Abstract

We study in optimal control the important relation between invariance of the problem under a family of transformations, and the existence of preserved quantities along the Pontryagin extremals. Several extensions of Noether theorem are provided, in the direction which enlarges the scope of its application. We formulate a more general version of Noether’s theorem for optimal control problems, which incorporates the possibility to consider a family of transformations depending on several parameters and, what is more important, to deal with quasi-invariant and not necessarily invariant optimal control problems. We trust that this latter extension provides new possibilities and we illustrate it with several examples, not covered by the previous known optimal control versions of Noether’s theorem.

Mathematics Subject Classification 2000. 49K15

Keywords. optimal control, Pontryagin maximum principle, Noether theorem, conservation laws, invariance up to first-order terms in the parameters.

1 Introduction

The study of invariant variational problems

\[ J [x(\cdot)] = \int_a^b L (t, x(t), \dot{x}(t)) \, dt \rightarrow \min \]

in the calculus of variations was initiated in 1918 by Emmy Noether who, influenced by the works of Klein and Lie on the transformation properties of differential equations, published in her gorgeous paper [13, 14] a fundamental, and now classical result, known as Noether’s theorem. The universal principle described by Noether’s theorem (see e.g. [5] pp. 262–266], [14 §4.3., or [6 §20]), asserts that invariance of the integral functionals of the calculus of variations with respect to a family of transformations result in existence of a certain conservation
law or equivalently a first integral of the corresponding Euler-Lagrange differential equations. This means that the invariance hypothesis leads to quantities, computed in terms of the Lagrangian and the family of transformations, which are constant along the extremals. This result is of great importance in physics, engineering, systems and control and their applications (see [18, 9, 12, 1]). One important application of the Noether theorem is, for example, to the n-body problem. For a discussion of this problem, and interpretation of the respective first integrals from invariance under Galilean transformations and application of Noether’s theorem, we refer the reader to [11] and [7, pp. 190–192] or [9] Ch. 2.

In the optimal control setting, the relation between invariance of a problem and the existence of expressions which are constant along any of its extremals, has been obtained in the publications by van der Schaft [25] and Sussmann [17], following the classical Noether’s approach based on the transversality conditions1 (cf. [3, 4]). Using the original paper of Emmy Noether [13, 14] and the more simpler and direct approach of Andrzej Trautman [24], Hanno Rund [16] (see also [10]) and John David Logan [9] for insight and motivation, extensions to the previous known optimal control versions of Noether’s theorem were obtained by the present author in [20, 22, 23]. Here we attempt to enlarge the range of application of the theorems, extending the very concept of invariance (Definition 3.1) by allowing several parameters and equalities up to first-order terms in the parameters (quasi-invariance). This extension allows one to formulate a Noether type theorem for optimal control problems (Theorem 5.1) in a much broader way, enlarging the scope of its application. Examples not covered by the previous optimal control versions of Noether’s theorem are provided in detail.

2 The Maximum Principle

Consider the following optimal control problem, denoted in the sequel by (P) : to minimize the integral functional

\[ J [x(\cdot), u(\cdot)] = \int_a^b L (t, x(t), u(t)) \, dt \]

over the class \( W^{1,1} \) of absolutely continuous state trajectories \( x(\cdot) = (x_1(\cdot), \ldots, x_n(\cdot)) \) mapping \([a, b]\) to \( \mathbb{R}^n \), and the class \( L^\infty \) of measurable and essentially bounded controls \( u(\cdot) = (u_1(\cdot), \ldots, u_m(\cdot)) \) mapping \([a, b]\) to a given set \( \Omega \subseteq \mathbb{R}^m \), subject to the dynamic control system

\[ \dot{x}(t) = \varphi (t, x(t), u(t)) \quad \text{for a.a. } t \in [a, b], \]

where \( L \) and \( \varphi \) are assumed to be \( C^1 \).

The next theorem gives a summary of the celebrated Pontryagin maximum principle [15], which is the first-order necessary optimality condition of optimal control theory.

**Theorem 2.1 (Pontryagin maximum principle).** Let \( (x(\cdot), u(\cdot)) \) be a minimizer of the optimal control problem (P). Then, there exists a nonzero pair

---
1In the calculus of variations, transversality conditions are expressed by the so called general variation of the functional (see e.g. [3] §13 or [7] p. 185).
\( \psi_0, \psi(\cdot) \), where \( \psi_0 \leq 0 \) is a constant and \( \psi(\cdot) \) a \( n \)-vector absolutely continuous function with domain \([a, b]\), such that the following hold for almost all \( t \) on the interval \([a, b]\):

(i) the Hamiltonian system

\[
\begin{align*}
\dot{x}(t) &= \frac{\partial H(t, x(t), u(t), \psi_0, \psi(t))}{\partial \psi}, \\
\dot{\psi}(t) &= -\frac{\partial H(t, x(t), u(t), \psi_0, \psi(t))}{\partial x};
\end{align*}
\]

(ii) the maximality condition

\[
H(t, x(t), u(t), \psi_0, \psi(t)) = \max_{v \in \Omega} H(t, x(t), v, \psi_0, \psi(t));
\]

with the Hamiltonian \( H(t, x, u, \psi_0, \psi) = \psi_0 L(t, x, u) + \psi \cdot \phi(t, x, u) \).

**Definition 2.1.** A quadruple \((x(\cdot), u(\cdot), \psi_0, \psi(\cdot))\) satisfying the Hamiltonian system and the maximality condition is called a (Pontryagin) extremal.

**Remark 2.1.** Depending on the specific boundary conditions under consideration in problem \((P)\), transversality conditions may also appear in the Pontryagin maximum principle. As far as the results obtained are valid for arbitrary boundary conditions and the methods which we will employ do not require the use of such transversality conditions, they are not included in Theorem 2.1.

## 3 The Quasi-Invariance Definition

The following notion generalizes the invariance definitions used in previous versions of Noether’s theorem up to first-order terms in the \( r \) parameters \( s_1, \ldots, s_r \) (cf. e.g. [22, Definition 5]).

**Definition 3.1.** If there exists a \( C^1 \) smooth \( r \)-parameter family of transformations

\[
h^s : [a, b] \times \mathbb{R}^n \times \Omega \to \mathbb{R} \times \mathbb{R}^n \times \mathbb{R}^m,
\]

\[
h^s(t, x, u) = (T(t, x, u, s), X(t, x, u, s), U(t, x, u)) ,
\]

\[
s = (s_1, \ldots, s_r), \|s\| = \sqrt{\sum_{k=1}^{r} (s_k)^2 < \varepsilon},
\]

which for \( s = 0 \) reduce to the identity map, \( h^0(t, x, u) = (t, x, u) \) for all \((t, x, u) \in [a, b] \times \mathbb{R}^n \times \Omega\), and satisfying

\[
L(t, x(t), u(t)) + \frac{d}{dt} F(t, x(t), u(t), s) + o(s)
\]

\[
= L \circ h^s(t, x(t), u(t)) \frac{d}{dt} T(t, x(t), u(t), s),
\]

\[
\frac{d}{dt} X(t, x(t), u(t), s) + o(s) = \varphi \circ h^s(t, x(t), u(t)) \frac{d}{dt} T(t, x(t), u(t), s),
\]

(3)
for some function $F$ of class $C^1$ and where $o(s)$ denote terms which go to zero faster than $\|s\|$, i.e.,

$$\lim_{\|s\| \to 0} \frac{o(s)}{\|s\|} = 0,$$

then problem $(P)$ is said to be quasi-invariant under $h^s$.

**Remark 3.1.** The types of invariance transformations that we consider are transformations of the $(t, x_1, \ldots, x_n, u_1, \ldots, u_m)$-space which depend upon $r$ small real independent parameters $s_1, \ldots, s_r$. In Noether’s original paper [13, 14], as well as in more recent treatments of invariant problems of optimal control (e.g. [3]), it is assumed that the transformations form a group. In the present work, however, we follow the approaches in [23] and [22] and we make less stringent assumptions on the transformations – the group concept is not required for the investigation of quasi-invariant optimal control problems.

The following example shows an optimal control problem quasi-invariant under a one-parameter family of transformations, in the sense of Definition 3.1, but not invariant under all previous invariance definitions [25, 17, 3, 4, 20, 22, 23] used in connection with the Noether theorem. This is due to the fact that the integral is not invariant, but rather invariant up to an exact differential and to first-order terms in the parameter $s$; while the third component $\varphi_3$ of the phase velocity vector is also invariant only up to first-order terms in the parameter (quasi-invariant).

**Example 3.1** ($n = 3$, $m = 2$). We consider problem $(P)$ with $L = u_1^2 + u_2^2$ and $\varphi = (u_1, u_2, \frac{u_2^2}{2})^T$:

$$\int_a^b (u_1(t))^2 + (u_2(t))^2 \, dt \rightarrow \min,$$

$$\begin{align*}
  \dot{x}_1(t) &= u_1(t), \\
  \dot{x}_2(t) &= u_2(t), \\
  \dot{x}_3(t) &= \frac{u_2(t) (x_2(t))^2}{2}.
\end{align*}$$

Direct calculations show that the problem is invariant under $h^s(t, x_1, x_2, x_3, u_1, u_2) = (t, x_1 + st, x_2 + st, x_3 + \frac{1}{2} x_2^2 st, u_1 + s, u_2 + s)$:

$$h^0(t, x_1, x_2, x_3, u_1, u_2) = (t, x_1, x_2, x_3, u_1, u_2),$$

$$L \circ h^s \frac{d}{dt}(t) = (u_1 + s)^2 + (u_2 + s)^2 = (u_1^2 + u_2^2) + 2s (u_1 + u_2) + 2s^2,$$
and equation (2) is satisfied with

\[ F(x_1, x_2, s) = 2s(x_1 + x_2) \text{ and } o(s) = 2s^2; \]

\[ \varphi_1 \circ h^s \frac{d}{dt}(t) = u_1 + s = \frac{d}{dt}(x_1 + st), \]

\[ \varphi_2 \circ h^s \frac{d}{dt}(t) = u_2 + s = \frac{d}{dt}(x_2 + st), \]

\[ \varphi_3 \circ h^s \frac{d}{dt}(t) = \frac{(u_2 + s)(x_2 + s)^2}{2} = \frac{u_2x_2^2}{2} + \frac{1}{2}s(x_2^2 + 2x_2u_2t) + \frac{(u_2t^2 + 2x_2) s^2 + t^2s^3}{2}, \]

\[ \left( o(s) = \frac{(u_2t^2 + 2x_2) s^2 + t^2s^3}{2} \right) \] and (3) is also satisfied.

### 4 The Fundamental Invariance Theorem

The next fundamental theorem is useful in many ways: to derive conservation laws for a given quasi-invariant problem \((P)\) (we will see in Section 5 how Theorem 4.1 provide a simple and direct access to a Noether theorem – Theorem 5.1) and to give conditions which allow us to determine a family of transformations under which a given optimal control problem is quasi-invariant (see Examples 4.1 and 4.2, and the ones in Section 6). If only the transformations are known, equations (5) and (6) represent first-order partial differential equations in the unknown functions \(L\) and \(\varphi\), and the fundamental theorem can be used to characterize a set of optimal control problems which possess given invariance properties (cf. [21 §4.2]).

**Theorem 4.1.** Necessary conditions for problem \((P)\) to be quasi-invariant under the \(r\)-parameter family of transformations \((1)\) are \((k = 1, \ldots, r)\):

\[ \frac{d}{dt} \frac{\partial F}{\partial s_k} \bigg|_{s=0} = \frac{\partial L}{\partial t} \frac{\partial T}{\partial s_k} \bigg|_{s=0} + \frac{\partial L}{\partial x} \frac{\partial X}{\partial s_k} \bigg|_{s=0} + \frac{\partial L}{\partial u} \frac{\partial U}{\partial s_k} \bigg|_{s=0} + L \frac{d}{dt} \frac{\partial T}{\partial s_k} \bigg|_{s=0}, \]

\[ \frac{d}{dt} \frac{\partial X}{\partial s_k} \bigg|_{s=0} = \frac{\partial \varphi}{\partial t} \frac{\partial T}{\partial s_k} \bigg|_{s=0} + \frac{\partial \varphi}{\partial x} \frac{\partial X}{\partial s_k} \bigg|_{s=0} + \frac{\partial \varphi}{\partial u} \frac{\partial U}{\partial s_k} \bigg|_{s=0} + \varphi \frac{d}{dt} \frac{\partial T}{\partial s_k} \bigg|_{s=0}. \]

**Proof.** The proof follows as a simple exercise from the definition of quasi-invariance: using \(h^0(t, x, u) = (t, x, u)\), it suffices to differentiate (2) and (3) with respect to \(s_k\) and then set \(s = 0\).

**Remark 4.1.** We are assuming in Theorems 4.1 and 5.1 the possibility to reverse the order of differentiation.

**Remark 4.2.** From (2) one has

\[ o(s) = L \circ h^s \frac{d}{dt} T(t, x(t), u(t), s) - L \frac{d}{dt} F(t, x(t), u(t), s), \]
while from (3) one obtains
\[ o(s) = \varphi \circ h^s \frac{d}{dt} \left( T(t, x(t), u(t), s) - \frac{d}{dt} X(t, x(t), u(t), s) \right). \]

From these equalities, explicit formulas for the derivatives of each \( o(s_1, \ldots, s_r) \) with respect to \( s_k \) \( (k = 1, \ldots, r) \) can be found. The derivatives vanish for \( s = (s_1, \ldots, s_r) = 0 \) due to (4).

The next two examples illustrate how Theorem 4.1 can be used to guess a family of transformations which maintain the problem invariant in the sense of Definition 5.1. Once again, the possibility of invariance up to first-order terms in the parameter (quasi-invariance) is crucial.

**Example 4.1.** \( (n = 4, m = 2) \) Let us consider the problem
\[
\int_a^b \left( (u_1(t))^2 + (u_2(t))^2 \right) dt \to \min,
\]
\[
\begin{align*}
x_1(t) &= x_3(t) \\
x_2(t) &= x_4(t) \\
x_3(t) &= -x_1(t) \left( (x_1(t))^2 + (x_2(t))^2 \right) + u_1(t) \\
x_4(t) &= -x_2(t) \left( (x_1(t))^2 + (x_2(t))^2 \right) + u_2(t),
\end{align*}
\]
and look for a one-parameter family of transformations without changing the time-variable \( (T = t) \) and with \( F \equiv 0 \), under which the problem is quasi-invariant. Theorem 4.1 asserts that the following conditions must hold:

\[
\begin{align*}
\left. \left( \frac{\partial U_1}{\partial s} \right) \right|_{s=0} &= -u_2 \left. \left( \frac{\partial U_2}{\partial s} \right) \right|_{s=0} \\
\left. \left( \frac{d}{dt} \frac{\partial X_1}{\partial s} \right) \right|_{s=0} &= \left. \left( \frac{\partial X_3}{\partial s} \right) \right|_{s=0} \\
\left. \left( \frac{d}{dt} \frac{\partial X_2}{\partial s} \right) \right|_{s=0} &= \left. \left( \frac{\partial X_4}{\partial s} \right) \right|_{s=0} \\
\left. \left( \frac{d}{dt} \frac{\partial X_3}{\partial s} \right) \right|_{s=0} &= -\left. \left( 3x_1^2 + x_2^2 \right) \frac{\partial X_1}{\partial s} \right|_{s=0} - 2x_1x_2 \left. \left( \frac{\partial X_2}{\partial s} \right) \right|_{s=0} + \left. \left( \frac{\partial U_1}{\partial s} \right) \right|_{s=0} \\
\left. \left( \frac{d}{dt} \frac{\partial X_4}{\partial s} \right) \right|_{s=0} &= -2x_1x_2 \left. \left( \frac{\partial X_1}{\partial s} \right) \right|_{s=0} - \left. \left( x_1^2 + 3x_2^2 \right) \frac{\partial X_2}{\partial s} \right|_{s=0} + \left. \left( \frac{\partial U_2}{\partial s} \right) \right|_{s=0}.
\end{align*}
\]

One easily obtains that (7) is satisfied for
\[
\begin{align*}
\left. \frac{\partial U_1}{\partial s} \right|_{s=0} &= -u_2, & \left. \frac{\partial U_2}{\partial s} \right|_{s=0} &= u_1, \\
\left. \frac{\partial X_1}{\partial s} \right|_{s=0} &= -x_2, & \left. \frac{\partial X_2}{\partial s} \right|_{s=0} &= x_1, & \left. \frac{\partial X_3}{\partial s} \right|_{s=0} &= -x_4, & \left. \frac{\partial X_4}{\partial s} \right|_{s=0} &= x_3.
\end{align*}
\]
Choosing \( U_1 = u_1 - u_2 s, \ U_2 = u_2 + u_1 s, \ X_1 = x_1 - x_2 s, \ X_2 = x_2 + x_1 s, \ X_3 = x_3 - x_4 s, \ X_4 = x_4 + x_3 s, \) one can verify that conditions 2 and 3 are
indeed true:

\[ L \circ h^s \frac{d}{dt} T = (u_1 - u_2 s)^2 + (u_2 + u_1 s)^2 = (u_1^2 + u_2^2) + (u_1^2 + u_2^2) s^2 = L + o(s), \]
\[ \varphi_1 \circ h^s \frac{d}{dt} T = x_3 - x_4 s = \frac{d}{dt} (x_1 - x_2 s) = \frac{d}{dt} X_1, \]
\[ \varphi_2 \circ h^s \frac{d}{dt} T = x_4 + x_3 s = \frac{d}{dt} (x_2 + x_1 s) = \frac{d}{dt} X_2, \]
\[ \varphi_3 \circ h^s \frac{d}{dt} T = - (x_1 - x_2 s) ((x_1 - x_2 s)^2 + (x_2 + x_1 s)^2) + u_1 - u_2 s \]
\[ = [-x_1(x_1^2 + x_2^2) + u_1 + x_2(x_1^2 + x_2^2) s - u_2 s] + [(x_2 s - x_1)(x_1^2 + x_2^2) s^2] \]
\[ = \frac{d}{dt} X_3 + o(s), \]
\[ \varphi_4 \circ h^s \frac{d}{dt} T = - (x_2 + x_1 s) ((x_1 - x_2 s)^2 + (x_2 + x_1 s)^2) + u_2 + u_1 s \]
\[ = [-x_2(x_1^2 + x_2^2) + u_2 - x_1(x_1^2 + x_2^2) s + u_1 s] + [-(x_2 - x_1 s)(x_1^2 + x_2^2) s^2] \]
\[ = \frac{d}{dt} X_4 + o(s). \]

**Example 4.2.** \((n = 4, m = 2)\) Consider the problem:

\[
\begin{aligned}
\dot{x}_1 &= u_1(1 + x_2) \\
\dot{x}_2 &= u_1 x_3 \\
\dot{x}_3 &= u_2 \\
\dot{x}_4 &= u_1 x_3^2
\end{aligned}
\]

with \(L = u_1^2 + u_2^2\). From Theorem 4.1 we get the following necessary conditions for the one-parameter transformation \(h^s = (T, X_1, X_2, X_3, X_4, U_1, U_2)\) to leave the problem quasi-invariant:

\[
\begin{aligned}
\frac{d}{dt} \left[ \frac{\partial F}{\partial s} \right]_{s=0} &= 2u_1 \left. \frac{\partial U_1}{\partial s} \right|_{s=0} + 2u_2 \left. \frac{\partial U_2}{\partial s} \right|_{s=0} + (u_1^2 + u_2^2) \left. \frac{d}{dt} \frac{\partial T}{\partial s} \right|_{s=0} \\
\frac{d}{dt} \left[ \frac{\partial X_1}{\partial s} \right]_{s=0} &= u_1 \left. \frac{\partial X_2}{\partial s} \right|_{s=0} + (1 + x_2) \left. \frac{\partial U_3}{\partial s} \right|_{s=0} + u_1 (1 + x_2) \left. \frac{d}{dt} \frac{\partial T}{\partial s} \right|_{s=0} \\
\frac{d}{dt} \left[ \frac{\partial X_2}{\partial s} \right]_{s=0} &= u_1 \left. \frac{\partial X_3}{\partial s} \right|_{s=0} + x_3 \left. \frac{\partial U_1}{\partial s} \right|_{s=0} + u_1 x_3 \left. \frac{d}{dt} \frac{\partial T}{\partial s} \right|_{s=0} \\
\frac{d}{dt} \left[ \frac{\partial X_3}{\partial s} \right]_{s=0} &= \left. \frac{U_2}{\partial s} \right|_{s=0} + u_2 \left. \frac{d}{dt} \frac{\partial T}{\partial s} \right|_{s=0} \\
\frac{d}{dt} \left[ \frac{\partial X_4}{\partial s} \right]_{s=0} &= 2u_1 x_3 \left. \frac{\partial X_3}{\partial s} \right|_{s=0} + x_3^2 \left. \frac{\partial U_1}{\partial s} \right|_{s=0} + u_1 x_3^2 \left. \frac{d}{dt} \frac{\partial T}{\partial s} \right|_{s=0}.
\end{aligned}
\]

The conditions are satisfied with \(F \equiv 0\) and

\[
\left. \frac{\partial U_1}{\partial s} \right|_{s=0} = -u_1, \quad \left. \frac{\partial U_2}{\partial s} \right|_{s=0} = -u_2, \quad \left. \frac{d}{dt} \frac{\partial T}{\partial s} \right|_{s=0} = 2, \\
\left. \frac{\partial X_1}{\partial s} \right|_{s=0} = 3x_1, \quad \left. \frac{\partial X_2}{\partial s} \right|_{s=0} = 2(1 + x_2), \quad \left. \frac{\partial X_3}{\partial s} \right|_{s=0} = x_3, \quad \left. \frac{\partial X_4}{\partial s} \right|_{s=0} = 3x_4.
\]

With the transformations \(U_1 = u_1(1 - s), U_2 = u_2(1 - s), T = t(1 + 2s), X_1 = x_1(1 + 3s), X_2 = x_2 + 2s(1 + x_2), X_3 = x_3(1 + s), X_4 = x_4(1 + 3s), \) the
problem is quasi-invariant:

\[
L \circ h = \frac{d}{dt} T = (u_1^2 + u_2^2) + (u_1^2 + u_2^2) (2s - 3) s^2,
\]

\[
\varphi_1 \circ h = \frac{d}{dt} T = \frac{d}{dt} (x_1(1 + 3s)) - 4u_1(1 + x_2)s^3,
\]

\[
\varphi_2 \circ h = \frac{d}{dt} T = \frac{d}{dt} (x_2 + 2s(1 + x_2)) - u_1x_3(1 + 2s)s^2,
\]

\[
\varphi_3 \circ h = \frac{d}{dt} T = \frac{d}{dt} (x_3(1 + s)) - 2u_2s^2,
\]

\[
\varphi_4 \circ h = \frac{d}{dt} T = \frac{d}{dt} (x_4(1 + 3s)) + u_1x_3^2 (1 - 3s - 2s^2) s^2.
\]

We will now see how to derive conservation laws from the knowledge of such \( T, F \) and \( X_i \)'s (\( i = 1, \ldots, n \)).

5 The Noether Theorem and Conservation Laws

Now we obtain, as a corollary of Theorem 4.1, a far more general Noether theorem for optimal control problems, which permits to construct conserved quantities along the Pontryagin extremals of the problem. Theorem 5.1 gives \( r \) conservation laws when problem \((P)\) is quasi-invariant under a family of transformations containing \( r \) parameters.

**Theorem 5.1.** If problem \( (P) \) is quasi-invariant under an \( r \)-parameter family of transformations \( \{h^s\} \) then, for any quadruple \( (x(\cdot), u(\cdot), \psi_0, \psi(\cdot)) \) satisfying the Pontryagin maximum principle for \((P)\), the \( r \) expressions hold true (\( k = 1, \ldots, r \)):

\[
\psi_0 \frac{\partial F(t, x(t), u(t), s)}{\partial s_k} \bigg|_{s=0} + \psi(t) \cdot \frac{\partial X(t, x(t), u(t), s)}{\partial s_k} \bigg|_{s=0} - H(t, x(t), u(t), \psi_0, \psi(t)) \frac{\partial T(t, x(t), u(t), s)}{\partial s_k} \bigg|_{s=0} \equiv \text{constant},
\]

\( t \in [a, b] \), with \( H \) the Hamiltonian associated to the problem \((P)\): \( H(t, x, u, \psi_0, \psi) = \psi_0L(t, x, u) + \psi \cdot \varphi(t, x, u) \).

**Remark 5.1.** Following the usual terminology (cf. e.g. [2, p. 554], [8]), we call a function \( C(t, x, u, \psi_0, \psi) \) which is constant along every Pontryagin extremal \((x(\cdot), u(\cdot), \psi_0, \psi(\cdot))\) of \((P)\),

\[
C(t, x(t), u(t), \psi_0, \psi(t)) = k, \tag{8}
\]

for some constant \( k \), a constant of the motion or a first integral. The equation \( \text{(8)} \) is called the conservation law corresponding to the first integral \( C(\cdot, \cdot, \cdot, \cdot, \cdot) \).

**Remark 5.2.** As far as everything under consideration, including the Pontryagin maximum principle, is of a local character, the fact that we restrict ourselves to state variables in Euclidean spaces \( \mathbb{R}^n \) does not lead to any loss of generality. In particular, Theorem 5.1 is easily formulated on Manifolds.
Example 5.1. For the problem considered in Example 4.1 we conclude from Theorem 5.1 that $2\psi_0 (x_1(t) + x_2(t)) + \psi_1(t) t + \psi_2(t) t + \frac{1}{4} \psi_3(t) (x_2(t))^2$ is constant along the Pontryagin extremals.

Example 5.2. For the problem in Example 4.1 the following first integral follows from Theorem 5.1: $-\psi_1(t) x_2(t) + \psi_2(t) x_1(t) - \psi_3(t) x_4(t) + \psi_4(t) x_3(t)$.

Example 5.3. From Example 5.2 and Theorem 5.1 the following constant of the motion holds:

$$3\psi_1(t) x_1(t) + 2\psi_2(t) (1 + x_2(t)) + \psi_3(t) x_3(t) + 3\psi_4(t) x_4(t) - 2t H,$$

with $H = \psi_0 ((u_1(t))^2 + (u_2(t))^2) + \psi_1(t) u_1(t) (1 + x_2(t)) + \psi_2(t) u_1(t) x_3(t) + \psi_3(t) u_2(t) + \psi_4(t) u_1(t) (x_3(t))^2$.

**Remark 5.3.** All the conservation laws obtained in the previous examples are not obvious and not expected *a priori*. However, once obtained, they can easily be checked, by differentiation, using the corresponding adjoint system $\dot{\psi} = -\frac{\partial H}{\partial x}$ and the extremality condition $\frac{\partial H}{\partial u} = 0$. Let us illustrate this issue for Example 5.2. From the adjoint system we get that $\dot{\psi}_1$ and $\dot{\psi}_4$ are constants, while $\dot{\psi}_2(t)$ and $\dot{\psi}_3(t)$ satisfy $\dot{\psi}_2(t) = -\psi_1 u_1(t)$, $\dot{\psi}_3(t) = -\psi_2 u_1(t) - 2\psi_4 u_1(t) x_3(t)$. Having in mind that the problem is autonomous, and therefore the Hamiltonian $H$ is constant along the extremals (cf. (21)), differentiation of (9) allows us to write that

$$3\psi_1 u_1(t) (1 + x_2(t)) - 2\psi_1 u_1(t) (1 + x_2(t)) + 2\psi_2(t) u_1(t) x_3(t) - \psi_2(t) u_1(t) x_3(t) - 2\psi_4 u_1(t) (x_3(t))^2 + \psi_3(t) u_2(t) + 3\psi_4 u_1(t) (x_3(t))^2 - 2H = 0,$$

that is,

$$\psi_1 (1 + x_2(t)) u_1(t) + \psi_2(t) x_3(t) u_1(t) + \psi_3(t) u_2(t) + \psi_4 x_3(t))^2 u_1(t) = 2H.$$

From the definition of the Hamiltonian, equality (10) is equivalent to $H = -\psi_0 \left((u_1(t))^2 + (u_2(t))^2\right)$, a relation that immediately follows from the extremality condition:

$$\left\{ \begin{array}{l} 2\psi_0 u_1(t) + \psi_1 (1 + x_2(t)) + 2\psi_2(t) x_3(t) + \psi_4 (x_3(t))^2 = 0 \\ 2\psi_0 u_2(t) + \psi_3(t) = 0 \end{array} \right.$$

$$\Rightarrow \left\{ \begin{array}{l} \psi_1 (1 + x_2(t)) u_1(t) + \psi_2(t) x_3(t) u_1(t) + \psi_4 (x_3(t))^2 u_1(t) = -2\psi_0 (u_1(t))^2 \\ \psi_3(t) u_2(t) = -2\psi_0 (u_2(t))^2 \end{array} \right.$$

**Proof. (Theorem 5.1)** Let $(x(\cdot), u(\cdot), \psi_0, \psi(\cdot))$ be a Pontryagin extremal of $(P)$. Multiplying (5) by $\psi_0$, (6) by $\psi(t)$, we can write:

$$\psi_0 \frac{d}{dt} \frac{\partial F}{\partial s_k} \bigg|_{s_0} + \psi(t) \cdot \frac{d}{dt} \frac{\partial X}{\partial s_k} \bigg|_{s_0} = \psi_0 \left( \frac{\partial L}{\partial t} \bigg|_{s_0} + \frac{\partial L}{\partial x} \bigg|_{s_0} + \frac{\partial \dot{L}}{\partial \dot{u}} \frac{\partial X}{\partial s_k} \bigg|_{s_0} + \frac{\partial \dot{L}}{\partial \dot{u}} \frac{\partial U}{\partial s_k} \bigg|_{s_0} + L \frac{d}{dt} \frac{\partial T}{\partial s_k} \bigg|_{s_0} \right)$$

$$+ \psi(t) \cdot \left( \frac{\partial \varphi}{\partial t} \bigg|_{s_0} + \frac{\partial \varphi}{\partial x} \frac{\partial X}{\partial s_k} \bigg|_{s_0} + \frac{\partial \varphi}{\partial \dot{u}} \frac{\partial U}{\partial s_k} \bigg|_{s_0} + \varphi \frac{d}{dt} \frac{\partial T}{\partial s_k} \bigg|_{s_0} \right).$$

(11)
According to the maximality condition of the Pontryagin maximum principle, the function 

\[ \psi_0 L(t, x(t), U(t, x(t), u(t)), s) + \psi(t) \cdot \varphi(t, x(t), U(t, x(t), u(t)), s) \]

attains an extremum for \( s = 0 \). Therefore for each \( k \in \{1, \ldots, r\} \)

\[ \psi_0 \frac{\partial L}{\partial u} \cdot \frac{\partial U}{\partial s_k} \bigg|_{s=0} + \psi(t) \cdot \frac{\partial \varphi}{\partial u} \cdot \frac{\partial U}{\partial s_k} \bigg|_{s=0} = 0 \]

and (11) simplifies to

\[
\psi_0 \left( \frac{\partial L}{\partial t} \frac{\partial T}{\partial s_k} \bigg|_{s=0} + \frac{\partial L}{\partial x} \frac{\partial X}{\partial s_k} \bigg|_{s=0} + L \frac{d}{dt} \frac{\partial T}{\partial s_k} \bigg|_{s=0} - \frac{d}{dt} \frac{\partial F}{\partial s_k} \bigg|_{s=0} \right) + \psi(t) \cdot \left( \frac{\partial \varphi}{\partial t} \frac{\partial T}{\partial s_k} \bigg|_{s=0} + \frac{\partial \varphi}{\partial x} \frac{\partial X}{\partial s_k} \bigg|_{s=0} + \varphi \frac{d}{dt} \frac{\partial T}{\partial s_k} \bigg|_{s=0} - \frac{d}{dt} \frac{\partial X}{\partial s_k} \bigg|_{s=0} \right) = 0.
\]

Using the adjoint system \( \dot{\psi} = -\frac{\partial H}{\partial x} \) and the equality \( \frac{dH}{dt} = \frac{\partial H}{\partial t} \) (cf. [21]), one easily concludes that the above equality is equivalent to

\[
\frac{d}{dt} \left( \psi_0 \frac{\partial F}{\partial s_k} \bigg|_{s=0} + \psi(t) \cdot \frac{\partial X}{\partial s_k} \bigg|_{s=0} - H \frac{\partial T}{\partial s_k} \bigg|_{s=0} \right) = 0.
\]

The proof is complete.

\[ \square \]

6 Illustrative Examples

The following proposition extends the study of the Martinet flat problem of sub-Riemannian geometry in [23, §4] (see Example 6.1 below) to the general homogeneous case.

**Proposition 6.1.** If there exist constants \( \alpha, \beta_1, \ldots, \beta_n, \gamma_1, \ldots, \gamma_m \in \mathbb{R} \), such that for all \( \lambda > 0 \)

\[
L(\lambda^\alpha t, \lambda^\beta_1 x_1, \ldots, \lambda^\beta_n x_n, \lambda^\gamma_1 u_1, \ldots, \lambda^\gamma_m u_m) = \lambda^{-\alpha} L(t, x_1, \ldots, x_n, u_1, \ldots, u_m),
\]

\[(12)\]

\[
\varphi_i(\lambda^\alpha t, \lambda^\beta_1 x_1, \ldots, \lambda^\beta_n x_n, \lambda^\gamma_1 u_1, \ldots, \lambda^\gamma_m u_m) = \lambda^{\beta_i - \alpha} \varphi_i(t, x_1, \ldots, x_n, u_1, \ldots, u_m),
\]

\[(13)\]

\( (i = 1, \ldots, n) \)

then

\[
\sum_{i=1}^n \beta_i \psi_i(t) x_i(t) - \alpha H(t, x(t), u(t), \psi_0, \psi(t)) t \equiv \text{constant}
\]

along any Pontryagin extremal \((x(\cdot), u(\cdot), \psi_0, \psi(t))\) of \((P)\).

**Proof.** Differentiating (12) and (13) with respect to \( \lambda \), and setting \( \lambda = 1 \), we
get
\[
\alpha L(t, x, u) + \alpha \frac{\partial L(t, x, u)}{\partial t} t + \sum_{j=1}^{n} \beta_j \frac{\partial L(t, x, u)}{\partial x_j} x_j + \sum_{k=1}^{m} \gamma_k \frac{\partial L}{\partial u_k} u_k = 0 ,
\]
\[
(\alpha - \beta_i) \varphi_1(t, x, u) + \alpha \frac{\partial \varphi_1(t, x, u)}{\partial t} t + \sum_{j=1}^{n} \beta_j \frac{\partial \varphi_1(t, x, u)}{\partial x_j} x_j + \sum_{k=1}^{m} \gamma_k \frac{\partial \varphi_1}{\partial u_k} u_k = 0 .
\]

From these equations, one concludes that conditions (5) and (6) of the fundamental invariance theorem are fulfilled if we choose \( F \equiv 0 \) and a one-parameter family of transformations satisfying the relations
\[
\frac{\partial T}{\partial s} \big|_{s=0} = \alpha t, \quad \frac{\partial X_i}{\partial s} \big|_{s=0} = \beta_i x_i, \quad \frac{\partial U_k}{\partial s} \big|_{s=0} = \gamma_k u_k .
\]
(14)

For that it suffices to choose \( T = e^{\alpha s t}, X_i = e^{\beta_i s} x_i (i = 1, \ldots, n), \) and \( U_k = e^{\gamma_k s} u_k (k = 1, \ldots, m) \). The problem is quasi-invariant under these transformations (Definition 3.1) and the conclusion follows from Theorem 5.1.

**Remark 6.1.** It is possible to prove the Proposition 6.1 with other choices of the parameter family of maps satisfying (14). For example, the same conclusion follows from Theorem 5.1 with \( T = (s+1)^{\alpha t}, X_i = (s+1)^{\beta_i} x_i, U_k = (s+1)^{\gamma_k} u_k, \) and \( F \equiv 0, \) or \( T = (1+\alpha s) t, X_i = (1+\beta_i s) x_i, \) and \( U_k = (1+\gamma_k s) u_k. \)

**Example 6.1 (n = 3, m = 2)**. In the Martinet flat problem of sub-Riemannian geometry, \( L = u_1^2 + u_2^2, \varphi_1 = u_1, \varphi_2 = u_2, \varphi_3 = \frac{u_1 u_2}{2} \). For \( \alpha = 2, \beta_1 = \beta_2 = 1, \beta_3 = 3, \gamma_1 = \gamma_2 = -1, \) one concludes from Proposition 6.1 that
\[
\psi_1(t) x_1(t) + \psi_2(t) x_2(t) + \psi_3(t) x_3(t) = 2 H t
\]
is constant in \( t \) along any Pontryagin extremal
\[
(x_1(\cdot), x_2(\cdot), x_3(\cdot), u_1(\cdot), u_2(\cdot), \psi_0, \psi_1(\cdot), \psi_2(\cdot), \psi_3(\cdot))
\]
of the problem, with \( H \) the Hamiltonian
\[
H(x_2, u_1, u_2, \psi_0, \psi_1, \psi_2, \psi_3) = \psi_0 (u_1^2 + u_2^2) + \psi_1 u_1 + \psi_2 u_2 + \psi_3 \frac{u_1 u_2}{2} .
\]
The first integral (15) was first discovered in [22].

Now we will consider optimal control problems subject to control-affine dynamics with drift. In all the cases our new version of Noether’s theorem is in order. The application of Theorem 5.1 with invariance up to first-order terms of the parameter \( s \) will be crucial in the examples, and therefore the first integrals we obtain cannot be deduced from the previous results in [25, 17, 3, 4, 20, 22, 23].

**Example 6.2 (n = 2, m = 1)**. Consider problem (P) with \( L = u^2, \varphi_1 = 1 + y^2 \) and \( \varphi_2 = u : \)
\[
\int_a^b (u(t))^2 dt \rightarrow \min ,
\]
\[
\begin{cases}
\dot{x}(t) = 1 + (y(t))^2 , \\
\dot{y}(t) = u(t).
\end{cases}
\]

11
From Theorem 4.1 one gets the following necessary conditions for the problem to be quasi-invariant under the one-parameter transformation $h^s = (T, X, Y, U)$:

\[
\begin{align*}
\frac{d}{dt} \frac{\partial F}{\partial s} |_{s=0} &= 2u \frac{\partial U}{\partial s} |_{s=0} + u_2 \frac{d}{dt} \frac{\partial T}{\partial s} |_{s=0} \\
\frac{d}{dt} \frac{\partial X}{\partial s} |_{s=0} &= 2y \frac{\partial Y}{\partial s} |_{s=0} + (1 + y^2) \frac{d}{dt} \frac{\partial T}{\partial s} |_{s=0} \\
\frac{d}{dt} \frac{\partial Y}{\partial s} |_{s=0} &= \frac{\partial U}{\partial s} |_{s=0} + u \frac{d}{dt} \frac{\partial T}{\partial s} |_{s=0} .
\end{align*}
\]

These conditions are satisfied with $F = 0$, $T = t(1 - 2s)$, $U = u(1 + s)$, $X = x + 2s(t - 2x)$, and $Y = y(1 - s)$, for which the problem is quasi-invariant:

\[
L \circ h^s \frac{d}{dt} T = u^2 (1 + s)^2 (1 - 2s) = u^2 - (3 + 2s)u^2 s^2 = L + o(s),
\]

\[
\varphi_1 \circ h^s \frac{d}{dt} T = [1 + y^2(1 - s)^2] (1 - 2s) = \frac{d}{dt} [x + 2s(t - 2x)] + (5y^2 - 2y^2 s^2) s^2 = \frac{d}{dt} X + o(s),
\]

\[
\varphi_2 \circ h^s \frac{d}{dt} T = u(1 + s)(1 - 2s) = u(1 - s) - 2us^2 = \frac{d}{dt} Y + o(s).
\]

From Theorem 5.1 the following conservation law holds:

\[
2\psi_x (t - 2x(t)) - \psi_y y(t) + 2Ht \equiv \text{constant},
\]

where $H = \psi_0 (u(t))^2 + \psi_x [1 + (y(t))^2] + \psi_y (t)u(t)$.

In the following two examples we establish conservation laws for the time-optimal problem.

**Example 6.3** (*n = 4, m = 1*). Let us consider the minimum-time problem under the control system

\[
\begin{align*}
x_1(t) &= 1 + x_2(t), \\
x_2(t) &= x_3(t), \\
x_3(t) &= u(t), \\
x_4(t) &= (x_3(t))^2 - (x_2(t))^2.
\end{align*}
\]

In this case the Lagrangian is given by $L = 1$ and in order to satisfy condition 6 of the fundamental invariance theorem we fix $T = t$ (no transformation of the time-variable) and $F \equiv 0$. The functional is invariant and condition 6 of Theorem 4.1 simplifies to

\[
\begin{align*}
\frac{d}{dt} \frac{\partial X_1}{\partial s} |_{s=0} &= \frac{\partial X_2}{\partial s} |_{s=0} \\
\frac{d}{dt} \frac{\partial X_2}{\partial s} |_{s=0} &= \frac{\partial X_3}{\partial s} |_{s=0} \\
\frac{d}{dt} \frac{\partial X_3}{\partial s} |_{s=0} &= \frac{\partial U}{\partial s} |_{s=0} \\
\frac{d}{dt} \frac{\partial X_4}{\partial s} |_{s=0} &= -2x_2 \frac{\partial X_2}{\partial s} |_{s=0} + 2x_3 \frac{\partial X_3}{\partial s} |_{s=0}.
\end{align*}
\]

12
It is now a simple exercise to conclude that the problem is quasi-invariant, in the sense of Definition 5.3 under $X_1 = (x_1 - t)s + x_1$, $X_2 = x_2(s + 1)$, $X_3 = x_3(s + 1)$, $X_4 = x_4(2s + 1)$, $U = u(s + 1)$:

$$
\frac{d}{dt} X_1 = \frac{d}{dt} [(x_1 - t)s + x_1] = (x_1 - 1)s + x_1 = x_2s + x_2 + 1 = 1 + X_2 ,
$$

$$
\frac{d}{dt} X_2 = \frac{d}{dt} [x_2(s + 1)] = x_2(s + 1) = x_3(s + 1) = X_3 ,
$$

$$
\frac{d}{dt} X_3 = \frac{d}{dt} [x_3(s + 1)] = u(s + 1) = U ,
$$

$$
\frac{d}{dt} X_4 = \frac{d}{dt} [x_4(2s + 1)] = x_4(2s + 1) = (x_3^2 - x_2^2)(2s + 1) = X_3^2 - X_2^2 - o(s) ,
$$

with $o(s) = s^2 (x_3^2 - x_2^2)$. One obtains from Theorem 5.1 the conservation law

$$
\psi_1(t) (x_1(t) - t) + \psi_2(t)x_2(t) + \psi_3(t)x_3(t) + 2\psi_4(t)x_4(t) \equiv \text{constant} . \quad (16)
$$

**Example 6.4** $(n = 3, m = 1)$. We consider now the time-optimal problem $(L = 1)$ with the control system

$$
\begin{cases}
\dot{x} = 1 + y^2 - z^2 , \\
\dot{y} = z , \\
\dot{z} = u .
\end{cases}
$$

From the fundamental invariance theorem one can easily get the one-parameter transformation $h^*(t, x, y, z, u) = (t, 2(x - t)s + x, y(s + 1), z(s + 1), u(s + 1))$, for which the problem is quasi-invariant $(F \equiv 0)$:

$$
\frac{d}{dt} X = \frac{d}{dt} [2(x - t)s + x] = (2s + 1)(y^2 - z^2) + 1 = 1 + Y^2 - Z^2 - o(s) ,
$$

$$
\frac{d}{dt} Y = \frac{d}{dt} [y(s + 1)] = z(s + 1) = Z ,
$$

$$
\frac{d}{dt} Z = \frac{d}{dt} [z(s + 1)] = u(s + 1) = U ,
$$

with $o(s) = s^2 (y^2 - z^2)$. The first integral associated to the transformation is

$$
2\psi_x(x - t) + \psi_y y + \psi_z z . \quad (17)
$$

In Examples 6.3 and 6.4 if instead of the time-optimal problem one consider problem (P) with $J[u(\cdot)] = \int^b_a u(t)dt \rightarrow \text{min}$, the same parameter-transformations are in order choosing appropriate functions $F$: $F = sx_3$ and $F = sz$ respectively. The new functionals become invariant up to an exact differential and the terms $\psi_{ux_3}$ and $\psi_{uz}$ must be added respectively to the conservation law (16) and to the constant of the motion (17).
