection showed that a significant fraction of blended sources was missed. A higher selection threshold (DETECT_THRESH = ANALYSIS_THRESH = 5) allowed us to recover those sources and we created a final master catalog combining the results of the two runs and containing ~130 000 objects. The summary of saturation limits and limiting magnitudes, after cleaning for saturated objects and obvious spurious detections/artifacts (i.e. SExtractor FLAGS $\leq$ 2), is given in Table 2. The approximate completeness limit in each filter was derived as for the CH$_{4 \text{off}}$ image. The completeness limits in each filter were calculated using an arithmetic mean completeness limit, corresponding to the astrometric accuracy of our images (see Sect. 2).

| Filter  | Saturation limit | Mag$_{\text{off}}$ | Mag$_{\text{on}}$ | Completeness limit |
|---------|------------------|------------------|------------------|-------------------|
| CH$_{4 \text{off}}$ | 13.0 | 20.1 | 20.9 | 19.5 |
| CH$_{4 \text{on}}$ | 13.5 | 20.6 | 21.3 | 19.5 |
| $J$ | 13.5 | 20.8 | 21.5 | 20.5 |
| $H$ | 12.5 | 19.0 | 19.8 | 19.0 |
| $K_s$ | 12.5 | 18.6 | 19.3 | 18.5 |

3. T-dwarf candidate selection

As demonstrated by Burgess et al. (2009), the flux ratio between the CH$_{4 \text{on}}$ and CH$_{4 \text{off}}$ filters gives a good measure of the strength of the methane absorption in T-dwarfs. Specifically, the CH$_{4 \text{on}}$ filter probes the CH$_4$ absorption band centered at ~1.66 $\mu$m and typical of T-dwarfs, while the CH$_{4 \text{off}}$ filter covers a wavelength range relatively featureless in T-type objects and, hence, can be used as the primary continuum filter.

As shown by Burgess et al. (2009) in their Fig. 2, the CH$_{4 \text{on}}$-CH$_{4 \text{off}}$ color in the CFHT methane filters is roughly equal to zero for L-type and earlier type dwarfs and smoothly increases towards later spectral type, so that T-dwarfs have colors above ~0.1. Fig. 2 shows the CH$_{4 \text{on}}$-CH$_{4 \text{off}}$ diagram for point-like objects detected in the observed area in Serpens Core. We use this diagram to select T-dwarf candidates following the steps described below:

- Most of the stars in our field have spectral type earlier than L, as demonstrated by the over-density of points at CH$_{4 \text{on}}$-CH$_{4 \text{off}} = 0$ in Fig. 2. We use the median CH$_{4 \text{on}}$-CH$_{4 \text{off}}$ color of these stars as a function of the CH$_{4 \text{off}}$ magnitude to define the reference template with respect to which the CH$_4$ absorption feature is sought. The continuous line and
Fig. 1. Left panels: photometric errors as a function of PSF magnitudes and relative exponential fit (continuous line) for all the point-like sources detected in the CH$_{4}$off, CH$_{4}$on and $JHK_{S}$ images. Right panels: number of detection as a function of magnitude. The line shows the linear fit to the histogram points used to find the turning point of the distribution, indicating our completeness limit.

The line-filled area in Fig. 2 show the median locus of field stars and their dispersion ($\sigma$), respectively.

- We consider the photometric uncertainty on the CH$_{4}$on-CH$_{4}$off color ($\delta = \sqrt{\Delta CH_{4}on^2 + \Delta CH_{4}off^2}$) and select a first sample of T-dwarf candidates by considering all those objects with (CH$_{4}$on-CH$_{4}$off)-$\delta$ color exceeding that of the median locus of field stars by more than 3$\sigma$. The objects just below this limit could still be early T-dwarfs but it would be more difficult to extract them because of photometric errors. With this criterion ~200 sources were selected.

- This sample was visually inspected on both the CH$_{4}$off and CH$_{4}$on images and the $JHK_{S}$ images. Most of the objects turned out to be nebulous detections, ghosts or detector cross-talk, spurious detections/artifacts in the vicinity of saturated objects or image edges. Thus, the initial sample was reduced to a shortlist of only 4 point-like candidates.
Table 3. Photometry of the T-dwarf candidates.

| ID  | RA J2000 (hh:mm:ss) | Dec J2000 (dd:mm:ss) | r_{PFS} | i_{Subaru} | CH4on | CH4off | CH3on | J  | H  | Ks |
|-----|---------------------|----------------------|---------|------------|--------|--------|--------|----|----|----|
| 1   | 18:29:56.58         | +01:18:35.93         | –        | 22.98 ± 0.03 | 17.77 ± 0.05 | 18.07 ± 0.05 | 19.10 ± 0.05 | 17.71 ± 0.06 | 16.99 ± 0.05 |
| 2   | 18:29:57.64         | +01:19:40.61         | –        | 22.67 ± 0.03 | 17.61 ± 0.05 | 18.10 ± 0.05 | 18.84 ± 0.05 | 17.64 ± 0.06 | 17.07 ± 0.06 |
| 3   | 18:30:27.89         | +01:14:52.22         | –        | 23.98 ± 0.10 | 18.75 ± 0.05 | 19.16 ± 0.06 | 19.38 ± 0.06 | 19.08 ± 0.16 | 18.90 ± 0.27 |
| 4   | 18:30:37.24         | +01:18:37.68         | 23.57 ± 0.07 | 18.61 ± 0.06 | 18.84 ± 0.06 | 19.71 ± 0.07 | 18.67 ± 0.09 | 18.25 ± 0.10 |

Notes. CH4on and CH4off magnitudes are in the WIRCam system, while rJHKs photometry is given in the Vega system.

The PSF photometry of these four T-dwarf candidates in the CH4on/CH4off filters and in JHKs is listed in Table 3. Thumbsized images of the four candidates are shown in Fig. 3.

4. Reddening and spectral type estimates

Knowledge of the candidates’ extinction (A_V) is required in order to be able to estimate their spectral type and collect further information on their nature.

We do not know a priori whether our candidates are field T-dwarfs or young members of Serpens. In both cases, we cannot give accurate A_V value for each object based only on photometry, because we do not know their distance; they could be foreground objects closer than Serpens, cloud members located between 260 and 415 pc, i.e. the distance range of Serpens (see Table 2 by Dzib et al. 2010) or even being located beyond the cloud. Thus, we estimate the range of possible extinction values for each candidate as follows:

- According to the study by Chapman et al. (2009), the mid-infrared extinction law in Serpens is consistent with the Weingartner & Draine (2001) R_V = 3.1 diffuse interstellar-dust model below A_K ≤ 1 (A_V ≤ 9). We use this prescription to define the direction of the extinction vector.
- Assuming that our candidates belong to Serpens, extinction can be estimated using color–color diagrams of CH4on-CH4off versus J - H, J - Ks and H - Ks, as plotted in Fig. 4. The extinction is computed for each candidate using the extinction vector and regressing the objects back towards the 3 Myr PMS isochrone (Chabrier et al. 2000), i.e. the typical age of the Serpens cloud core population (Winston et al. 2009; Oliveira et al. 2009). The extinction values derived through this method (A_V^map) are reported in Table 4.
- Gutermuth (priv. comm.) calculated an extinction map of the Serpens Core using 2MASS data and the method explained in Gutermuth et al. (2007). This map has a spatial resolution of 25' × 25' and entirely covers the area observed by us. By comparing this map with our WIRCam images, we estimate that the crowding of our field is such that typically ~50 stars fall in the map resolution box. This number is suitable for a statistically significant estimate of A_V in the given box/direction based on the Gutermuth et al. (2007) method. Because the extinction map takes into account all the extinction occurring along the line of sight, it can be used to estimate the maximum extinction towards our candidates under the assumption that they are located beyond the Serpens cloud. Moreover, the extinction assigned to each object (A_V^map in Table 4) is the average value in a 25' box around the object itself and, as such, can be inaccurate for very young and highly embedded objects, which present peculiar extinction due to the material in their envelope/disk. In Sect. 5.2 we will see that this is not likely to be the case for our candidates. However, the average A_V value computed in a given 25' box can be still inaccurate for an object located in a specific position within the box, because of the effect of small scale differential reddening, presence of cloud filaments, etc.
- Finally, to estimate the lower limit to the extinction of our candidates, we assumed that they are foreground T-dwarfs located within 260 pc of our Sun, i.e. the minimum distance estimated for Serpens. The typical diffuse absorption is taken to be 0.7–1 mag/kpc in the Solar Neighborhood (see, e.g., Ichikawa et al. 1982). Thus, interloping field objects between our Sun and Serpens would be subject to A_V ≤ 0.2 mag extinction.

For each candidate, we considered a minimum extinction of 0 ≤ A_V ≤ 0.2 mag, the extinction occurring along the line of sight, given by the extinction map, and the extinction expected if the object belongs to the young population of Serpens (A_V^map and A_V^1Myr in Table 4, respectively) and calculated the relative dereddened CH4on-CH4off colors. We then used the CH4on-CH4off vs. spectral type calibration by Burgess et al. (2009) (see...
Fig. 3. Images of the four T-dwarfs candidates in each of the WIRCam@CFHT filter used in this work, as indicated in the labels. Each snapshot covers an area of 18″ × 15″; north is up and east to the left.

Table 4. Estimates of visual extinction, spectral type, and effective temperature for our T-dwarf candidates based on their dereddened CH₄on−CH₄off colors.

| ID  | Aᵥ(V)  | Aᵥ(3My) | Spec. type | Tₑff  |
|-----|--------|---------|------------|-------|
| 1   | 9.2    | 9.4     | T₂-T₄      | 1390-1290 |
| 2   | 7.9    | 7.1     | T₄-T₅      | 1290-1190 |
| 3   | 4.2    | 1.0     | T₃-T₄      | 1360-1290 |
| 4   | 2.8    | 5.5     | T₁-T₃      | 1390-1360 |

Notes. Aᵥ(3My) is the visual extinction when assuming that the object belongs to the 3 My old population of Serpens, while Aᵥ(V) is derived from the extinction map by Gutermuth (priv. comm.).

their Fig. 2) to estimate the spectral type range consistent with these dereddened colors. Note that the calibration relation by Burgess et al. (2009) is based on field dwarfs; the actual colors of our LT dwarfs might be slightly different because of the effects that reduced gravity has on the opacities (see, e.g., Casewell et al. 2011, and references therein).

The spectral type estimates for our candidates are reported in Table 4, together with the corresponding effective temperature range according to the calibration relation by Vrba et al. (2004).

5. On the nature of the T-dwarf candidates: are they young members of Serpens?

In this section we use color–magnitude diagrams (CMDs), color–color (CC) diagrams and spectral energy distributions (SEDs) to assess whether the optical/IR properties of our T-dwarf candidates are consistent with those of field objects or indicate the presence of IR excess emission typical of very young objects, which would in turn indicate membership to the Serpens Core cluster. This analysis is performed using our WIRCam data in combination with r and i-band imaging data from MegaCam at CFHT and Suprime-Cam at the Subaru telescope, and Spitzer imaging.

5.1. WIRCam near-IR color–magnitude and color–color diagrams

Figure 5 shows the position of our candidates on the J vs. J − K₅ CMD and the J − H vs. H − K₅ CC diagram before and after correction for interstellar reddening. In order to draw the dereddening vector for our candidates, we adopt the maximum extinction expected towards our candidates (i.e., the maximum between the Aᵥ(V) and Aᵥ(3My) value from Table 4); in this way, we display the maximum possible shift of their position in the CMD and CC diagram due to reddening effects.

We also plotted the 5 Gyr DUSTY and COND models and the confirmed field L and T dwarfs (Chiu et al. 2006; Golimowski et al. 2004; Knapp et al. 2004) to highlight the position expected for the field dwarf sequence. The locus expected for the young members of Serpens is indicated by the 3 Myr DUSTY and COND models and the young stellar object (YSO) population confirmed by the Spitzer core to disk (c2d) survey (Winston et al. 2007; Harvey et al. 2007). Finally, we plot for comparison the faint mid-T type object S Ori 70 found by Zapatero Osorio et al. (2002) towards the direction of the young σ Orionis cluster and the dereddened position of CFHT_J0344+3206, a mid-T dwarf candidate found by Burgess et al. (2009) in the direction of IC 348. The DUSTY and COND models and the positions of the field LT-dwarfs, S Ori 70 and CFHT_J0344+3206 are shifted to the minimum distance estimated for Serpens (i.e. 260 pc). Note that it is still unclear whether S Ori 70 is a field brown dwarf or a young planetary mass member of σ Orionis; however, proper motion and the near- and mid-IR colors measurements by Zapatero Osorio et al. (2008) support its membership to the cluster, with an estimated mass in the interval 2–7 M⊙.

Notes.
The position in both diagrams of two of our candidates, namely ID 1 and 2, is consistent with them being mid-T dwarfs. However, their reddened magnitudes are brighter than expected for young T-dwarfs at the distance of Serpens and, hence, they might be field objects. They suffer from significant interstellar extinction (Table 4) and therefore can not be foreground objects. As discussed by Delorme et al. (2008), the only background contaminants may eventually be high redshift quasi-stellar objects (QSO; z > 6) or heavily reddened low redshift QSOs, which appear point-like and share the same very red colors as cool dwarfs. Moreover, high redshift/heavily veiled QSOs can present a moderate methane-like absorption signal in the CH$_4$-CH$_4$$_\text{off}$ difference due to the combinations of specific redshifts and emission lines (Richards et al. 2003). In Sect. 5.2 we use additional imaging in the $i$ and Spitzer pass-bands to assess whether this is the case for ID 1 and 2.

ID 3 does not present a significant interstellar extinction and its near-IR colors are consistent with it being a field mid-T dwarf. Its position on the $J$ vs. $J-K_S$ diagram and spectral type are very similar to those of the mid-T type dwarf S Ori 70 in the $\sigma$ Orionis cluster and the T-dwarf candidate CFHT$_\text{J0344+3206}$ in the direction of IC 348. However, it is not redder than the sequence defined by field T-type dwarfs in the $J-H$ vs. $H-K_S$ CC diagram, as young objects should be. Indeed, the $K$-band flux is sensitive to gravity and it is fainter for young objects, especially for late T-dwarfs, because of the strongly reduced gravity (Zapatero Osorio et al. 2008). Since it is brighter than field objects at the distance of Serpens (Fig. 5, left panel), ID 3 may be a foreground field T-dwarf.

The interpretation of the CMD and CC diagram for candidate ID 4 is controversial, because it lies in both diagrams in a “transition region” mainly populated by field dwarfs but where faint and/or highly veiled YSOs might still be found. It cannot be a foreground object as it is significantly extincted (Table 4) and has near-IR reddened colors consistent with it being an early T-dwarf. It is brighter than field objects (Fig. 5, left panel), but this is still consistent with it being young (the larger radius of YSOs make them brighter than older objects with the same spectral type). Thus, ID 4 may be a cluster member.

It is worth noting that these very same conclusions can be drawn from the inspection of the CC diagrams involving colors in the CH$_4$ filters, which we presented in Fig. 4.

5.2. Complementary MegaCam, Suprime-Cam and Spitzer data

The Serpens Core cluster was observed on 2010-06-11 in the $r$ and $i$ bands with MegaCam (Boulade et al. 2003) at CFHT and on 2008-06-05 in the $i$-band with Suprime-Cam (Miyazaki et al. 2002), the wide field camera located at the prime focus of the Subaru Telescope. For details about these observations and the relative data reduction and calibration, we defer the reader to Bouy et al. (in prep.). In Table 3 we report the $ri$ photometry of our four T-dwarf candidates calibrated to the Vega system. Only one of our candidates (ID 4) was detected in both filters, while the remaining three objects (ID 1, 2 and 3) were detected only in the $i$-band.

We also searched for possible mid- to far-IR flux measurements of our T-dwarf candidates in the AKARI (Yamauchi et al. 2011), WISE (Wright et al. 2010) and Spitzer databases. The AKARI and WISE all-sky surveys turn out to be too shallow for the detection of our T-dwarf candidates. However, three of them (ID 1, ID 2 and ID 3) have been detected in the deeper Spitzer $c2d$ Survey, which mapped Serpens together with other five nearby molecular clouds, using both IRAC and MIPS, the two imaging cameras on Spitzer (Evans et al. 2009). ID 4, the faintest of our candidates, was not detected by the $Spitzer$ $c2d$ Survey. The IRAC and MIPS 24 $\mu$m fluxes for ID 1, ID 2 and ID 3 are reported in Table 5. We also computed for these three candidates the SED slope between the $K$-band ($2.2$ $\mu$m) and the MIPS band at 24 $\mu$m ($\alpha_{[K,24 \mu m]}$, Table 5), which is traditionally used to assess the IR class of YSOs (Lada & Wilking 1984). The $\alpha_{[K,24 \mu m]}$ we obtain are upper limits to the actual SED slopes, because only flux upper limits are available at 24 $\mu$m for our objects.

In Fig. 6 (left panel) we compare the position of our candidates in the $K_S$ – [3.6] vs. [3.6]–[4.5] CC diagram with the locus expected for field dwarfs (Patten et al. 2006), the sequence defined by YSOs belonging to Serpens (Harvey et al. 2007; Winston et al. 2007) and the position of S Ori 70 and CFHT$_\text{J0344+3206}$.

In Fig. 6 (right panel) we use the $i - J$ vs. $J$ – [3.6] CC diagram to compare the colors of our candidates with the locus of YSOs in Serpens, the position of S Ori 70 and the colors expected for background QSOs, which might contaminate our sample. As demonstrated by Bouy et al. (2009), very low mass YSOs (with or without mid-IR excess associated to the presence
of a circumstellar disk) and QSOs occupy two very distinct areas of this diagram, thus it can be used to effectively separated the two populations.

Finally, in Fig. 7 we present the SEDs of our four candidates from the optical up to 24 μm. The line-filled area in each SED plot represents the flux variation depending on the adopted reddening correction (see Sect. 4 and Table 4). The spectrum overlapped to each SED is the COND model spectrum by Allard et al. (2001) and Baraffe et al. (2003) with the same effective temperature as the object, normalized to the J-band flux; this model represents the pure stellar photospheric emission expected for an object of the given $T_{\text{eff}}$.

The Spitzer colors of ID 1 and ID 2 (Fig. 6) are in general agreement with those of class III objects with thin or no disks. This is also in agreement with the shape of their SEDs, which might present a small IR excess emission only at 24 μm (Fig. 7). For both objects we find $\alpha_{(K\&24 \, \mu m)} \lesssim -1$, which is typical of class III objects with no prominent IR excess (Lada & Wilking 1984; Greene et al. 1994). Thus, the overall Spitzer colors/SED for these two objects indicate that they do not possess a clear IR excess emission typical of very young objects. Their position in the $i - J$ vs. $J - [3.6]$ diagram indicates that their colors, when corrected for the estimated interstellar extinction (Table 4), approach the locus expected for QSOs. Since they are too bright to be high-redshift QSOs, the most likely possibility is that they are heavily reddened low redshift QSOs. Indeed, we estimated that the Hα broad emission line of QSOs could contaminate the magnitude in the methane filters at redshift $z \sim 1.4$ (Richards et al. 2003).

The SED of ID 3 (Fig. 7) might present IR excess starting from 8 μm with a slope ($\alpha_{(K\&24 \, \mu m)} = 0.27 \pm 0.04$) typical of a class II YSO with a thick disk. However, only flux upper limits are available for $J \geq 8.5 \mu m$ and, hence, this $\alpha_{(K\&24 \, \mu m)}$ value is not robust. The interpretation of the $K_S - [3.6]$ vs. $[3.6] - [4.5]$ CC diagram (Fig. 6) is very uncertain because of the big error bars. However, the position of ID 3 appears to be consistent with the locus of field T-dwarfs. In particular, its $[3.6] - [4.5]$ color is bluer than expected for young mid-T dwarfs such as S Ori 70 and CFHT_J0344+3206. However, assuming that a thick disk surrounds this object, its $[3.6] - [4.5]$ color, peculiar for a young objects, might still be explained in term of different disk inclination with respect to S Ori 70 and CFHT_J0344+3206. Indeed, as shown in the top panels of Fig. 7 by Robitaille et al. (2006), disk inclination significantly alter the SED shape at mid-IR wavelengths (3–10 μm) for very low-mass objects ($\lesssim 0.2 \, M_\odot$). Finally, its position in the $i - J$ vs. $J - [3.6]$ diagram is clearly consistent with the YSO locus and, in particular, it is very close to the location of S Ori 70. More robust imaging data at mid-IR

### Table 5. Spitzer fluxes and SED slopes ($\alpha_{(K\&24 \, \mu m)}$) for the three T-dwarf candidates in this study detected by the Spitzer c2d survey.

| ID   | c2d Name                  | $\alpha_{(K\&24 \, \mu m)}$ | IRAC 3.6 μm (mJy) | IRAC 4.5 μm (mJy) | IRAC 5.8 μm (mJy) | IRAC 8 μm (mJy) | MIPS 24 μm (mJy) |

Fig. 5. $J$ vs. $J - K_S$ (left panel) and $J - H$ vs. $H - K_S$ diagrams (right panel) for the point-like objects detected in Serpens Core (small grey dots). The circles with error bars are the T-dwarf candidates in this study; their ID number is indicated and the arrows indicate their position after correction for interstellar reddening. The Serpens Core class II (black dots) and class III (asterisks) YSO population, the S Ori 70 mid-T dwarf (sky-blue diamond) and the CFHT_J0344+3206 mid-T dwarf candidate (green diamond) are plotted for comparison. The squares and triangles show the location of confirmed field L and T dwarfs (Chiu et al. 2006; Golimowski et al. 2004; Knapp et al. 2004), respectively, shifted to the distance of Serpens. Lines show the 5 Gyr and 3 My COND isochrones (dashed lines) and the 5 Gyr and 3 My DUSTY isochrones (continuous line).
Fig. 6. Left panel: $K_s - [3.6]$ vs. $[3.6] - [4.5]$ color–color diagram. The circles with error bars are our the T-dwarf candidates; their ID number (see Tables 3, 4) is indicated and the arrows indicate their position after correction for interstellar reddening. The Serpens Core class II (black dots) and class III (asterisks) YSO population, the S Ori 70 mid-T dwarf (sky-blue diamond), the CFHT_J0344+3206 mid-T dwarf candidate (green diamond) and the field dwarf sequence from Patten et al. (2006) (line-filled area) are plotted for comparison. Right panel: $i - J$ vs. $J - [3.6]$ color–color diagram. Symbols are as in the left panel. The dot-dashed ellipse marks the area occupied by QSOs in the SWIRE catalog (Hatziminaoglou et al. 2008).

Fig. 7. Spectral energy distributions of the T-dwarf candidates in this study. Flux errors are smaller than the symbol size and flux upper limits are marked with an arrow. The line-filled area represents the flux variation depending on the adopted reddening correction. The overplotted spectrum is the COND model by Allard et al. (2001) and Baraffe et al. (2003) with the same $T_{\text{eff}}$ as estimated for each object (indicated in the label and in Table 4) normalized to the $J$-band flux.
wavelengths and/or follow-up spectroscopy is needed to draw a firm conclusion about this object.

ID 4 is not detected in any of the Spitzer pass-bands and, hence, we can not assess the presence of a circumstellar disk around this object. For the sake of completeness, the optical/near-IR SED of ID 4 is shown in Fig. 7. The observed $i-J$ color of ID 4 (i.e., 2.43) is bluer than expected for early/mid T-dwarfs (see, e.g., Table 3 by Hawley et al. 2002), while its observed and dereddened $r-i$ color (1.43 and 0.82, respectively, adopting the Serpens extinction map ($A_{\text{V}}^\text{mid}$ in Table 4) are consistent with the $r-i$ colors expected for early/mid T-dwarfs (see, e.g., Table 3 by Hawley et al. 2002), in agreement with its near-IR colors (Fig. 5). Thus, our conclusions about this object remain as in Sect. 5.1: ID 4 may be a cluster member, although our data are not sufficient to conclusively prove this and spectroscopic follow-up is required.

6. Summary and conclusions

We presented a deep methane imaging survey for planetary-mass T-dwarfs in the Serpens Core cluster. Our survey covers a field of view of 21.5′ × 21.5′ and about 127 000 sources were detected in both the CH$_4$on and CH$_3$off filters.

We identified four potential T-dwarfs from their 1.6 μm methane absorption band and used complementary $riJHK_s$ broad-band imaging and mid-IR flux measurements from the Spitzer c2d Survey to investigate their stellar and disk properties.

Two of our candidates (ID 1 and ID 2) suffer from significant interstellar extinction and have near-IR colors similar to mid-T dwarfs. However, they are too bright to be planetary-mass members of Serpens and do not present the typical IR excess emission expected for young objects surrounded by a disk. Our analysis indicates that their dereddened near-IR colors approach the values expected for QSOs. In particular, since they are too bright to be high-redshift QSOs, they could be heavily redshifted low redshift QSOs.

Our candidate ID 3 does not present a significant interstellar extinction and its near-IR colors are more consistent with it being a field mid-T dwarf. It is brighter than field objects and, hence, it may be a foreground T-dwarf. It is detected by the Spitzer c2d survey but only flux upper limits are available for $I ≥ 5.8$ μm and, hence, we can not assess the presence of a possible disk around this object. However, it is worth to keep this possibility open, because the position on the $J$ vs. $J-K_s$ and $i-J$ vs. $J-[3.6]$ diagrams and the estimated spectral type of ID 3 are very similar to those of other young T-dwarf candidates, i.e. S Ori 70 and CFHT_J0344+3206 in the direction of IC 348.

Finally, ID 4 is significantly extincted, which exclude the possibility of it being a foreground object, and has dereddened optical and near-IR colors mainly consistent with those of early/mid T-dwarfs. It is brighter than field objects and, hence, it might be very young, as YSOs have larger radii and are brighter than older field objects of the same spectral class. Thus, ID 4 is a promising young T-dwarf candidate in our sample.

Considering the magnitudes of our candidates ID 3 and 4 (Table 3) and their $T_{\text{eff}}$ (Table 4) based on the dereddened CH$_4$on–CH$_3$off colors, we estimated their masses assuming that they belong to the Serpens Core cluster (i.e., age ~ 3 Myr and distance in the range 260–415 pc) and using both the COND and DUSTY evolutionary models by Chabrier et al. (2000). The estimated mass is in the range 2–4 Jupiter masses for both ID 3 and 4. Therefore, if they truly belong to the Serpens Core cluster, they would be amongst the youngest, lowest mass objects detected in a star-forming region so far.

Follow-up spectroscopy is required to confirm the spectral type and reddening of our four T-dwarf candidates and, hence, draw firm conclusions about their nature. Additional deep imaging at mid-IR wavelengths is needed to clarify the presence of a possible disk around ID 3.
